OPENING LECTURE

CANCER NEOANTIGENS AS TARGETS FOR NATURAL AND THERAPEUTIC ANTI-TUMOR RESPONSES

ROBERT D. SCHREIBER, PH.D., Andrew M. and Jane M. Bursky
Washington University School of Medicine, St. Louis, USA.

Our previous work led to the elaboration of strong experimental data demonstrating the existence of a cancer immunoediting process that functions in both mouse models of cancer and human cancer patients. In the course of these studies we used a combination of exome sequencing and epitope prediction algorithms to show that tumor specific mutant proteins expressed in highly immunogenic d42m1 tumor cells derived from methylcholanthrene (MCA) treated immunodeficient mice represent immunodominant, tumor specific mutant antigens (TSMA) for $CD8^+$ T cells and that immunoselection is a major mechanism underlying the immunoediting process. More recently, we used a similar approach to identify tumor neoantigens in progressively growing T3 MCA sarcomas that render these mouse tumors susceptible to T cell-dependent checkpoint blockade immunotherapy. This work lead to the identification of two immunodominant neoantigens among the 700 point mutations in T3 tumor cells encoding mutant Laminin α subunit 4 (mLama4) and a mutant glucosyltransferase (mAlg8). Therapeutic vaccination of mice bearing established T3 tumors with synthetic long peptides (SLP) vaccines consisting of mLama4 plus mAlg8 peptides plus poly IC resulted in tumor rejection. The therapeutic protection afforded by the SLP vaccine was equal to that induced by checkpoint blockade therapy. Since we did not see evidence of T cell responses to other T3 TSMA, we explored whether the immunodominant antigens masked responses to weaker TSMA. Using CRISPR/Cas9, we reverted mLama4 and mAlg8 back to their nonimmunogenic wild type counterparts in T3 tumor cells. The tumor cells lacking mutant forms of either Lama4 or Alg8 remained susceptible to checkpoint blockade therapy with evidence of TIL skewing towards the remaining TSMA. We then generated T3 tumor cells lacking both mLama4 and mAlg8. The "fixed" T3 tumor cells also remained susceptible to anti-PD-1/anti-CTLA-4-mediated rejection, with evidence of enhanced T cell responses to at least two additional TSMAs—a point mutant form of Gapvd1 and a second novel mutant protein caused by an indel. We are currently testing whether SLP vaccines comprised of these two subdominant TSMA can effectively treat mice bearing either parental or "fixed" T3 tumors. We have also explored the minimal TSMA requirement for immune mediated tumor rejection. Using oncogene driven sarcomas that were completely devoid of mutant neoantigens, we found that protective immune responses to tumors requires the presence of both MHC-I and MHC-II restricted epitopes. The implications of these findings to development of effective neoantigen vaccines will be discussed.

LECTURE II

INFLAMMATION, METABOLISM AND CANCER LINKED TO AP-1(FOS/JUN) EXPRESSION

ERWIN F. WAGNER et al.
CNIO, Madrid, Spain

Our studies aim to analyze gene function in healthy and pathological conditions, e.g. in tumour development, using the mouse as a model organism, but also employing patient-derived samples. Specifically, the functions of the AP-1 (Fos/Jun) transcription factor complex regulating cell proliferation, differentiation and oncogenesis, as well as the cross-talk between organs are being investigated. The goal is to define molecular pathways leading to disease/cancer development and to identify novel therapeutic targets. We focus on elucidating a causal link between inflammation, cancer and AP-1 (Fos/Jun) expression using cell type-specific, switchable genetically engineered mouse models. We are also developing and characterizing new genetically engineered mouse models (GEMMs) for cancer and human diseases, such as for bone loss, fibrosis and psoriasis, and applying these to preclinical studies.

I will focus in my talk on recent studies towards understanding liver and skin pathologies at the cross-road between inflammation, metabolism and cancer, and will discuss the adverse effects of cancer cachexia, a deadly wasting syndrome and metabolic impairment with systemic manifestations frequently observed in cancer patients.

LECTURE III

CLOSING RIFTS TO OPEN NEW HORIZONS: A ´SWEET TALE´ OF TOLERANCE AND IMMUNITY FROM BASIC DISCOVERY TO DRUG DESIGN

GABRIEL A. RABINOVICH et al

Laboratorio de Inmunopatología, Instituto de Biología y Medicina Experimental (IBYME, CONICET) y Facultad de Ciencias Exactas y Naturales, Universidad de Beunos Aires, Argentina.

In the postgenomic era, the study of the glycome- the whole repertoire of saccharides in cells and tissues- has enabled the association of unique glycan structures with specific physiological and pathological processes. The responsibility for deciphering this biological information is assigned to endogenous glycan-binding proteins or lectins whose expression is regulated at sites of inflammation, infection and tumor growth. Galectins, a family of highly conserved glycan-binding proteins, control immune and vascular signaling programs, by modulating reorganization, clustering and signaling threshold of relevant glycosylated receptors. Our laboratory investigates the molecular interactions between endogenous galectins and glycans leading to the control of immune tolerance and homeostasis. In the past years, we identified essential roles for galectin-1 (Gal-1), a proto-type member of this family, in tolerogenic circuits operating during tumor growth, microbial invasion and resolution of inflammation associated to autoimmune and allergic disorders, neurodegeneration, pregnancy and cardiovascular diseases. Mechanistically, this endogenous lectin acts by selectively dampening Th1 and Th17 responses, instructing the differentiation of tolerogenic dendritic cells, promoting the expansion of regulatory T cells, favoring M2 macrophage polarization and modulating eosinophil trafficking. Moreover, our studies identified a glycosylation-dependent, Gal-1-mediated program that links tumor hypoxia, immunosuppression and vascularization and hinders success of anti-angiogenic and immunotherapeutic modalities. These observations, confirmed in a variety of experimental settings and human patient samples, prompted us to generate and validate a set of anti-Gal-1 mAb aimed at overcoming cancer immunosuppression, preventing aberrant angiogenesis and reinforcing antimicrobial responses. Moreover, using an interdisciplinary approach ranging from computational modeling, protein engineering, and cell biology, we designed and validated stable galectin-tailored variants aimed at potentiating tolerogenic circuits and promoting resolution of autoimmune inflammation. In conclusion, our studies contributed to elucidate novel pathways via which endogenous galectins translate glycan-encoded information into unique signaling programs, findings that bring unifying principles to the diverse fields of immune regulation, oncology and vascular biology. These observations have opened new possibilities for development of therapeutic strategies aimed at potentiating antitumor responses, reinforcing antimicrobial immunity and limiting autoimmune inflammation.

LECTURE VI

THE BIOCHEMISTRY OF G PROTEIN-COUPLED RECEPTOR SIGNALING

JEFFREY BENOVIC

Thomas Jefferson University, Jefferson Health, USA

G protein-coupled receptors (GPCRs) regulate the activity of numerous effector molecules and play an essential role in coordinating the ability of cells to rapidly respond to their environment. Agonist binding to a GPCR activates heterotrimeric G-proteins, which mediate downstream signaling and ultimately a physiological response. GPCR signaling is dynamic and undergoes rapid regulation by GPCR kinases (GRKs), which specifically phosphorylate activated GPCRs, and arrestins, which bind to GRK-phosphorylated GPCRs to promote receptor desensitization and endocytosis as well as arrestin-mediated signaling. Significant structural and dynamic insight on GPCR interaction with G-proteins, arrestins and GRKs has been gained in recent years. In my presentation, I will highlight our recent efforts to gain mechanistic insight on GRK interaction with GPCRs. These studies have focused on GRK5 interaction with the b2-adrenergic receptor and reveal key mechanistic features of how these two proteins interact, and how this interaction leads to conformational changes that are essential for mediating receptor phosphorylation. I will also discuss our recent efforts to utilize small molecules to preferentially bias GPCR signaling to either the G-protein or arrestin pathways. Such biased signaling provides insight on signaling dynamics and has the potential to improve the treatments of diseases involving GPCRs.

LECTURE V

TUMORIGENESIS REGULATION BY STRESS KINASE SIGNALING

ANGEL R. NEBREDA
ICREA and Institute for Research in Biomedicine (IRB Barcelona), Barcelona Institute of Science and Technology, Barcelona, Spain.

The ability to properly interpret stress signals is critical for cell survival. One of the pathways that play a key role in the regulation of stress responses is orchestrated by the MAPK family member p38α. Interestingly, this pathway not only regulates the cellular responses to stress but can also integrate signals that affect many other cellular processes in a cell context- and cell type-specific manner. Genetically modified mice have helped to elucidate in vivo functions for p38α signaling and have also provided insights into how this pathway can suppress tumor initiation. It is now well established that normal epithelial cells rely on p38α signaling to engage various tumor suppressor mechanisms, including cell cycle arrest, apoptosis induction or cell differentiation. However, in contrast with other tumor suppressors, p38α does not seem to be usually mutated in human tumors, and there is evidence that p38α signaling can sometimes facilitate the proliferation, survival and dissemination of cancer cells, therefore enabling tumor progression. Of note, p38α signaling has been also implicated in the resistance of cancer cells to some chemotherapeutic drugs. We have used mouse models to investigate the roles of the p38α pathway in the progression of different types of tumors, and obtained genetic evidence that transformed epithelial cells often rely on p38α signaling for survival and proliferation. Experiments using chemical inhibitors further support a role for p38α signaling in tumor development in vivo. I will present results showing how the p38α pathway can contribute to tumor development, both by regulating the homeostasis of cancer cells and by modifying the tumor microenvironment. I will also illustrate how this information can be used to develop new potential therapies for cancer.

THE STRUCTURE AND FUNCTION OF THE RIBOSOME COMPLEXES WITH VARIOUS PROTEIN FACTORS AND ANTIBIOTICS

Thomas A. Steitz
Department of Molecular Biophysics & Biochemistry and Department of Chemistry at Yale University, and the Howard Hughes Medical Institute, New Haven, CT (USA)

We have obtained many insights into the structural basis of ribosome function in protein synthesis from our structural studies of the large ribosomal subunit as well as the 70S bacterial ribosome, and their complexes with substrates, protein factors or antibiotics. These have elucidated the mechanism by which this ribozyme catalyzes peptide bond formation and the specificity and mode of its inhibition by antibiotics.

We have obtained the structure of the complex of the 70S ribosome with tRNAs and EF-G in a previously unseen compact conformation. This compact conformation of EF-G, unlike the elongated one, allows the simultaneous binding of a tRNA in the A site and EF-G. We propose that the conversion of the compact to the elongated conformations of EF-G is responsible for tRNA translocation. The structures of the 70S ribosome with the factor EF4 (LepA) with tRNA bound in the P site or in the A and P sites provide the first insights into EF4's possible role in protein synthesis. Our structure of the 70S ribosome bound with a ribosome rescue protein (yaeJ) shows how it rescues stalled ribosomes.

The structures of some of our antibiotic complexes have been used by Rib-X Pharmaceuticals, Inc. (now Melinta Therapeutics) of New Haven to develop new potential antibiotic compounds that are effective against MRSA, one of which has successfully completed phase II clinical trials. Recently, we have obtained the structures of the 70S ribosome complexed with various oligopeptides that bind in the peptide tunnel, but in the opposite direction from peptides being synthesized; these structures might enable the creation of other new antibiotics.

CONFERENCE I

BIOINFORMATICS APPLICATIONS: WHERE BIOPHYSICS AND GENOMICS MEET

MARCELO A. MARTI.
Departamento de Química Biológica e IQUIBICEN-CONICET, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires.

Next Generation Sequencing technologies have driven biology in the big-data paradigm, with genomic information growing exponentially on a daily basis. Bioinformatics is the core business that allows conversion of this

information into biological knowledge, and among most important issues are genotype-phenotype inference relationships. Predicting how genetic differences impact a given protein function ate the molecular level, and thus phenotypic outcome, is important for understanding among other issues: antibiotic resistance and development of new drugs, enzyme selectivity and specificity, and human genetic borne diseases.
In the present talk I will show examples of several in-house developed bioinformatic applications that allow structure based physico-chemical characterization of proteins and protein variants at genomic wide scale. Specifically I will show: i)how to select best protein targets from a given pathogen genome to develop new drugs- in the present case Mycobacterium tuberculosis-, and how to seamlessly select possible "commercially available" inhibitors for the desired target; ii) how to predict subtle differences in protein function (mainly oxygen affinity) in the whole hemoglobin protein superfamily; and iii) how to predict whether a newly found human mutation is likely to be pathogenic

CONFERENCE II

LESSONS FROM THE ANALYSIS OF THE IMMUNE RESPONSE TO PLASMODIUM FALCIPARUM

ANTONIO LANZAVECCHIA
Institute for Research in Biomedicine, Università della Svizzera italiana, Switzerland

We use cell culture-based high-throughput methods to interrogate human memory B cell and plasma cell repertoires and to isolate antibodies selected on the basis of their neutralizing potency and breadth. Relevant examples are antibodies that neutralize all influenza A viruses or even four paramyxoviruses (Science 2011, 333:850; Nature 2013, 501:439). By targeting conserved structures, these broadly neutralizing antibodies are less prone to select escape mutants and are promising candidates for prophylaxis and therapy of infections, as well as tools for vaccine design. While searching for antibodies that broadly react with malaria variant antigens, we discovered a new mechanism of antibody diversification, which relies on templated insertions of genomic DNA sequences into immunoglobulin genes, followed by somatic mutations (Nature 2015, 529:105). Indeed, human monoclonal antibodies that recognize erythrocytes infected by different P. falciparum isolates acquired broad reactivity through a novel mechanism of insertion between the V and DJ segments of the entire 98 amino acid collagen-binding domain of LAIR1, an immunoglobulin superfamily inhibitory receptor encoded on chromosome 19. More recently, we studied two large cohorts of individuals living in malaria-endemic regions and found that 5-10% of malaria-exposed individuals, but none of the European blood donors tested, have high levels of LAIR1-containing antibodies that dominate the response to infected erythrocytes (Nature 2017, 548:597). The study also revealed different modalities of LAIR1 insertion that lead to public and dominant antibodies against infected erythrocytes. Sequencing of the switch regions of memory B cells from European blood donors revealed frequent templated inserts originating from transcribed genes that, in rare cases, comprised exons with orientations and frames compatible with expression. Our data suggest that insertion of templated DNA represents an additional mechanism of antibody diversification that can be selected in the immune response against pathogens.

CONFERENCE III

NEDDYLATION AS A NEW ESSENTIAL POST-TRANSLATIONAL MODIFICATION: ITS ROLE ON NEURONAL DEVELOPMENT AND METABOLISM AS A PROOF OF PRINCIPLE

DAMIAN REFOJO
Instituto de Investigación en Biomedicina de Buenos Aires,
CONICET-Instituto Partner de la Sociedad Max Plank, Buenos Aires, Argentina.

Neddylation is anubiquitylation-like pathway that controls proliferation by covalently conjugating Nedd8 a subset of ubiquitin E3 ligases called Cullins, which target different substrates involved in the control of cell cycle and duplication. Even though Nedd8 (NEDD8 neural precursor cell expressed, developmentally down-regulated 8) was originally cloned from brain tissue its role in neurons as well as in others, non-replicating postmitotic cells, remains almost entirely unexplored.
We recently found that Nedd8 is ubiquitously expressed in the brain and that neddylationincreases along postnatal brain development and with neuronal maturation. Nedd8 conjugation is active in mature synapses, where many proteins are neddylated both at pre- and post-synaptic compartments. Interestingly, neddylationis essential for normal development of excitatory (but not inhibitory) synapses during neuronal maturation and as well as spine stability in mature neurons.
Using different biochemical tools, we found that PSD-95 the most abundant scaffolding protein of the post-synaptic density is neddylated and that neddylation on Lys202 in its second PDZ domain is required for the proactive

role of the scaffolding protein in spine maturation and AMPA synaptic transmission. Finally, we developed Nae-1$^{CamKIIα\text{-}CreERT2}$ mice, in which neddylation is conditionally ablated specifically in adult excitatory forebrain neurons and only upon tamoxifen administration. These mice showed synaptic loss, impaired neurotransmission and severe cognitive deficits.

In follow-up studies we found that neddylation also exerts critical roles in early neuronal development and identified new neddylated targets that would help explain the underlying proactive effects of neddylation in neuronal maturation. A new potential mechanism of action of the neddylation pathway in neuronal maturation would be discussed.

These studies prompted us to consider that the Nedd8 conjugation pathway might play, besides its well-known role in cell cycle and proliferation,additional functions along cell differentiation and exert tissue-specific roles in cells with different identities. In order to explore this possibility we studied the potential influence of the neddylation pathway in adipocyte differentiation and biology. By using cell culture and mouse genetics tools we found that neddylation is also a critical controller of adipocyte maturation and that indeed this pathway is essential for developing high-fat diet induced-obesity. Interestingly the administration of a recently developed inhibitor of the neddylationpathway reduces body-weight and fat accumulation in obese mice, opening new opportunities and therapeutic avenues for treating obesityand associated metabolic changes.

Altogether, these results obtained in different cell types and maturation stepsmight arguably represent a proof of principle of a more general possibility: that neddylation operates as a relevant, so far unexplored post-translational regulatory pathway controlling diverse structural and functional aspects of cells undergoing differentiation as well as cell identity-specific functions in fully differentiated cells.

CONFERENCE IV

RECENT CLINICAL STUDIES FOR THE ETIOLOGIC TREATMENT OF CHRONIC CHAGAS DISEASE: PRECLINICAL ANTECEDENTS, RESULTS AND ALTERNATIVES

JULIO A. URBINA, PH.D.

Emeritus Investigator, Venezuelan Institute for Scientific Research, Caracas, Venezuela.

Chagas disease, a chronic systemic parasitosis caused by the Kinetoplastid protozoon Trypanosoma cruzi, is the first cause of cardiac morbidity and mortality in poor rural and suburban areas of Latin America and the largest parasitic disease burden in the continent, now spreading worldwide due to international migrations. Currently available anti-T. cruzi drugs, the nitroheterocyclic compounds benznidazole and nifurtimox, were developed empirically over 40 years ago and have been shown to be highly effective in acute, congenital and early chronic (pediatric) Chagas disease, but observational studies in the prevalent established chronic disease indicated that their efficacy is significantly lower and variable; furthermore, both drugs have frequent adverse effects that can lead to treatment discontinuation in 10-30% of patients. The BENEFIT study (published in 2016), was the first randomized, double-blind, placebo controlled, multi-centric trial to evaluate the efficacy of benznidazole on the clinical evolution of chronic Chagas' disease patients with cardiac compromise. The results indicated that the drug was able to markedly [but transiently] reduce parasite blood levels, while there was no significant effect on clinical deterioration through 5 years of follow-up. Further analysis of these results showed that were marked differences in the parasitological and clinical efficacy of the drug among the endemic regions included in the study, with a clear correlation of both effects, in concordance with the parasite persistence hypothesis of chronic Chagas' disease pathogenesis. The TRAENA trial (to be published in 2017) was a randomized, double blind, placebo controlled trial aimed at evaluate the parasitological and clinical efficacy of benznidazole in chronic patients from Argentina. The results indicated that there was a very marked reduction of the parasite blood levels up to 12-14 months post-treatment but no significant effect of the drug on the clinical evolution of patients, with a mean follow up of 7 years. Such result could be associated to a delayed relapse of the patients' parasite load, as seen in the BENEFIT study. Ergosterol biosynthesis inhibitors, such as posaconazole and ravuconazole, have been shown to have a potent and highly selective anti-T. cruzi activity in vitro and in animal models. Recent studies have evaluated the safety and efficacy of posaconazole in chronic patients in monotherapy (CHAGASAZOL, 2014) and in combination with benznidazole (STOP CHAGAS, 2017); the results indicated that the drug is much better tolerated than benznidazole but is unable to induce a sustained suppression of parasitemia at the end of the 12 months follow up period; this finding is probably explained by the fact that the systemic exposure of the drug at the dose of the liquid suspension formulation used in these studies (400 mg b.i.d.) is an order of magnitude lower than that attained at the curative dose in animal models. Finally, the results of a study on the safety and efficacy of E1224, a prodrug of ravuconazole in chronic patients from Bolivia were recently published (2017) and indicate that 30% of patients treated with the dose of 400 mg/week for 8 weeks had sustained parasitemia suppression at 12 months post-treatment; pharmacodynamics models derived from the data indicate that such percentage can reach to ca. 80% if the treatment period is extended to 12 weeks or if combined with benznidazole for 4-6 weeks.

CONFERENCE V

MANIPULATING THE TUMOR MICROENVIRONMENT FOR ANTI-CANCER THERAPY

LISA M. COUSSENS,

Department of Cell, Developmental & Cancer Biology, Knight Cancer Institute, Oregon Health & Sciences University, 3181 SW Sam Jackson Park Road, Portland OR 97239-3098.

The concept that leukocytes are critical components of solid tumors is now generally accepted, however, their role(s) in regulating aspects of neoplastic progression, and/or response to cytotoxic, targeted and/or immune therapy is only beginning to be understood. Utilizing de novo mouse models of organ-specific solid tumor development (mammary, cutaneous, and pancreas carcinomas and mesothelioma), we now appreciate that adaptive leukocytes differentially regulate myeloid cell recruitment, activation and effector function, and in turn, activated tumor-infiltrating myeloid cells engage tissue-based programs to foster malignancy, and repress anti-tumor immunity by a diversity of mechanisms. Treatment of tumor-bearing mice with therapeutic agents that disrupt lymphocyte-myeloid cell interaction, myeloid cell activation, or myeloid cell functionality generally slow primary tumor growth kinetics when combined with cytotoxic therapy; however, their impact on metastases is variable. Similar to organ-specific regulatory programs co-opted to foster primary tumor growth, regulation of metastatic seeding and outgrowth is also regulated by tissue- and organ-specific mechanisms. Based on this, it stands to reason that therapeutic strategies may not be efficacious in both primary and metastatic locations. To be presented will be our recent insights into organ and tissue-specific regulation of primary and metastatic cancer development by adaptive and innate immune cells, and new studies evaluating how attenuating protumor properties of select lymphoid and myeloid cells can be exploited to enhance therapeutic responses to cytotoxic and immune-based therapy.

Komen Foundation, the Breast Cancer Research Foundation, the Brenden-Colson Center for Pancreatic Health, and a Stand Up To Cancer – Lustgarten Foundation Pancreatic Cancer Convergence Dream Team Translational Research Grant.

CONFERENCE VI

DEFINING THE CELLULAR AND MOLECULAR PROCESSES CRITICAL FOR PRIMATE OVARIAN FUNCTION AND FERTILITY

JON D. HENNEBOLD

Division of Reproductive & Developmental Sciences, Oregon National Primate Research Center, Beaverton, OR, USA; Department of Obstetrics & Gynecology, Oregon Health & Science University, Portland, OR, USA.

The midcycle surge of pituitary derived luteinizing hormone (LH) initiates cellular activities critical for ovulation, which includes follicle rupture and the release of a fertilizable oocyte, reinitiation of oocyte meiosis, as well as the development of the corpus luteum. While it is well documented that LH is the key endocrine factor responsible for orchestrating the events necessary for ovulation, downstream LH-regulated activities have yet to be fully characterized, especially in the primate ovarian follicle. Our laboratory has recently utilized high-throughput methods to systematically identify LH-dependent processes in the rhesus macaque follicle that play a role in ovulation and the release of an oocyte that is competent to undergo fertilization and embryonic development. Genomic studies were performed on follicles collected from rhesus macaques undergoing controlled ovulation (COv) protocols. The COv protocol is initiated after the selection of a single dominant follicle has occurred, which is determined by the presence of circulating estradiol above a threshold level (~100 pg/ml). At this point, a gonadotropin-releasing hormone antagonist is administered to prevent a spontaneous LH surge. Low levels of gonadotropins (i.e., follicle stimulating hormone, LH) are administered to promote continued survival and development of the follicle. A bolus of human chorionic gonadotropin (hCG) administered 48 hours later initiates events that lead to ovulation. The complete rhesus macaque transcriptome was then characterized in COv derived follicles isolated prior to (0 hour) and 12, 24, and 36 hours after hCG delivery. The 36 hour time point included follicles that were collected just prior to rupture and those that had ovulated. Of the genes whose mRNA levels change significantly through the periovulatory interval, a current area of investigation for the laboratory includes defining the role LH-regulated immune factors and cytokines play in ovulation. A second project in the laboratory includes using a comprehensive metabolomics assessment of follicular fluid obtained 36 hours post-hCG from individual follicles of rhesus macaques undergoing a controlled ovarian stimulation (COS) protocol to identify intrafollicular determinants of oocyte quality. The mature metaphase II oocyte from each follicle was then subjected to in vitro

fertilization, with outcomes being categorized as failed fertilization (did not cleave), arrested post-fertilization development (did not progress past the compact morula stage), or fertilization and development to the blastocyst stage. From these studies, it was noted the follicular fluid concentrations of specific compounds correlated with the potential of the resident oocyte to fertilize and develop to the blastocyst stage. Current efforts in the laboratory include determining the role the molecular and cellular pathways responsible for generating these compounds play in impacting the potential of the resident oocyte to undergo fertilization and embryonic development. Thus, specific cellular and molecular processes that serve to coordinate LH activities in the primate follicle were successfully identified using both genomic and metabolomics approaches, which in turn will likely yield insight into the control of fertility in women.

CONFERENCE VII

HEALTH CARE FOR SEXUAL DIVERSITY AT THE PUBLIC HOSPITAL: 12 YEARS OF EXPERIENCE

DR. ALBERTO NAGELBERG

Since 2005, the Health Care Team for Transgender People (Grupo de Atención de Personas Trans- GAPET) from Carlos Durand Hospital, has been working on a multidisciplinary basis. After the approval of the Gender Identity Law in 2012, medical consultations have increased significantly.

We use the term “trans male” (TM) to refer to a person who was assigned female at birth but with a male gender identity, and “trans female” (TF), to biological males with a female gender identity. However, due to the existence of multiple variants in gender identity beyond this binary, a personalized treatment for each case is required.

Even in current days, there are several myths and stigmas around them, majorly due to misinformation.

In order to know the background of the trans population seen by our team, we have reviewed clinical reports of 510 patients (147 TM and 363 TF) assessed between 2005 and 2017.

Most of them showed an adequate insertion in their family, social, educational and working environments.

High prevalence of tobacco use (mainly among TM), equal prevalence of marijuana consumption in both groups, and higher rates of heavy drugs among TF. No significant alcohol consumption in the majority. Prevalence of AIDS was considerable among TF, but almost non- existent among TM. Both groups had backgrounds on self-medication, much higher among TF. Both TF and TM showed a low desire towards fertility preservation. High levels of ideation and suicidal attempts in both groups, a higher percentage of ideation among TF and a higher prevalence of suicidal attempts among TM.

Most TM would undergo a breast reassignment surgery, in comparison with a low percentage among TF, who showed satisfaction with the cross - sex hormone therapy. Almost 70% seek for genital reassignment surgery, whereas the others prefer to keep their birth assigned genitality.

Are we endocrinologists, skilled and trained enough to deal with consultations of transgender patients efficiently?

In order to find the answer to this question, we conducted two kinds of anonymous surveys on line. One of them aimed at endocrinologists and fellows, the other one aimed at endocrinologists career directors. Most of the endocrinologists surveyed had received consultations from trans patients; this shows a high demand for assistance. We have also observed a positive attitude to see these patients with almost no rejection towards the subject. Training times proved to be insufficient, leading to a middle to low confidence on counselling patients about legal and practice issues. In most cases, the non-medical staff had not received any training at all, making it difficult for the patients to join the health care system. The need to implement programs on transgender medicine was considered relevant among career directors. However, most of them shared the view that the assistance to those patients is not easily available or inclusive in our country due to prejudices on the subject and lack of experience as well, which we understand is contradictory to the “positive attitude” expressed by the surveyed endocrinologists.

CONFERENCE VIII

NOVEL APPROACHES FOR GENOME EDITING IN TRYPANOSOMES

ROBERTO DOCAMPO

Center for Tropical and Emerging Global Diseases and Department of Cellular Biology, University of Georgia, USA

Genome editing by CRISPR (clustered regularly interspaced short palindromic repeats)/Cas9 (CRISPR-associated gene 9) system has revolutionized biological research because it is highly flexible and allows for targeted DNA cleavage (double-strand breaks) and genome editing (repair usually by non-homologous end joining or by homology-directed repair) in a variety of eukaryotic cells. The endonuclease cleavage specificity

is guided by RNA sequences, allowing editing to be targeted simply by engineering the guide RNA sequence that is transfected along with the Cas9 endonuclease. Initially discovered as an adaptive prokaryotic immune system, CRISPR/Cas9 has been repurposed for genome editing in a broad range of organisms. Protist parasites are unicellular organisms producing important diseases that affect millions of people and animals around the world. Vaccines or effective treatments are not available for many of these diseases, such as malaria, Chagas disease, leishmaniasis and cryptosporidiosis. The adaptation of the CRISPR/Cas9 method to several parasites is becoming extremely useful for functional studies of proteins, characterization of metabolic pathways, and identification of new chemotherapeutic targets. We will present recent studies where the CRISPR/Cas9 system was adapted to protist parasites, emphasizing studies relevant to Trypanosoma cruzi, the agent of Chagas disease, as well as other approaches, such as the use of metabolically activated ribozymes, used for genome modifications in different trypanosomatids.

CONFERENCE IX

CONFERENCIA "ALBERTO TAQUINI"

MECHANISM-BASED TARGET IDENTIFICATION AND DRUG DISCOVERY IN CANCER RESEARCH: RELEVANCE OF CAMP AND COUPLED SIGNALING PATHWAY

CARLOS DAVIO

Instituto de Investigaciones Farmacológicas, (ININFA-UBA-CONICET) y Departamento de Farmacología, Facultad de Farmacia y Bioquímica, UBA, Buenos Aires, Argentina.

The goal of our laboratory is to exploit the emerging information on deregulated signaling circuitries and individual genomic and molecular alterations to develop new precision therapies to prevent and treat cancer. Specifically, we have focused on the study of cAMP and its coupled signal transduction pathway, and recently on the use of different approaches to study Pancreatic Ductal Adenocarcinoma (PDAC) initiation and progression. PDAC is one of the most lethal types of tumors and one of the biggest therapeutic challenges for modern oncology. Despite the recent improvement in survival, the 5-year survival rate remains below 5-8%. Therefore, there is a great clinical need to identify key molecular and cellular regulators of tumor progression and invasion in order to develop new therapeutic strategies. The carcinogenic process of pancreatic cancer accounts for an accumulation of mutations and genetic lesions in signaling pathways linked to cell proliferation, motility and survival. In the last few decades, several mutations leading to the activation of oncogenes (such as KRAS, GNAS, and BRAF) and the inhibition of tumor suppressor genes (such as p16/CDNKN2A, TP53, SMAD4/DPC4, and BRCA2) have been identified. These mutations are present in the earliest-stages and lowest-grade premalignant lesions of the disease, suggesting that they could be essential for its development/progression and therefore, conceivably therapeutic targets. Interestingly, frequent activating mutations in GNAS, gene encoding for the stimulatory Gα subunit (Gαs), are not the only alterations on the canonical cAMP signaling pathway described in PDAC. Recent studies identified that 59% of the tested human PDAC samples exhibit an elevated Gαs expression compared to normal tissues, and 72% show an increment in the expression of phosphorylated substrates of cAMP-dependent kinase (PKA), a downstream effector of the Gαs-protein-coupled receptor-cAMP signaling pathway. Altogether, these observations indicate that cAMP cascade is commonly activated in PDAC, and suggest an oncogenic potential for this signaling pathway. Nonetheless, this assumption points to an intriguing paradox based on the fact that the activation of cAMP pathway has been classically associated with inhibition of cell proliferation and migration in PDAC. Due to the critical role of cAMP in cellular biology, the time-course levels of this second messenger are strictly regulated by several mechanisms, including its degradation by phosphodiesterases, its compartmentalization, the desensitization of GPCR, and its extrusion to the extracellular compartment mainly mediated by the Multidrug Resistance-Associated Protein 4 (MRP4/ABCC4). In recent years, numerous publications describe the anti-proliferative effects of MRP4 inhibition, its potential as a marker of poor prognosis and its up-regulation in several tumors. However, little is known about the mechanisms involved in the anti-proliferative effects of MRP4 inhibition and there are limited studies of its potential as a therapeutic target. We have recently described that enhanced intracellular cAMP levels upregulate MRP4 expression through the activation of cAMP/Epac/Rap1 signaling pathway. Considering the frequent cAMP-signaling deregulation observed in PDAC, we hypothesize that pancreatic cancer cells could be "addicted" to high levels of MRP4, relying on active cAMP extrusion to provide a survival advantage, and therefore highlighting a therapeutically exploitable difference between cancerous and normal cells. In this study we showed that MRP4 expression is upregulated in human pancreatic cancer and may influence patient outcome. MRP4 inhibition abrogated cell migration and proliferation in vitro by both, activating the cAMP/Epac/Rap1 signaling pathway and reducing extracellular cAMP levels. Interestingly, the extruded cAMP acted as an autocrine/paracrine mitogenic signal and silencing MRP4 strongly impaired tumor growth and tumorigenicity in a mouse xenograft model. Our results strongly indicate

that MRP4 could represent an excellent therapeutic target for pancreatic ductal adenocarcinoma.

CONFERENCE X

MOLECULAR BASIS OF T CELL EXHAUSTION: INSIGHTS FOR IMMUNOTHERAPY

E. JOHN WHERRY

Department of Microbiology and Institute for Immunology. Perelman School of Medicine, University of Pennsylvania, Philadelphia, Pennsylvania, USA

T cell exhaustion is common during chronic infections, cancer and prevents optimal immunity. Exhausted T cells (T_{EX}) are defined by the poor ability to perform effector functions, low proliferative capacity, inefficient survival following antigen stimulation and a unique transcriptional program that is conserved between different chronic infections, species and is also present in cancer. In addition, it has become clear that T_{EX} co-express multiple inhibitory receptors that negatively regulate their function. Indeed, receptors such as PD-1 have become major targets of clinical immunotherapies in cancer and infectious disease aimed at re-invigorating T_{EX}. Our work has defined a transcriptional circuit involving the transcription factors T-bet and Eomesodermin (Eomes) that controls progenitor and terminal subsets of T_{EX}. Moreover, features of these subsets allow tracking of T_{EX} in humans during immunotherapy. One observation from these studies is that a key surrogate of reivingoration of T_{EX} responses is a population of $Eomes^{Hi}$ $PD\text{-}1^{Hi}$ exhausted CD8 T cells. The use of this subset of CD8 T cells as a biomarker is explored. Moreover, we have examined the durability of re-invigoration of T_{EX} in both humans and mice and found that the effectiveness of PD-1-based checkpoint blockade may be limited by the epigenetic inflexibility of T_{EX}. Ultimately, a more precise molecular understanding of T cell exhaustion should lead to novel and more robust clinical interventions to reverse exhaustion in settings of persisting infections and cancer.

CONFERENCE XI

MOLECULAR AND CELLULAR MECHANISMS OF HUMAN VIRAL ONCOGENESIS

ENRIQUE A. MESRI, PH.D.

Miami Center for AIDS Research, Department of Microbiology and Immunology & Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, USA.

Viral cancers account to 12% of all human cancers and occur in their vast majority in the developing world. Viral oncogenesis is an special case for the exquisite adaptation of persistent viruses that subvert physiological host-regulatory pathways in order to ensure their replication and long term survival on the host (1). Oncoviruses carry viral oncogenes that activate the same host signaling pathways regulating growth and apoptosis driving non-viral cancers. This results in the acquisition of hallmarks of cancers that can initiate the process towards full transformation (1). Although infection and oncogenicity are under the control of the immune system, immunosuppression and HIV/AIDS can facilitate the onset of viral cancers induced by oncoviruses such as High risk HPV, EBV and KSHV (1). KSHV; a gamma2-herpesvirus, is the etiologic agent of Kaposi's sarcoma, an AIDS-associated neoplasm characterized by angiogenesis and the proliferation of spindle-like cells (3,5). KSHV encodes viral oncogenes such as the viral G protein coupled receptor (vGPCR) which can drive oncogenesis and angiogenesis by inducing the expression of VEGF (2,3,4,5). Our latest studies on vGPCR and the mechanisms of KSHV in cell and animal models exemplify how molecular and cellular studies on viral oncogenesis can be exploited for both for therapeutic purposes and gaining novel insights on the pathophysiology of viral transformation. We found that KSHV vGPCRand other viral genes activate the host PDGF signaling axis by upregulating PDGFA and B. This results in viral-mediated activation of PDGF-receptor A (PDGFRA), a well knownsarcomagenic driver and a validated therapeutic target in non viral sarcomas, which we found is the receptor tyrosine kinase most activated in Kaposi's sarcoma. We validated PDGFRA as therapeutic target in KS using receptor tyrosine kinase inhibitory drugs, by the use of specific dominant negative constructs and by showing that the vast majority of KS lesions robustly display PDGFRA in its phosphorylated form. We next reasoned that the potent KSHV activation of PDGFRA suggest that this is a critical host factor for KSHV oncobiology. Therefore, KSHV target cells that are progenitors of KS spindle cells should be PDGFRA expressing cells. This led us to the identification of mesenchymal stem cells (MSCs)as KS oncogenic progenitors and the use of murine mesenchymal stem cells (mMSCs) to develop a reproducible and robust system of tumorigenesis that is dependent on expression of PDGFRA as well as external pro-angiogenenic conditions. Using RNAseq analysis and CHIPSeq we found that under pro-angiogenic conditions mMSCs provide an epigenetic landscape permissive for KSHV oncogene expression and cell transformation.

CONFERENCE XII

THE LAST FRONTIER OF ANTIBIOTIC RESISTANCE: AT THE HEART OF PROTEIN EVOLUTION

Guillermo Bahr, Estefania Giannini, Antonela R. Palacios, Ma. Agustina Rossi, Juliana Delmonti, Carolina López, Pablo E. Tomatis, Lisandro J. González and Alejandro J. Vila

Instituto de Biología Molecular y Celular de Rosario (IBR), CONICET – Universidad Nacional de Rosario vila@ibr-conicet.gov.ar

Protein evolution can be described as a walk on sequence space where a fitness value is assigned to each particular sequence. A major challenge to understand the biological mechanisms of protein evolution is the attempt to correlate genotype with phenotype and fitness at a molecular level. This is a complex challenge, involving the assessment of biochemical, biophysical and structural features to many protein variants.

Antibiotic resistance mediated by β-lactamases is an ideal system to study protein evolution, since the chances of a whole organism to survive depend on the availability of a folded, stable and active protein in the proper cellular compartment (the bacterial periplasm).

Metallo-β-lactamases (MBLs) are Zn(II)-dependent β-lactamases that constitute the latest resistance mechanism of pathogenic and opportunistic bacteria against carbapenems, considered as last resort drugs. Zn(II) binding is critical in the bacterial periplasm, not only to activate these enzymes and provide resistance, but also to stabilize the protein scaffold. This phenomenon is not paralleled by in vitro studies. We developed a strategy aimed to correlate the biochemical and biophysical features in purified enzymes with those in the bacterial periplasm, ultimately leading to the selected phenotype, i.e., resistance to antibiotics. This strategy allows us to dissect the molecular features that are tailored by accumulating mutations during evolution. We have applied this approach to in vitro evolved protein in the laboratory, as well as to natural allelic variants selected in clinical strains. This has allowed us to account for the epistatic interactions between mutations at a structural level.

Finally, we have shown that the natural evolutionary landscape of allelic variants of a clinically relevant lactamase (NDM) has been shaped by Zn(II) deprivation conditions as those induced by the host immune response. As a consequence, natural NDM variants with enhanced Zn(II) binding affinity have been selected, overriding the most common evolutionary pressure acting on catalytic efficiency.

CONFERENCE XIII

DON'T STRESS! NEW INSIGHTS INTO STRESS INHIBITION OF MAMMALIAN REPRODUCTION

ALEXANDER S. KAUFFMAN

Department of Reproductive Medicine, University of California, San Diego, La Jolla, CA, USA

Stress disturbs many physiological processes, including reproduction. Indeed, multiple types of stressors, including psychological stress, can negatively impact reproductive status in many mammalian species, including humans. Restraint and/or isolation, commonly-used models of psychosocial stress in mammalian models, reduce luteinizing hormone (LH) and follicle stimulating hormone synthesis and secretion, as well as impair reproductive ovarian cyclicity. To date, little is known about underlying mechanisms for stress suppression of GnRH and downstream LH secretion, especially at the level of the brain. While it is known that psychosocial stress inhibits several hypothalamic or pituitary components of the reproductive axis, including LH secretion, it is less clearly understood how stress regulates reproductive circuits in the brain. Emerging evidence suggests that hypothalamic kisspeptin (encoded by Kiss1) neurons are key components for generating and stimulating GnRH pulse secretion as well as the GnRH/LH surge that elicits ovulation. Thus, it is possible that psychosocial stress—through factors and pathways yet to be determined—impacts kisspeptin neurons, thereby altering downstream LH pulsatility or surge secretion. In addition, recent evidence suggests that the peptide, RFamide-related peptide 3 (RFRP-3, encoded by Rfrp), can inhibit GnRH and LH output and may do so under stressful conditions. We recently conducted several projects in mice to ascertain the effects of acute psychosocial stress or stress hormones on pulsatile and

surge LH secretion and the upstream brain circuits regulating the reproductive axis. Our findings indicate that acute stress or short-term exposure to physiological levels of corticosterone can have profound effects on LH pulses and the positive feedback induction LH surge, in part through regulation at levels upstream of GnRH neurons, either directly or indirectly, through hypothalamic Kiss1 and/or Rfrp neurons. This talk will summarize our recent findings of stress impairment of reproductive status in mouse models and discuss remaining gaps in knowledge.

CONFERENCE XIV

ROLE OF THE ENDOCANNABINOID SYSTEM IN FOOD-INDUCED ADDICTIVE-LIKE BEHAVIOR

RAFAEL MALDONADO

Laboratorio de Neurofarmacología. Universitat Pompeu Fabra. Parc de Recerca Biomèdica de Barcelona. C/ Dr Aiguader, 88. 08003 Barcelona, España.

An increasing perspective conceptualizes obesity and overeating as disorders related to addictive-like processes that could share common neurobiological mechanisms. We aimed at validating an animal model of eating addictive-like behavior in mice, based on the DSM-5 substance use disorder criteria, using operant conditioning maintained by highly palatable chocolate-flavored pellets. For this purpose, we evaluated persistence of food-seeking during a period of non-availability of food, motivation for food, and perseverance of responding when the reward was associated with a punishment. This model has allowed identifying extreme subpopulations of mice related to addictive-like behavior. We investigated in these subpopulations the Epigenetic and proteomic studies have allowed to identify a significant decrease in DNA methylation of CNR1 gene promoter in the prefrontal cortex of addict-like mice, which was associated with an upregulation of CB1 protein expression in the same brain area. The pharmacological blockade of CB1 receptor during the late training period reduced the percentage of mice that accomplished addiction criteria, which is in agreement with the reduced performance of CB1 knockout mice in this operant training. Proteomic studies have identified proteins differentially expressed in mice vulnerable or not to addictive-like behavior in the hippocampus, striatum, and prefrontal cortex. The use of DREADD techniques in this model has now allowed identifying the crucial role of the prefrontal cortex in the development of eating addictive-like behavior. This model provides an excellent tool to investigate the neurobiological mechanisms underlying eating addictive-like behavior.

CONFERENCE XV

AGING, TDP 43 AGGREGATION AND NEURODEGENERATION

F. E. BARALLE

International Center for Genetic Engineering and Biotechnology, Padriciano 99 Trieste Italy

The aggregation of TDP-43 is the major distinguishing feature of most ALS cases. There is still a significant uncertainty in regards to many aspects concerning the nature of the aggregates and their functional consequences. For example, the biophysical characteristics of TDP-43 aggregates are still unclear, especially with regards to their possible amyloid composition that may be acquired under certain conditions. Furthermore, TDP-43 aggregates have recently been suggested to be responsible for the spreading of disease among neuronal cells in a prion like manner. All these aspects of TDP-43 aggregation need further definition, as new therapies could be directed towards them. At this point, therefore, it is essential to have a comprehensive catalog of the alterations of TDP 43 structure and function and identify those that are critical for the development of the disease. A better understanding of TDP 43 structure and interactions is needed and data on the N-Terminal Domain structure and C-Terminal domain intra and intermolecular interactions will be presented. In addition a focus is needed in the TDP-43self-regulation loop that could have a critical function on the development of the disease. Finally, ALS is a disease that occurs mostly during the fifth to the seventh decade of life. In this respect, we have previously shown that the onset of the locomotion defect in an ALS fly model coincides with an age-related 4-fold drop in TBPH levels (the Drosophila TDP43 orthologous), similar TDP 43 reduction with age was observed in mice brain. Thus, understanding the relationship between aging and TDP-43 production in cell culture, animal models, and human tissues might provide further clues to explain the age of disease onset.

CONFERENCE XVI

FROM FERTILIZATION TO THE IMMUNE SYSTEM

PATRICIA S. CUASNICU, Ph.D.
Institute of Biology and Experimental Medicine (IBYME-CONICET), Buenos Aires, Argentina

Fertilization is a key process involving a series of coordinated interactions between the male and female gametes. However, the mechanisms underlying this key process still remain to be elucidated. Our laboratory has been dedicated to underpin the molecular mechanisms involved in the acquisition of sperm fertilizing ability and gamete interaction using CRISP proteins as model molecules. Epididymal protein CRISP1, the first described member of the evolutionarily conserved CRISP (Cystein-Rich Secretory Protein) family, associates with the sperm surface during the maturation process that occurs while passing through the epididymis. Substantial evidence obtained using in vivo and in vitro approaches as well as knockout (KO) models shows that CRISP1 participates in both sperm-egg binding and gamete fusion through its interaction with egg-complementary sites. These observations can be extended to human as judged by the finding that the human CRISP1 also associates with sperm during maturation and participates in fertilization through binding sites in the human egg. More recent results reveal that CRISP1 is a novel regulator of CatSper, the principal sperm Ca(2+) channel essential for male fertility and that the protein is also expressed by the cumulus cells that surround the egg acting as a sperm chemoatractant during cumulus penetration. Thus, CRISP1 escorts both the male and female gamete and plays multiple roles during the fertilization process. In spite of its functional relevance, CRISP1 KO mice are fertile as are mice lacking CRISP4, another epididymal CRISP family member also involved in fertilization. Interestingly, recent evidence from our group shows that the simultaneous lack of both CRISP1 and CRISP4 (double KO) affects not only fertilization but also male fertility, confirming the existence of compensatory mechanisms between homologue proteins to ensure reproductive success. Moreover, the double KO males show severe defects in both the epididymal epithelium and luminal sperm as well as an abnormal presence of immune cells within the organ indicative of a disruption of the characteristic immune tolerance of the epididymis. Together, these observations confirm the relevance of CRISP proteins for fertilization and fertility and reveal novel inmunoregulatory roles for these proteins within the epididymis. We believe these results provide important information for a better mechanistic understanding of the maturation and fertilization processes that will contribute to future research on infertility and contraception.

CONFERENCE XVII

HETEROGENEITY OF THE HUMAN T CELL RESPONSE AGAINST MICROBES

FEDERICA SALLUSTO
Center of Medical Immunology, Institute for Research in Biomedicine, Università della Svizzera italiana, Bellinzona, Switzerland and Institute of Microbiology, ETH Zurich, Switzerland.

We study the human system to address fundamental questions in the context of the immune response to different classes of antigens, such as microbial pathogens, allergens or self-antigens, to gain insights into mechanisms that induce host protection or immune-mediated pathology. Our efforts towards human immunology have resulted in the development of high-throughput cell-based screening methods to analyze the human immune response and, in particular, the functional diversity and repertoire of human effector and memory T cells. The T cell library method allows the efficient and high-throughput interrogation of the human T cell repertoire without being limited by the complexity of the antigen, the HLA haplotype and the sample size. The method can be used to predict antigenicity and identify T cell epitopes to guide design of T cell vaccines or optimization of biologicals. When applied to the study of T cells in cancer and autoimmunity, it can provide tools for immunotherapy and insights as to the mechanisms of immune-mediated pathology. The T cell library method, together with high throughput TCR Vβ sequencing, which can analyze millions of T cell clonotypes in blood or tissues, mass spectrometry, and single-cell gene expression analysis, can provide a wealth of information that is expected to contribute to the progress in medical immunology research.

CONFERENCE XVIII

EVOLUTION AND HOST-SPECIFIC FUNCTIONS OF DENGUE VIRUS RNA STRUCTURES

Juan Carballeda, Luana de Borba, Horacio Pallarés, Franco Marsico, Claudia Filomatori, Sergio Villordo and ANDREA GAMARNIK
Fundación Instituto Leloir-CONICET, Buenos Aires, Argentina.

The Flavivirus genus include a large number of emerging and re-emerging human pathogens that are mainly transmitted by arthropods, including dengue, Zika, yellow fever and West Nile viruses. Dengue is the most prevalent arthropod-borne viral disease around the world. It is endemic in more than 100 countries, with about 390 million infections each year. In 2016, Latin America faced their worst dengue and Zika epidemics, without effective vaccines or antivirals to control infections.

Dengue virus contains a single stranded RNA genome, encoding at least ten viral proteins. We have previously identified the mechanism of viral genome amplification and defined conserved RNA structures that serve as promoters, enhancers and silencers of viral RNA synthesis. These elements are mainly located at the viral 5' and 3' untranslated regions (UTRs) and they communicate by conserved long-range RNA-RNA interactions. Interestingly, in the process of studying viral replication in mosquito and human cells, we identified a novel viral mechanism of host adaptation. This mechanism includes changes of viral RNA structures that play different roles during viral infection in each host. In this regard, replication of dengue virus in mosquito or human cells resulted in the selection of different viral populations with specific mutations in RNA structures in the viral 3'UTR. The selective pressure for this mutations was associated to the accumulation of different patterns of viral non-coding RNAs, directly involved in counteracting the cellular antiviral response. Using epidemic and pre-epidemic Zika isolates, similar patterns of non-coding RNAs were observed in mosquito and human infected cells, but they were different from those observed during dengue virus infections, indicating that distinct selective pressures act on the 3'UTR of these two related human pathogens.

Finally, by extrapolating our observations to other flaviviruses, we found RNA structure duplications at the 3'UTR of viruses that alternate between vertebrate and invertebrate hosts. Two pairs of duplicated structures were found in most mosquito-borne flaviviruses, and each of the duplicated element displayed a different function during viral replication. Interestingly, we found that the RNA duplication allowed to accommodate mutations beneficial in one host but deleterious in the other, providing robustness for viral replication in both cell types. These findings reveal a novel mechanism of viral host adaptation and provide new ideas for flavivirus 3'UTR evolution.

BUILDING AND MAINTAINING EPIGENETIC MEMORY: INSIGHTS FROM FLC

JULIA IRENE QÜESTA

(Department of Cell and Developmental Biology, John Innes Centre, Norwich Research Park, Norwich, United Kingdom)

Plants are sessile organisms and need to align their development to specific external cues from the different seasons. To be capable of inferring seasonal information, plants have evolved systems to sense environmental signals and also to 'remember' previous exposure to these signals. The floral repressor *FLORWERING LOCUS C* (*FLC*) has allowed the study of these mechanisms in *Arabidopsis thaliana*. *FLC* expression is repressed by prolonged cold exposure during winter in a process called vernalization. *FLC* repression is then epigenetically maintained until embryo development after flowering. Central to vernalization is the nucleation of a specialized Polycomb Repressive Complex 2 (PRC2) at an intragenic site within *FLC* to deposit the chromatin repressive mark H3K27me3. Our recent work has uncovered the role of the sequence-specific transcriptional repressor VAL1 in targeting Polycomb to *FLC* chromatin to initiate epigenetic silencing. In parallel, the cold-induced, long non-coding RNA *COOLAIR* facilitates *FLC* transcriptional shutdown by coordinating the switch between active and repressive chromatin states. Natural allelic variation at *FLC*, distinguished by polymorphisms in non-coding regions, influences the expression level and the rate of epigenetic silencing of the gene. Thus, modulation of chromatin-based mechanisms and non-coding RNA regulation, both crucial to vernalization, are likely to be generally involved in adaptation to changing environments.

ASCO LONG NONCODING RNA MODULATES ALTERNATIVE SPLICING PATTERNS IN *ARABIDOPSIS*

FEDERICO ARIEL

(Instituto de Agrobiotecnología del Litoral, CONICET, Universidad Nacional del Litoral, Santa Fe, Argentina)

Alternative splicing (AS) of pre-mRNAs represents a major mechanism boosting transcriptome and proteome complexity. In Arabidopsis, the long noncoding RNA *ALTERNATIVE SPLICING COMPETITOR* (lncRNA *ASCO*) was previously found to hijack the nuclear AS regulators NSRs to modulate AS patterns during root development. Here, we showed by RNA-seq that the deregulation of *ASCO* impacts the expression levels of stress and defense-related genes, including several members from the AP2/ERF and JAZ families of transcription factors. Furthermore, the knock-down of *ASCO* alters the AS pattern of certain stress-related pre-mRNAs, notably involved in senescence. Noteworthy, several pre-mRNAs alternatively spliced in *ASCO*-deregulated lines were not affected in the *nsra/b* double mutants, suggesting that *ASCO* also modulates alternative splicing in an NSR-independent manner. Therefore, we adapted a chromatin-related technique (called Chromatin Isolation by RNA Purification, ChIRP) to what we called nuclear Protein Isolation by RNA Purification (nPIRP) followed by Mass Spectrometry, in order to identify *ASCO*-associated protein complexes. Our nPIRP results suggest that *ASCO* is recognized *in vivo* by several specific splicing factors, as well as few stress- and phytohormone-related proteins. Altogether, our work indicates that *ASCO* modulates hormone and stress signaling via the regulation of alternative splicing of specific targets.

TMV SYSTEMIC MOVEMENT REQUIRES NEGATIVE MODULATION OF THE IMMUNE SYSTEM

SEBASTIÁN AZURMENDI

(Instituto Nacional de Tecnología Agropecuaria, Buenos Aires, Argentina)

An important aspect of plant-virus interaction, which remains insufficiently understood, is the way viruses dynamically modulate host immunity to achieve a successful infection. The plants have developed different mechanisms of immunity against the attack of pathogens. A well-characterized mechanism involves salicyl-

ic acid (SA), a hormone that has the ability to induce nuclear translocation of NPR1 (NON-EXPRESSOR OF PR GENES 1) and stimulate the transcription of a genes network involved in the immune response. Some pathogens have co-evolved developing strategies that allow them to silence the natural defense systems of plants. In Tobamoviruses, emerging evidences suggest that viral encoded proteins display a great variety of functions beyond the canonical roles required for virus structure and replication. Among them, the modulation of host immunity is arising as a relevant aspect required for the infection progression. We have shown that the Tobacco Mosaic Virus (TMV) capsid protein (CP) negatively modulates the SA-mediated defense pathway. We determined the role of DELLAs proteins in the modulation of signaling events during TMV infection. We demonstrated that during TMV infection, CP stabilizes DELLAs proteins and this stabilization results in the modulation of defense signaling pathway resulting in turn in a de-regulation of the gene network induced by SA-mediated immunity. Lastly and most importantly, we have demonstrated that this function of TMV CP, negative modulation of the plant immune system, is required for the systemic movement of the virus, therefore very important for the success of the infection.

MOLECULAR MECHANISMS OF PLANT FERTILIZATION

JORGE MUSCHIETTI

(Instituto de Investigaciones en Ingeniería Genética y Biología Molecular, CONICET, Buenos Aires, Argentina)

It has been described that most of the pollen proteins are synthetized during pollen development. However, there are reports about some pollen mRNAs that accumulate in dehydrated mature pollen grains but translated only after pollen germinates. Our hypothesis is that they are stored in cytoplasmic granules. We analyzed the cellular localization of the *SKS14* and *AT59* Arabidopsis mRNAs, which are orthologues of the tobacco *NTP303* and tomato *LAT59* pollen mRNAs respectively, by artificially labeling the transcripts with a MS2-GFP chimera. We developed a new MATLAB automated image analysis to identify and quantify the presence of cytoplasmic *SKS14* and *AT59* mRNA granules in mature pollen grains. These mRNA granules partially co-localized with VCS and DCP1, two processing bodies (PBs) proteins. In addition, we found that both VCS and DCP1 are necessary for the formation of *SKS14* and *AT59* mRNA granules. Finally, we found a temporal correlation between SKS14 protein accumulation and the disappearance of *SKS14* mRNA granules during pollen germination. These results would contribute on the understanding of how pollen translational regulation takes place in *Arabidopsis thaliana*. It remains to be elucidated whether these results can be extrapolated to other pollen genes.

SYMPOSIA II
B CELLS AND FOLLICULAR T HELPER CELL
Chairs: Eloisa Arana and Silvia Correa

MOLECULAR AND PHYSICAL MECHANISMS THAT ORCHESTRATE B CELL DEVELOPMENT

CORNELIS MURRE

(Division of Biological Sciences, University of California at San Diego, San Diego, California, USA)

It is now well established that the transcriptional regulators EBF1 and Bcl11b specify B and T cell fates, respectively. Here we show that in developing B- and T-lineage cells regulatory regions repositioned from the nuclear lamina to the transcriptionally permissive compartment. In early B cell progenitors the EBF1 and FOXO1 loci switch from the heterochromatic to the euchromatic compartment. Likewise we found that in early T cell progenitors the Bcl11b locus control region repositions from the nuclear lamina to the transcriptionally permissive compartment. In search for candidate factors that repositioned the EBF1 and Bcl11b control regions we identified ThymoD, an enhancer RNA (eRNA). We found that ThymoD-deficient mice are blocked at the DN2 cell stage. We found that ThymoD acts *in cis* to reposition the Bcl11b super-enhancer from the lamina to the nuclear interior. We demonstrate that ThymoD acts to promote CTCF and SMC3 occupancy across the ThymoD transcribed region to form a single loop domain that brings the Bcl11b super-enhancer and promoter within close spatial proximity. We will discuss related studies in the context of EBF1 and B cell development. These data indicate how eRNA-induced structural changes in nuclear architecture dictate with high precision enhancer-promoter communication to specify lymphoid identity

B CELLS AND FOLLICULAR T HELPER CELLS

JOSEPH E. CRAFT

(Yale University School of Medicine, New Haven, Connecticut, USA)

Initiation of a thymus-dependent humoral immune response requires interaction of activated B cells and follicular B helper T (Tfh) cells, a specialized subset of CD4 T helper (Th) cells. Differentiation of Tfh cells leads to their localization to B cell follicles and germinal centers (GC) of secondary lymphoid organs, with their expression of costimulatory proteins and secretion of cytokines promoting GC B cell proliferation, immunoglobulin gene hypermutation, and development of B cell memory and long-lived plasma cells. The transcriptional repressor Bcl6 acts cell autonomously to drive a Tfh cell development program, including upregulation of proteins necessary for function, with environmental signals promoting differentiation of these cells at the expense of other CD4 T subsets. Tfh cells undergo differentiation within the GC, enabling differential help to B cells, with affinity selection of the latter in part promoted by regulatory GC T cells. Therapeutically, blockade to Tfh-GC B interactions interrupts end-organ disease in the systemic autoimmune disease lupus, while resetting the Tfh cell phenotype toward normal homeostasis. Supported by NIH AR40072 and AR068662, and the Alliance for Lupus Research

GALECTIN-3 DEFICIENCY DRIVES LUPUS-LIKE DISEASE

ADRIANA GRUPPI

(Centro de Investigaciones en Bioquímica Clínica e Inmunología, CONICET, Facultad de Ciencias

Germinal centers (GC) are important sites for high-affinity and long-lived antibodies (Abs) induction and their overactivity causes autoimmunity. In our laboratory, we report a novel function by which Galectin-3 (Gal-3) is involved in the development of GC. Gal-3 KO mice exhibit a high frequency of GC B cells and T follicular helper cells that correlated with increased percentage of Ab-secreting cells and high concentrations of IgM, IgG2c, IgG3 and IFN-γ in serum. Likewise, Gal-3 KO mice develop a lupus-like disease, characterized by kidney infiltration and antinuclear Ab secretion. IFN-γ blockade in Gal-3 KO mice reduced GC formation, class-switch recombination, autoantibodies production and renal pathology, demonstrating that IFN-γ overproduction sustain lupus-like disease. Using chimeric mice with B cell-specific deficiency of Gal-3, we demonstrate that intrinsic Gal-3 signaling in B cells control spontaneous GC formation. Together, our data provide the first evidence that Gal-3 acts directly on B cells regulating GCs responses *via* IFN-γ.

AN EXPANDED FAMILY OF B CELL-HELPER T CELLS IN RHEUMATOID ARTHRITIS

DEEPAK A. RAO

(Harvard Medical School, Harvard University, Boston, Massachusetts, USA)

Determining the pathologic functions of T cells that infiltrate target tissues remains a central challenge in autoimmune diseases. Pathogenic CD4+ T cells within affected tissues may be identified by expression of markers of recent activation. Here, I discuss our studies using mass cytometry and multidimensional flow cytometry to interrogate T cell populations in synovial tissue and blood from patients with rheumatoid arthritis, a chronic immune-mediated arthritis that affects up to 1% of the population. Mass cytometric analysis of RA synovial tissue cells revealed a strikingly expanded population of PD-1^{hi} CXCR5^{-} CD4^{+} T cells, which constituted ~25% of synovial CD4^{+} T cells. Surprisingly, these cells are not exhausted, but instead highly express factors that confer the ability to help B cells, including IL-21, CXCL13, ICOS, SAP, and MAF. Like T follicular helper (Tfh) cells, PD-1^{hi} CXCR5^{-} T cells from synovium and blood induce plasma cell differentiation *in vitro* via IL-21. However, RNAseq transcriptomics robustly separate PD-1^{hi} CXCR5^{-} cells from Tfh cells, with altered expression of Bcl6 and Blimp-1 and unique expression of chemokine receptors that direct migration to inflamed sites, such as CCR2, CX3CR1, and CCR5, in PD-1^{hi} CXCR5- T cells. We suggest that PD-1^{hi} CXCR5^{-} CD4^{+} T cells represent a T peripheral helper (Tph) cell population, analogous to T follicular helper (Tfh) cells, that supports B cell responses in pathologically inflamed non-lymphoid tissues. Given their marked expansion in RA joints, these cells may be important in driving pathologic B cell responses and autoantibody production within the inflamed target tissue

SIMPOSIA III
NEW THERAPEUTIC APPROACHES FOR THE CONTROL OF CHAGAS DISEASE

CHAGAS DISEASE: CLINICAL EVIDENCE FOR ETIOLOGICAL TREATMENT

AND BIOMARKERS FOR ASSESSING RESPONSE

SERGIO SOSA ESTANI
(Drugs for Neglected Diseases Initiative, Buenos Aires, Argentina)

Specific anti-parasitic treatment for Chagas disease using benznidazole and nifurtimox is indicated in the following situations: a) All acute phase patients, including congenital transmission; b) Following reactivation of infection by immune suppression e.g. AIDS and transplantation; c) Patients up to 18 years of age with chronic disease; d) Women of childbearing age with *Trypanosoma cruzi* infection (with contraception during treatment). There is a relative consensus that drug treatment should generally be offered to adults aged 19–50 years without advanced Chagas heart disease, and is optional for those older than 50 years.

To date it is estimated that < 1% of infected patients are currently receiving treatment. This news, is a great challenge, and is opening a new pathway to be addressed to dramatically change access to the drug in endemic countries. Progress will be bolstered by the generation of new clinical evidence on the safety and efficacy of new antiparasitic treatment regimens, especially for adult patients with chronic Chagas disease. Several completed clinical trials have shown a clear trypanocide effect of benznidazole, and a non-sustained response to alternative drugs (TRAENA, BENEFIT, CHAGASAZOL, STOP CHAGAS, E1224). The search for new drugs for Chagas disease is actively underway, ongoing studies will add significantly to our knowledge of how to utilize existing drugs in the safest, most effective manner possible. A proof-of-concept Phase II study (BENDITA study-DNDi) underway in Bolivia is pursuing the evaluation of new regimens of benznidazole, as a monotherapy and in combination with fosravuconazole, for the treatment of adult patients with chronic indeterminate Chagas disease in order to improve tolerability, while maintaining or improving efficacy. Efficacy and safety analyses analysis of the first FEXI trial carried out in 2013 in Bolivia, interrupted due to safety and tolerability issues, suggested high efficacy rates of fexinidazole. These results led DNDi to design a new Phase IIA proof of concept trial to assess short regimens of Fexinidazole to be conducted in Spain.

Meanwhile, the Berenice project, an international initiative coordinated by Spain and with the participation of Argentina, Brazil, and Colombia, has launched the MULTIBENZ trial, which will evaluate lower doses of benznidazole. In Colombia, the CHICAMOCHA trial is assessing the efficacy of benznidazole and nifurtimox in adult patients in the chronic indeterminate stage of the disease. Another clinical study in Argentina is testing an intermittent regimen of standard doses of benznidazole to provide evidence on alternative regimen of this trypanocide. CHICO, a multicenter trial in Argentina, Bolivia and Colombia supported by Bayer, is evaluating the safety and efficacy of a new paediatric formulation of nifurtimox.

Ongoing clinical studies from DNDi and other groups are identifying and validating potential biological markers of therapeutic response in Chagas disease patients to support clinical development. DNDi is fostering and encouraging the testing of four biomarkers to assess response to treatment of Chagas through the Iberoamerican network NHEPACHA.

Continued progress on these various fronts will help ensure that diagnosis and treatment finally reaches the over 99% of people with Chagas disease who have thus far been neglected.

BISPHOSPHONATES A PROPOSAL FOR ANTIPARASITIC TREATMENT

ALICIA FUCHS
(Centro de Altos Estudios en Ciencias Humanas y de la Salud, Universidad Abierta Interamericana, Buenos Aires, Argentina)

Bisphosphonates (BP) are synthetic analogs of pyrophosphate in which two phosphates are connected through carbon instead oxygen. They classify in two groups due by the presence or not of a nitrogen, which favors BP intrinsic activity. The P-C-P are mainly responsible to bone binding, reduce hypercalcemia, and help bone mineralization acting on pH regulation and hydroxyapatite stability. BP are versatile drugs and depending of the target cells present different actions. The alendronate activity on NO· production, calcium deposition and alkaline phosphatase activity is target tissue depending. Moreover, the use of BP have been proposed against parasitological diseases. Studies are focus on its interferences on parasites incomplete metabolic pathways from which survival is depending, but others mechanisms of actions were proposed. The inhibition of farnesyl- geranyl diphosphate synthase, as substrate-like inhibitors, is essential for mevalonate synthesis and protein prenylation and important molecular- dynamics differences found between human or *Plasmodium* origin (Ricci et al, 2016), *T.brucei*, (Yang et al 2015) and *T.cruzi* (Huang et al, 2010). On the other hand, BP action on phosphate accumulation impaired its mobilization in *T.cruzi* acidocalcisome caused by the inhibition of translocating pyrophosphatase (Docampo and Moreno, 2008). In *Leshmania tarentolae* alkyl- alendronate decreased parasite growth *in vitro* (Christensen et al, 2016). In *T.brucei* the solanesyl disphophate synthase is inhibited by an experimental BP, 1-[(*n*-oct-1-yl-amino)ethyl] 1,1-bisphosphonic acid, which impaired ubiquinone 9 synthesis, causing ATP decrease (Lai et al, 2014). The decrease of ATP was also observed on EGPE, cell line, from bovine *E.granulosus*, as consequence of

five BP treatment *in vitro* but, only three of them caused decreased of cell growth. The most effective was etidronate (EHDP). Its deleterious effect was also related with total calcium accumulation, a fact not happening with the use of ibandronate (IB) or olpadronate (Fuchs et al, 2014). Diverse mechanism triggered by BP could regulate available Ca^{2+} suggested by the interaction observed on 1,3 -disphosphonates with L-type calcium channels inhibitors (Rossierq et al 1989). Our results showed that EHDP or amino- etidronate (N-EHDP) and IB (Gador SA, Buenos Aires) differentially modulate $[Ca^{2+}]_{cit}$ and phosphatase activity, depending of cell type, EGPE or HT29 (human colon adenocarcinoma). This could explained N-EHDP deleterious effect on EGPE and not on HT29 cells, at 30μM. Many new studies about anti parasitic effect of BP suggested that the improved of the effect should be achieve by the increasing the molecule lyposolubility (Yang et al, 2015). Other authors suggested that the presence of fluoride or sulfur increases the effect on apicomplexan parasites (Galaka et al, 2017). But, BP action on Helminths would depend of others factors acting on calcium uptake and on its intracellular distribution. Moreover, in spite of the many anti-parasitic possibilities, BP compounds effect *in vivo* would depend of its systemic distribution because their high affinity with the bone surfaces.

MODERN APPROACHES FOR THE DISCOVERY OF DRUGS AGAINST CHAGAS DISEASE

ALAN TALEVI

(Facultad de Ciencias Exactas, Universidad Nacional de La Plata, La Plata, Argentina)

According to the latest figure from the Panamerican Health Organization, there are more than 7 million people exposed to the disease in Argentina, and 1.5 million people infected (almost 4% of the total population). Whereas during the last years the "neglected disease" status of Chagas disease has fortunately started reverting, around 90% of the limited investment in research and development linked to Chagas comes from the public sector or non-for-profit organizations. Such scenario imposes the need of using rational approximations in the search of novel diagnostic and therapeutic tools.

Here, we describe different modern approaches towards the discovery of novel therapies against Chagas disease: *in silico* screening, high-throughput screening, drug design and systematic drug repurposing. Focusing on neglected conditions, the advantages and disadvantages of each one of them are discussed in terms of the technological and translational gaps. Some recent examples of successful applications are described.

NEW THERAPEUTIC STRATEGIES FOR THE TREATMENT OF CHAGAS DISEASE

CELINA LAMAS

(Instituto de Química de Rosario, CONICET, Rosario, Argentina)

Chagas disease or American tripanosomiasis is a neglected disease caused by the parasite Trypanosoma cruzi, which enters the body through broken skin and mucous membranes, producing several symptoms including fever, conjunctivitis and skin lesions. *Trypanosoma cruzi* is, found mostly, in blood-sucking triatomine insects (kissing bugs) which lives in the cracks of buildings and substandard houses. Although the vectorial transmission has been reduced Chagas' disease is still a major public health problem and one of the leading causes of morbidity, long-term disability and mortality in Latin America. Additionally to human morbidity and mortality, this parasitic infection place a substantial burden in poorer developing countries, increasing both the poverty and the vulnerability of those people.

Even though Chagas disease is transmitted primarily by insects the dissemination of this parasitic infection may occur by transfusion of blood from persons infected with *T. cruzi* and/or organ transplantation. Infected pregnant women may transmit *T. cruzi* to her newborn, resulting in congenital Chagas disease, also. It is worth mentioning that this neglected infection is becoming a serious concern that can have severe consequences for the public health, principally because of its potential to contaminate the blood transfusion supply as well as, its dissemination through surgical implantation of infected donor organs to patients in non-endemic areas including North America and Europe.

Although some progress focused in the process of drug discovery have been made in recent years, the significant cost of these projects discouraged pharmaceutical companies from investing in research and development programs against Chagas' disease, without assurances that they can make a return on their investment. As a consequence of it, up to these days, there are only two therapeutic agents applied to the treatment of Chagas' disease: Nifurtimox and Beznidazole. Despite of both active compounds are included in the WHO project "Better medicines for children", an effective chemotherapy for paediatric population infected with Chagas' disease is still lacking. Since both Nifurtimox and Benznidazole are formulated only into tablets, the pediatric population is treated by fractioning the solid dosage form in pieces according the body weight of each patient. This quite primitive and non-recommended therapy may cause undesirable side-effects due to the potential erroneous dosage. In addition, since paediatric patients include neonates (0-28 days), infant (1-12 months), and

children (1-12 years), another drawback for the availability of pediatric dosage forms is the particular dosing regime in each age group. In this context, the development of age-adapted dosage forms, in terms of easy administration and dose flexibility would be a remarkable advantage for improving the efficacy of Benznidazole. Thus, this presentation aims at demonstrating how pharmaceutical technology can assist in the development of new therapeutic platforms towards novel treatments using an old drug for Chagas disease.

SYMPOSIA IV
YOUNG INVESTIGATORS IN REPRODUCTION
Chairs: Clara Marín-Briggiler and Leandro Miranda

HORMONAL REGULATION OF INSECT REPRODUCTION

SHEILA ONS
(Centro Regional de Estudios Genómicos, CONICET, Universidad Nacional de La Plata, La Plata, Argentina)

Insects are the dominant terrestrial life form in Earth. They affect us directly either with harmful or beneficial consequences (vectors of diseases, crop damage/ pollinators, natural predators of pests, etc.). Their evolutionary success is due to particular strategies for development and reproduction, which have facilitated the colonization of a wide range of ecological niches. During post-embryonic development, insect larvae complete each molt by shedding the old cuticle, in order to emerge as the next developmental stage. This process culminates in adults able to produce mature gametes, and is perfectly regulated by endocrine networks composed of lipophilic hormones and neuropeptides. The crucial involvement of neuropeptides in development and reproduction suggests that these molecules could be promising targets for new-generation insecticides. Given their particular characteristics, neuropeptidergic-targeting insecticides will offer species-selectivity and environmental compatibility, with practical advantages compared to current neurotoxic insecticides.

The peptidergic signaling cascade regulating ecdysis at the end of each molt has been well studied for those insect species that undergo a complete metamorphosis (holometabolous) such as flies, moth, beetles, etc. The nodal components of this cascade are *Ecdysis Triggering Hormone* and *Eclosion Hormone*. However, the endocrine factors regulating ecdysis in Hemimetabolous (such as kissing bugs, cockroaches, etc) has not been characterized to date. Strikingly, even though adults do not molt, the hormones regulating ecdysis are expressed in this mature stage, as much in males as in females. This suggests pleiotropic physiological roles for ecdysis hormones. Recent reports indicate that the interrelationships of hormones occurring in juvenile stages to regulate molting and ecdysis is maintained in the adult stage to regulate gametogenesis and fecundity. Hence, the members of this hormonal network would be excellent candidates in the search for next-generation insect pest management strategies. In this context, our research group studies hormonal regulation in insects, focusing in the post-embryonic development and reproduction processes. Our results show for the first time that a particular family of neuropeptides called *Orcokinin* is a critical component of the regulatory network of ecdysis and reproduction in insects. When *Orcokinin* gene expression was silenced, phenotypes of arrested molting in kissing bugs and impaired reproduction in cockroaches were observed. Furthermore, we studied the components and interrelationships within this network in hemimetabolous, and found crucial differences with holometabolous. Our recent work suggests that Orcokinins could be excellent candidates as targets for novel insect pest management strategies.

KISSPEPTIN: IS IT THE GENE OF THE FIRST KISS IN FISH?

ALEJANDRO MECHALY
(Instituto Nacional de Investigación y Desarrollo Pesquero, CONICET, Mar del Plata, Argentina)

In mammals, the kisspeptin system, composed by the kisspeptin neuropeptide ligand and its receptor, *KISSR*, is involved in the regulation of onset of puberty and sexual maturation. In this group, kisspeptin is considered a gatekeeper of reproduction, since mutations in *KISS*/*KISSR* in several species blocked puberty. However its role on fish is not so clear. For example, recent knockout studies in zebrafish have demonstrated that spermatogenesis and folliculogenesis, and subsequently the ability to reproduce are not impaired. In teleost fish, genome duplication made the system more complex, with two kisspeptin genes (*kiss1 and kiss2*) and three receptors (*kissr1, kissr2 and kissr3*). The genome duplications events and the enormous diversity of reproductive strategies make teleost fish interesting models to study the involvement of kisspeptin in reproduction. Also, by using bioinformatics tools, we reported the gene structure organization of two kisspeptin receptors (*kissr2* and *kissr3*) in pejerrey fish. Genomic analysis revealed their gene organization and the presence of alternative

spliced variants of the kisspeptin receptor in several fish species. Modeling and structural analysis of Kissr2 and Kissr3 revealed that truncation of the proteins may lead to non-functional proteins, as the structural elements missing are fundamental for receptor function. These findings may contribute to a better understanding of the many physiological functions suspected to be mediated kiss/kissr signaling pathway. Surprisingly, no evidence of alternative splicing was detected in mammals, suggesting that this mechanism is probably unique for fish. Other differences between fish and mammalian models are in relation with neuroendocrinological regulation of food intake. Although numerous experimental studies in fish suggest a role in reproduction for this system, little is known about its participation in food intake control. In that sense, evidences of a possible link between energy balance and reproduction mediated by kisspeptin signaling in non-mammalian vertebrates were discovered in some fish species such as the Senegalese sole and pejerrey. It is generally believed that fasting inhibits the reproductive axis and kisspeptin gene expression in the mammalian hypothalamus; however, the opposite effect was observed in fish, probably due to the variation of life strategies across different fish species. Thus, the aim of this presentation is to give an up to date review of the kisspeptin system in vertebrates with special emphasis in teleost fish with a particular view of their role in reproduction and others novel functions. Nevertheless, there are many important questions that need to be addressed in future studies of the kisspeptin system in fish and the new genomics technologies, through the next-generation sequencing (NGS), can provide some answers about the roles of alternative isoforms or role of kisspeptin system genes under different nutritional conditions or other external factors such as temperature or photoperiod.

CYCLOOXYGENASE AND PROSTAGLANDINS IN TESTICULAR PHYSIOPATHOLOGY

EUGENIA MATZKIN

(Instituto de Biología y Medicina Experimental, CONICET, Buenos Aires, Argentina)

Prostaglandins (PGs) are bioactive lipid substances derived from arachidonic acid. They are produced by almost all nucleated cells and can, therefore, be found in most tissues. PGs are generated in a complex biosynthetic pathway in which cyclo-oxygenase (COX) is the rate-limiting enzyme. Two isoforms of this enzyme have been described: COX-1 and COX-2. They are encoded by two separate genes and exhibit distinct cell-specific expression, subcellular localization and regulation. While COX-1, commonly known as the constitutive isoform, seems to mediate housekeeping functions, COX-2, the inducible isoform, seems to be expressed in response to varying stimuli such as growth factors and cytokines.

Given their ubiquitous nature, PGs are involved in diverse physiological and pathological processes, including regulation of inflammatory and immune responses, cell growth, vascular tone, angiogenesis and tumorigenesis. Regarding reproductive function, interesting findings were described in the early 1990's using mouse models with targeted disruption of COX. While COX/PGs were found to be important regulators of female reproductive function (ovulation, uterine receptivity, implantation and parturition), fertility was not affected in male mice with COX deficiency, thus suggesting that PGs may not be critical for male reproductive function. However, this view has recently been challenged by novel observations stating essential roles for PGs in testicular physio-pathology. We have described a COX-2/PG system in the two key somatic cell types of the testis: Leydig and Sertoli cells. Our studies have provided insights into how several hormones and cytokines (i.e., follicle stimulating hormone, prolactin, testosterone and IL-1β) modulate COX-2 expression and PG production in these somatic cells. Studies performed mainly in rodents indicate that some PGs (i.e., PGD2 and PGF2α) modulate androgen production in Leydig cells, while 15d-PGJ2 regulates glucose transport in Sertoli cells and, consequently, spermatogenic efficiency. Furthermore, using mouse models with delayed (Ames dwarf and growth hormone releasing hormone-knockout mice) or accelerated (growth hormone-transgenic mice) aging we have shown an inverse association between longevity and testicular COX2/PGD2 system. Relevant to male (in)fertility, we have reported that although COX-2 is not detected in human testes with no evident morphological changes or abnormalities, it is expressed in testicular biopsies of men with impaired spermatogenesis and infertility. In addition to its expression in Leydig and Sertoli cells, COX-2 has been detected in the seminiferous tubule wall, and in testicular macrophages and mast cells of infertile patients. These observations stress the possible relevance of PGs in testicular inflammation associated with idiopathic infertility.

Collectively, these data indicate that the COX-2/PG system plays crucial roles not only in testicular physiology (i.e., steroidogenesis, spermatogenesis, reproductive aging), but also in the pathogenesis or maintenance of infertility status in the male gonad. Therefore, the study of COX and PG actions emerges as a promising field of research with potential impact on male fertility. Further advances in the knowledge of the role played by COX, PGs, and their receptors in the human testis, as well as future studies concerning the impact of drugs targeting COX/PGs at the testicular level, could lead to new therapeutic approaches in idiopathic male infertility.

PARTICIPATION OF LIPID MEDIATORS IN HUMAN TROPHOBLAST MIGRATION DURING

THE FIRST TRIMESTER. ROLE OF CAMP

MICAELA SORDELLI
(Centro de Estudios Farmacológicos y Botánicos, CONICET, Buenos Aires, Argentina)

An intricate molecular dialogue between trophoblast and uterus initiates the process of implantation, by which the embryo attaches to the lining of the uterus. After implantation, trophoblast cells begin a proliferative, migrating and invasive process infiltrating the decidua, remodeling uterine vasculature and connecting the mother blood stream with the fetus. These events are accomplished by molecular and cellular interactions controlled by the maternal-fetal interface microenvironment and may fail in certain obstetric complications such as preeclampsia, intrauterine growth restriction and implantation failure. Several years ago, it has been observed that there is a change in the lipid composition at the luminal epithelium adjacent to the area where the blastocyst is attached. This change is interpreted as a mobilization of precursors for the synthesis of lipid molecules that participate in angiogenesis and in the transformation of endometrial fibroblasts into decidual cells. Hence, novel insights with respect to roles played by the participation of lipids in the establishment of pregnancy have sparked a renewed interest in understanding them no longer as simple structural components of the membranes but as reproductive bioactive mediators. In this sense, lysophosphatidic acid (LPA) and prostaglandins play a major role in embryo implantation. LPA has pleiotropic functions by binding to six G-protein coupled receptors. Prostaglandins have a pivotal role in decidualization and vascularization, two main processes during trophoblast migration and invasion. We have previously reported that LPA augments the production of cyclooxygenase-2 derived prostaglandin E2 in the rat uterus during the window of implantation. Trophoblast cells are the main source of LPA in human first trimester, suggesting that LPA actively participates in trophoblast functions. Defects in trophoblast migration and invasion are particularly vulnerable to failure during embryo implantation resulting in pregnancy complications. Therefore, we aimed to investigate the role of LPA on human first trimester trophoblast´s functions and its interaction with prostaglandin E2. To achieve our experiments, we use a well-known immortalized human first trimester trophoblast cell line HTR-8/SVneo. We design a pharmacological strategy using selective and broad range LPA receptors antagonists and cyclooxygenase inhibitors. First, we characterize the mRNA expression of LPA receptors and the enzyme Lysophospholipase-D, the main enzyme involved in LPA synthesis and its principal source during gestation are the placental trophoblast. We observed that LPA stimulates both invasion and migration through LPA1-LPA4 receptors ($p<0.05$, but does not modify proliferation. Then we found that cyclooxygenase-2 derived prostaglandins mediate the increase triggered by LPA on trophoblasts cells since cyclooxygenase inhibitors diminish LPA increased migration ($p<0.05$). Interestingly, LPA stimulates prostaglandin E2 production ($p<0.05$) and immunocytochemistry experiments suggest that trophoblast cells stain positive for cyclooxygenase-1 and 2 in the cytoplasm and plasma membrane. Overall, these results demonstrate that LPA and prostaglandin E2 perform primordial functions at the maternal-fetal interface modulating trophoblast invasion and migration by a prostaglandinmediated mechanism triggered via LPA. Our findings contribute to better understand the significance of LPA signaling in the trophoblast behavior that lead to a successful pregnancy

SIMPOSIA V
INFLAMMATION AND AUTOIMMUNITY
Chairs: Analía Trevani and Gerardo Mirkin

LNCRNAS AND INFLAMMATION

JORGE HENAO-MEJÍA
(Perelman School of Medicine, University of Pennsylvania, Philadelphia, Pennsylvania, USA)

Epigenetic modifications induced by extracellular cues enable cells to rapidly adapt to changes in their environment. Long non-coding RNAs (lncRNAs) are now considered key controllers of epigenetically regulated gene expression. Notably, emerging evidence indicates that lncRNAs play a critical role in integrating extracellular inputs with epigenetic modification pathways to promote changes in gene expression programs. Given the tight regulation that is required to maintain innate immune cells on check and prevent the development immunopathology, we propose that highly inflammatory cells specifically express lncRNAs that are required to finely tune these cells to their environment, to both promote anti-pathogen immunity and prevent immunopathology. In here, we combined a novel bioinformatic workflow with the CRISPR/Cas9 system to provide evidence that rapid and local regulation of gene expression by lncRNAs in response to extracellular cues is a powerful and potentially generalizable mechanism through which optimal immune cell homeostasis is achieved.

NEUTROPHIL DAMAGE AND HYPERCITRULLINATION IN RHEUMATOID ARTHRITIS

FELIPE ANDRADE
(School of Medicine, Johns Hopkins University, Baltimore, Maryland, USA)

Rheumatoid arthritis (RA) is a chronic autoimmune disease, characterized by inflammatory infiltration of the synovial membrane, destruction of articular cartilage and erosion of bone. While the etiology of RA is still unknown, there has been enormous progress in this area, largely fueled by the discovery that citrullinated proteins are the major targets of autoantibodies in RA. Protein citrullination (or deimination) is the enzymatic conversion of peptidyl-arginine residues to peptidyl-citrulline and is mediated by the family of calcium-dependent peptidylarginine deiminases (PADs), which includes five PAD isoforms (PAD1 to PAD4 and PAD6). The finding that patients with RA have antibodies against citrullinated proteins (known as ACPAs) has suggested the possibility that the disease might be driven by dysregulated citrullination. Yet, the mechanisms that dysregulate and sustain citrullination in RA are not fully understood. In recent studies, we identified that membranolytic damage in neutrophils induced by host and bacterial pore-forming proteins (PFPs) are potent inducers of cellular hypercitrullination and the production of citrullinated autoantigens targeted in RA. PFPs serve as defense mechanisms both in pathogenic bacteria to kill host cells in order to promote colonization and spread, and in vertebrates (e.g., perforin and the complement membrane attack complex, MAC) to kill bacteria and infected cells to limit infections. PFPs create pores on the surface of cells, which initiate membrane destabilization, influx of extracellular calcium, and ultimately cell death. Neutrophils are innate immune cells which are abundant in PAD enzymes. Since the PAD enzymes are activated with calcium, the abrupt exposure to high amounts of calcium during PFP-induced neutrophil death overactivates these enzymes, generating a massive production of citrullinated autoantigens. During this process, citrullinated proteins are released into the extracellular space in a process that is consistent with cell death by leukotoxic hypercitrullination (LTH), a mechanism that distinguishes toxin-induced cytolytic changes from NETosis. We proposed that in RA, bacterial-induced LTH is a potential source of autoantigens that initiate the lack of tolerance to citrullinated proteins. In this regard, we recently identified the periodontal pathogen *Aggregatibacter actinomycetemcomitans* (*Aa*) as a potent induced of LTH and a candidate bacterial trigger for RA. Host PFPs, such as perforin and MAC, appear to be major drivers that sustain LTH in the RA joint. Membranolytic damage and cellular hypercitrullination induced by bacterial and host PFPs may represent a unifying mechanism that initiates and sustains autoantigen production at various disease sites in RA.

OXIDATIVE STRESS DRIVES INNATE-ADAPTIVE IMMUNE CROSSTALK IN HUMAN CHAGAS DISEASE

MARÍA DEL PILAR AOKI
(Centro de Investigaciones en Bioquímica Clínica e Inmunología, CONICET; Facultad de Ciencias Químicas, Universidad Nacional de Córdoba, Córdoba, Argentina)

Reactive oxygen and nitrogen species, generated by phagocytic cells, are important microbicidal agents but also, they are involved in lymphocyte unresponsiveness. Within metabolites that mediate many of the biological effects attributed to nitric oxide are peroxynitrites, which induce the nitration of immune cells. Particularly, nitration of tyrosines in the surface of CD8+ T cells results in the inability of these cells to bind MHC and, in consequence, to mount a specific cytotoxic response. Thus, although lymphocytes are in all likelihood the instigators of chronic inflammatory disease, activated monocytes are well equipped to cause its dysfunction. In consequence, the study of the crosstalk between T cell and myeloid cell compartments would be important to clarify the immunopathology of chronic inflammation. The major infectious heart disease in the world is represented by American trypanosomiasis, or Chagas disease, which is the result of human infection by the protozoan parasite *Trypanosoma cruzi (T. cruzi)*. Following infection, both innate and adaptive immune systems induce the clearance of circulating parasites. However, despite infection control, most patients progress to a chronic phase and around 30% of infected people develop chronic cardiomyopathy usually after decades of asymptomatic infection. We found a higher frequency of hypoxia inducible factor (HIF)-1α+ and nitric oxide-producing monocytes in asymptomatic patients with long-term *T. cruzi* infection. The presence of inflammatory monocytes promotes surface-nitration of circulating CD8+ T cell. Underlining the physiological relevance of our findings, increased tyrosine nitration was associated with impaired effector functions of CD8+ T cells in chronic Chagas patients. These findings have important clinical implications, considering that CD8+ T cell-mediated protective immunity has become a center of intense research to find control measures that could be used to produce effective therapeutic vaccines.

UNDERSTANDING THE COMPLEX IMMUNOPATHOGENESIS OF *TRYPANOSOMA CRUZI* INFECTION: THE ROAD TO CLINICAL MANAGEMENT OF CHAGAS DISEASE

MANUEL FRESNO

(Centro de Biología Molecular Severo Ochoa, Universidad Autónoma de Madrid, Madrid, Spain)

Chagas disease (CD) is a complex disease, presenting various clinical outcomes such as spontaneous healing, asymptomatic infection, cardiac, visceral, or cardio-visceral forms. Furthermore, the etiologic agent of CD, the parasite *Trypanosoma cruzi*, exhibits high genetic diversity, proposed to be associated to the diverse clinical outcomes of CD. Despite the discovery of this disease more than 200 years ago, still there are many controversies about its pathogenesis Understanding the pathogenic mechanism may have deep implications in the clinical management of this disease. Parasite replication, inflammation and autoimmunity have been described as responsible mechanisms.

To address this issue, we have employed a murine model system by using 2 different mice strains, Balb/c and C57B6. We also used multiple *T. cruzi* strains, including at least a representative of the 6 different main lineages (DTUs) to infect mice and analyzing the course of infection in the acute and chronic phase. Organ and systemic immune responses, parasite tropism and replication in several tissues, histopathological damages, metabolic changes, etc, were analyzed. Data reveal important differences between the genetic background of the host and of the strains. We found that the parasite genetic background impacts parasite tropism, host responses, and clinical presentations of CD. Thus, systemic and Local Immune Response differs among strain. Adaptative Th17, Th1, Th2 and CD8+ T cytotoxic immune responses, as well as immunosuppressive responses (Treg and Myeloid Derived Suppressor Cells) are induced differentially and may play a different, even opposite, role on the course of the disease depending on the genetic of the host and parasite. Interestingly, in chronic phase, cardiac damage can exist without detectable parasite load whereas chronic intestinal damage was always linked to parasite burden. Moreover, organ damage may decrease or increase in the chronic phase depending of the tissue analyzed and the infecting *T. cruzi* strain.

Our results show a great variability at the level of tropism, organ damage, local and systemic immune responses, illustrating the high diversity of the CD an d more importantly warning against simplification of the problem of this disease. However, combinations of some pathophysiological parameters using a systems biology approach allowed to group parasite strains, while other combinations permitted to gather individuals with respect to the type or level of clinical damage they underwent. This diagnostic significance of some infection factors underlines their importance as markers and/or determinants of the pathophysiology of CD. Finally, some parameters were studied in CD patients, showing that they can be used as biomarkers of clinical manifestations.

AUTOPHAGY COOPERATES IN THE DEGRADATION OF KEY MOLECULAR PLAYERS IN ALZHEIMER'S DISEASE

PATRICIA BURGOS

(Universidad Austral de Chile, Valdivia, Chile; Centro de Biología Celular y Biomedicina, Universidad San Sebastián, Santiago, Chile; Center for Aging and Regeneration, Pontificia Universidad Católica de Chile, Santiago, Chile)

Department of Physiology, School of Medicine, Universidad Austral de Chile, Valdivia, Chile; Centro de Biología Celular y Biomedicina, Universidad San Sebastián, Santiago, Chile; Center for Aging and Regeneration (CARE), Facultad de Ciencias Biológicas, Pontificia Universidad Católica de Chile, Santiago, Chile

Brain regions affected by Alzheimer's disease display well-recognized early neuropathological features in the endo-lysosomal and autophagy systems of neurons, including enlargement of endosomal compartments, progressive accumulation of autophagic vacuoles, and lysosomal dysfunction. Although the primary causes of these disturbances are poorly understood, a growing body of evidence suggests that the amyloid precursor protein (APP) intracellular C-terminal fragment-β (C99), generated by cleavage of APP by BACE1, is the earliest initiator of synaptic plasticity and long-term memory impairment. Herein we show that autophagosomes are key organelles for maintaining intracellular C99 and BACE1 levels, strongly indicating a direct relationship between the endo-lysosomal protein degradation pathway and autophagy.

FUSEXINS, A FAMILY OF SEXUAL, SOMATIC AND VIRAL CELL FUSION PROTEINS

PABLO S. AGUILAR

(Instituto de Investigaciones Biotecnológicas "Dr. Rodolfo A. Ugalde", CONICET, Universidad Nacional de San Martín, Buenos Aires, Argentina)

Cell-cell fusion is essential for fertilization and sculpting of bones, muscles, epidermis and placenta in different or-

ganisms. However, the proteins that mediate membrane fusion between cells have not yet been well-characterized and in some cases are still unknown. HAP2(GCS1) are membrane glycoproteins essential for gamete fusion in plants, *Chlamydomonas*, *Plasmodium*, *Tetrahymena*, and *Dictyostelium*. To investigate whether HAP2 is not only essential but also sufficient for cell-cell fusion, we expressed the *Arabidopsis* sperm HAP2 in cultured baby hamster kidney cells that normally do not fuse. We found that HAP2 expression in these heterologous cells results in the formation of multinucleate cells by cell-to-cell fusion [1]. Genetic and cell biological analyses showed that HAP2 has to be present in only one of the fusion partners (usually the male gamete) [2,3]. However, we found that when expressed in mammalian cells, *Arabidopsis* HAP2 is sufficient to fuse them only when expressed in both fusing cells [1]. Thus, HAP2-mediated plasma membrane merger occurs via a bilateral zippering mechanism reminiscent to intracellular fusions mediated by SNAREs, atlastins and mitofusins. Furthermore, expression of HAP2 on the surface of pseudotyped vesicular stomatitis virus results in virus-cell fusion only to cells that also express HAP2. Thus, we propose that, in addition to sperm HAP2, a HAP2-like protein is needed in the egg for gamete fusion. Structural modeling of the HAP2 protein family predicts that it is homologous to class II viral fusion proteins (e.g. Zika, rubella and dengue) and the somatic cell fusogen EFF-1 from *C. elegans* [1-3]. Moreover, the recently solved crystal structure of *Chlamydomonas'* HAP2 demonstrates structural homology with EFF-1 and class II viral fusion proteins [3]. We name this superfamily FUSEXINS: FUSion proteins essential for sexual reproduction and EXoplasmic merger of plasma membranes. Fusexins mediate enveloped virus entry into cells, sexual reproduction, and somatic cell fusion. These proteins share the same structure and function but use distinct mechanisms to merge membranes. We hypothesize that modern fusexins have existed since the dawn of eukaryotic cells.

REGULATION OF EXTRACELLULAR ATP IN HEALTH AND DISEASE

PABLO J. SCHWARZBAUM

(Instituto de Química y Fisico-Química Biológicas "Prof. Alejandro C. Paladini", CONICET; Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, Argentina)

Human red blood cells (rbcs) can release ATP when exposed to adrenergic stimulation, mechanical deformation, cell adhesion, blood flow turbulence, hypoxia and acidosis or, unspecifically, under conditions promoting hemolysis.

A reduction of ATP release has been associated with type II diabetes and cystic fibrosis, while rbcs infection with *Plasmodium falciparum* correlated with activated ATP release. Both, in physiological and pathological conditions, the resulting extracellular ATP (ATPe), and its metabolic products, can activate purinergic receptors which mediate a wide variety of local and systemic responses, such as changes in cell volume or intravascular pressure.

Irrespective of the nature of the stimuli, kinetics of ATPe accumulation depends not only on ATP exit, but also on ATPe hydrolysis by nucleotidases. This is because ATPe concentration can be downregulated by ectonucleotidases of intact rbcs, or by intracellular nucleotidases released to the extracellular space under hemolysis.

Candidate conduits for regulated –non lytic- ATP release include several anionic channels and pore forming proteins. In addition, bacterial toxins such as alpha hemolysin (HlyA) were shown to activate ATP exit of rbcs, presumably by forming pores through which the nucleotide transverses the plasma membrane.

HlyA is an exotoxin secreted by uropathogenic strains of *Escherichia coli*, causing lysis of several mammalian cells, including human rbcs. *In vivo* HlyA has been associated with urinary tract infections and septicemia. HlyA is secreted by bacteria in the intravascular milieu, where it can bind to rbcs and other cells.

During this talk we will analyze ATPe regulation of rbcs exposed to HlyA and analogs.

We made a quantitative estimate of ATPe kinetics, together with a description of the main processes controlling HlyA-dependent ATP regulation of rbcs.

Our results show that, in rbcs:

- Exposure to HlyA produced a nonlinear and biphasic increment of ATPe, caused by simultaneous lytic and non lytic ATP release. The [ATPe] increase showed an acute phase, mainly driven by non lytic ATP release, and a late phase that is mostly dependent on lytic ATP release and ATPe hydrolysis by nucleotidases.
- Moreover, HlyA led to slight swelling and increased sphericity, which was in part responsible for the observed activation of ATP release.
- Both proHlya, the unacylated precursor of HlyA and HlyA-GF(-), an HlyA mutant lacking the segment capable of binding to rbcs glycophorin, showed little or negligible ATP exit.
- Blockage of P2X receptors led to significant reduction of HlyA induced hemolysis, causing downregulation of ATPe kinetics.

Several experiments are under way to test other processes potentially affecting ATPe regulation of HlyA treated rbcs. Among these are aggregability and deformability of rbcs, intravascular pressure, and rbcs adhesion to endothelial cells.

With grants from UBACYT (20020130100027BA), PICT 2014-0327, CONICET (PIP0459) y ECOS Sud (Francia)-MINCYT(Argentina) A15S01, PDTS-CIN 193.

MOLECULAR CROSS-TALK IN OUTER RETINA; ANGIOCRINE FACTORS SECRETED BY CHOROIDAL ENDOTHELIAL CELLS CONTROL OUTER RETINA-BLOOD BARRIER AND CHOROID INFLAMMATORY RESPONSE

ENRIQUE RODRIGUEZ BOULAN

(Margaret Dyson Vision Research Institute, Weill Cornell Medicine, New York, USA)

The outer retina is composed of a layer of rods and cones, collectively called photoreceptors (PR), closely apposed to a layer of pigmented epithelial cells, the Retinal Pigment Epithelium (RPE). Light is transduced by photoreceptors into electric impulses that travel to specialized neurons in the inner retina and from there to the brain. PR function is intimately dependent on key support functions performed by the RPE, including its key role as a selective Outer Retina-Blood Barrier (ORBB) between the retina and the underlying choroid circulation. The RPE is separated from the underlying choroid capillaries by Bruch's membrane (BM), an elastin- and collagen-rich basement membrane produced by RPE and choroid. Recently, it has become clear that endothelial cells (ECs) are tissue-specific and constitute instructive niches that secrete key angiocrine factors that promote parenchymal cell differentiation and tissue regeneration (Rafii et al, Nature, 2016). To explore this hypothesis in the eye, we purified ECs from developing and adult mouse choroidal vasculature, as well as from neural retina, liver, lung and heart. In a recent study (Benedicto et al, Nature Communications, 2017), we showed that adult choroid ECs display a unique transcriptome enriched in extracellular matrix-related transcripts and regulate RPE barrier function through angiocrine factors. Moreover, we showed that EC-secreted factors control BM assembly, which in turn is sensed by RPE integrin receptors and transduced via small GTPases into changes in the molecular composition and function of RPE tight junctions. Additional studies uncovered a novel Indian Hedgehog (IHH)-dependent pathway in the choroid that may play an important role in immune regulation of the retina. The significance of our findings in the context of Age Related Macular Degeneration, a major retinal blinding disease, will be discussed. Supported by NIH grants, Research to Prevent Blindness, Dyson Foundation and Starr Foundation.

THE HISTAMINE H_4 RECEPTOR: TRANSLATION OF PRECLINICAL MODELS TO CLINICAL EFFICACY

ROBIN L. THURMOND

Janssen Research & Development, LLC San Diego, CA USA

Histamine exerts its physiological activities via the activation of four receptors. All of these receptors have been considered targets for the treatment of a variety of diseases, with drugs acting at histamine H_1 and H_2 receptor being available for many years. Ligands for the most recently discovered receptor, the histamine H_4 receptor, have just started to be tested in the clinic. The H_4 receptor mediates chemotaxis and cytokine release of mast cells, eosinophils, monocytes, dendritic cells and T cells. In addition, histamine released from mast cells or from other cell types can influence T cell polarization via activation of the H_4 receptor. The receptor also mediates T cell activity in vivo and has a proinflammatory effect not only in models of the innate immune response, but also in models of asthma, dermatitis and arthritis. Extensive medicinal chemistry and pharmacology efforts have led to the development of modulators with excellent potency and selectivity for the H_4 receptor. Two of these molecules, toreforant and JNJ-39758979, have entered human testing. These compounds have been shown to be anti-inflammatory in mouse models of dermatitis, asthma and arthritis. In a mouse model of atopic dermatitis H_4 receptor antagonists reduced skin edema, inflammation, mast cell and eosinophil infiltration. This was accompanied by a reduction in the levels of several cytokines and chemokines in the skin. In addition to anti-inflammatory effects there was also significantly inhibited the pruritus exhibited in the model. These findings have translated into clinical efficacy. A study assessed the safety and efficacy of JNJ-39758979 in patients with moderate atopic dermatitis. Numerical improvements were observed in the Eczema Area and Severity Index score at week 6 compared to baseline, but these changes did not reach statistical significance. Nominally statistically significant

symptomatic improvements were seen in patient-reported itch severity and duration. In addition to atopic dermatitis, H_4 receptor antagonists also have effects in preclinical eosinophilic asthma models. Treatment with H_4 receptor antagonists improved lung function, reduced lung inflammation and eosinophilia as well as reduced inflammatory cytokines in the lung. In the clinic it has been shown that JNJ-39758979 improved lung function in mild to moderate eosinophilic asthma patients. H_4 receptors are also involved in autoimmune diseases and H_4 receptor antagonists reduce symptoms in mouse arthritis models. Once again the preclinical results appear to predict efficacy in human diseases as an early study with the H_4 receptor antagonist toreforant showed a reduction in signs and symptom in patients with rheumatoid arthritis. Although there is still much work to be done, there has been much progress in using preclinical models to understand the physiological role of the H_4 receptor and the translation of these findings into early success in clinical studies.

CYSTIC FIBROSIS FROM LABORATORY TO CLINIC

MADELEINE ENNIS

Centre for Experimental Medicine, The Wellcome-Wolfson Building, School of Medicine, Dentistry and Biomedical Sciences, Queens University Belfast, 97 Lisburn Road, Belfast, BT9 7BL UK

Email: m.ennis@qub.ac.uk

Cystic Fibrosis (CF) is an autosomal recessive disorder affecting 1 in every 2500 live births in the UK. Although most common in Caucasian individuals of Northern European descent it can affect any ethnicity. The underlying pathology of CF is a mutation in the gene coding for the cystic fibrosis transmembrane conductance regulator (CFTR), leading to altered expression and function of this protein. Although many body systems are affected including digestive, reproductive and pancreatic systems; pulmonary disease, characterized by infective exacerbations, bronchiectasis and increasing airway insufficiency is the most serious manifestation of the disease process, currently responsible for over 80% of CF deaths. This first part of the talk will provide a background to the pathophysiology of the disease.

The second part of the talk will concentrate on laboratory methods to investigate airways disease in CF. Data will be presented examining cell lines and isolated primary airway epithelial cells. The prolonged and heightened inflammatory response seen in CF is, in part, mediated by a lack of intrinsic down-regulation of the proinflammatory NF-κB pathway. A20 [TNFα-induced protein 3 (TNFAIP3)] is a central negative regulator of NF-κB activation. We found that naturally occurring plant diterpenes such as gibberellin could induce A20 and had anti-inflammatory effects in vitro. Using gene expression connectivity mapping we were able to identify existing drugs that could induce A20 expression.

The final part of the talk will examine how using isolated primary airway epithelial cells were used to test novel drugs used to correct the defect in CFTR i.e. to increase the delivery and amount of functional CFTR protein at the cell surface or to potentiate CFTR i.e. to increase channel activity of CFTR protein located at the cell surface. Data from clinical trials with the CFTR corrector, Lumacaftor; the potentiating drug, Ivacaftor and the combined treatment will be presented.

This talk will highlight the importance of close collaboration between basic and clinical scientists to help alleviate a chronic condition.

IMMUNOPHARMACOLOGICAL CHALLENGES AND OPPORTUNITIES IN MODERN TARGETED THERAPEUTICS

KATERINA TILIGADA

Department of Pharmacology, Medical School, National & Kapodistrian Univestity of Athens, M. Asias 75, 11527 Athens, Greece – Email: aityliga@med.uoa.gr

Drugs targeting immune pathways have been exploited in the treatment of inflammatory, allergic and autoimmune disorders for more than 50 years. Over the last two decades, the enormous interest of scientists in the interface between pharmacology and immunology and the rapid expansion of biotechnology made available increasingly sophisticated clinically relevant immunopharmacological interventions that are largely tailor-made to specific patient populations. The currently growing field of Immunopharmacology builds on the rapid progress in immunology, and is paralleled by the growing number of new classes of molecular-targeted therapies. The related challenges and opportunities are reflected by the establishment of *ImmuPhar*, the new Immunopharmacology section of the International Union of Pharmacology of Basic and Clinical Pharmacology (IUPHAR) (www.iuphar.org/index.php/sections-subcoms/immunopharmacology), and *GtoImmuPdb*, the Guide to Immunopharmacology database (www.guidetoimmunopharmacology.org).

The novel products include small molecules and biological agents. Compared to conventional pharmacotherapy, they are designed to interact with specific targets and to minimize or even eliminate adverse effects. This

cutting-edge biomedical research promises to offer effective therapeutic approaches for an expanding range of unmet medical needs. Among them, the emergence of therapeutic monoclonal antibodies (mAbs) revolutionized the options for pathologies ranging from cancer, allergies and autoimmune diseases to cardiovascular and neuropsychiatric disorders. More recently, a major breakthrough has occurred by targeting immunological checkpoints that negative regulate the immune system and play critical roles in self-tolerance, tissue protection and autoimmunity prevention. The antibody-based immune checkpoint inhibitors targeting the cytotoxic T-lymphocyte-associated protein 4 (CTLA4) and the programmed cell death protein 1/programmed death-ligand 1 (PD-1/PD-L1) pathway are in clinical development, thus forming the foundation for a new era of immunotherapy. Despite the exponentially growing entry of mAbs and biosimilars into the clinic, several limitations hamper their wide exploitation in conditions characterized by complex aetiology and multifaceted clinical manifestations. Importantly, mAbs lack oral availability and can engender cellular and humoral immune responses. The resulting production of anti-drug antibodies (ADA) may neutralize the therapeutic effects of the drug *in vivo* and/or alter its pharmacokinetic properties. Alternatively, low molecular weight molecules remain an effective approach for immunomodulatory drug development and repurposing. By controlling specific signalling pathways, small molecules such as protein kinase inhibitors (PKIs) often potentiate or replace mAbs in the therapeutic armamentarium. In the case of PKIs, the choice of therapeutic target is certainly a critical issue. The characterization of the broad spectrum of PKI-target interactions and off-target effects is important to define not only the molecular basis of action and of adverse drug reactions, but also the therapeutic indications.

In conclusion, targeted immunotherapeutics are changing the landscape of Immunopharmacology. Despite the success, the long-term clinical benefit of these agents is still limited to a small subset of patients and indications. Interestingly, the idea of pan-modulators exhibiting efficacy in multiple disorders seems incorrect, whereas the generation of new immune-related toxicity profiles requires specific management. Testing a novel concept in this field is extremely complicated and expensive. Yet, given the growing therapeutic impact of targeted immunotherapeutics, it is important to fully characterize their properties and general management.

IMMUNE-ONCOLOGY: YESTERDAY, TODAY AND TOMORROW

DR. CARLOS SILVA.

Servicio de Oncología Clínica, Hospital Británico, CABA, Argentina

The immune system has the potential of destructing tumors causing no damage to normal tissue and displaying a long-term memory. In the last 30 years, immuno-oncology research has provided solid evidence that this fact is true by a process known as immunosurveillance. Immuno-Oncology studies the interface between oncology and immunology and is a growing research area that led to cancer immunotherapy: treatments that harness and enhance the immune system against cancer. Immunotherapy represents the most promising new cancer treatment approach since the development of the first chemotherapies in the earlies 40s. Immunotherapy has been an effective treatment for different types of cancer but especially those that harbor a high rate of mutations as melanoma and lung cancer. One of the advantages of immunotherapy versus chemotherapy and radiation is that side-effects are more tractable and many types do not require treatment interruption. Side-effects are usually related to stimulation of the immune system and can vary from minor symptoms of inflammation to major disruptions as autoimmune disorders. In addition, due to the “immunological memory” cancer immunotherapy overall response is often durable and some patients have achieved cancer remission that can be maintained even after treatment is completed.

A promising avenue of immunotherapy is the use of immune checkpoint inhibitors. These novel drugs in general are monoclonal blocking antibodies that targets specific molecules that negatively regulates the immune response. Thereof, by blocking inhibitory molecules or, alternatively, activating stimulatory molecules, these treatments are designed to unleash or enhance pre-existing anti-tumor immune responses. Several checkpoint inhibitors, targeting multiple different checkpoints, are already been approved for first line treatment and some others are currently being tested in clinical trials.

For example, a very promising immunotherapy to the treatment of metastatic melanoma and lung cancer is the use of PD-1/PD-L1 checkpoint inhibitors. PD-1 is found on activated lymphocytes and upon PD-L1 binding weakens the immune response. In March 2015, the FDA approved the PD-1 checkpoint inhibitor nivolumab (Opdivo®), made by Bristol-Myers Squibb, for the treatment of advanced squamous NSCLC that has stopped responding to chemotherapy. This approval was based on results of a phase III trial in which patients receiving nivolumab lived, on average, 3.2 months longer than patients receiving standard chemotherapy. This translates into a 40% reduced risk of death compared to standard chemotherapy. In October 2015, the FDA expanded its approval of nivolumab to include non-squamous NSCLC. This approval was based on the results of a phase III trial that showed that patients who received nivolumab lived an average of 12.2 months compared to 9.4 months for those receiving standard chemotherapy. In addition, pembrolizumab (Keytruda®), a PD-1 checkpoint

inhibitor made by Merck, was approved in October 2015 for patients with NSCLC. In a phase I clinical trial, about 22% of NSCLC tumors tested had PD-L1 expression at a level of at least 50%. This subset of NSCLC had a response rate of 41%. However, whereas significant clinical responses have been achieved in several patients, others maintain only short-term and new checkpoint inhibitors are intensely being searched.**SIMPOSIA VIII**

IMMUNOLOGICAL PROCESSES UNDERLYING THE SLOW ACQUISITION OF IMMUNITY TO BLOOD-STAGE MALARIA

DIANA HANSEN
(Infection and Immunity Division, The Walter and Eliza Hall Institute of Medical Research, Victoria, Australia)

Naturally acquired immunity to malaria develops only after many years of repeated exposure to *Plasmodium* parasites. Despite the key role that antibodies play in protection against malaria, the cellular processes underlying the slow acquisition of immunity are unclear. Children in high transmission settings that experience frequent malaria clinical episodes are characterized by a delayed development of parasite-specific memory B cells (MBC), suggesting that the inflammatory factors contributing to disease hinder these responses. We have recently addressed this hypothesis using a pre-clinical model of severe malaria and found that the same inflammatory pathways mediating disease syndromes impair germinal centre (GC) responses and the development of MBC and long-lived plasma cells required for antibody-mediated control of parasitemia. To further define molecular mechanisms by which malaria-driven inflammation impairs the induction of protective immunity, the development of GC responses to *P. berghei* ANKA was examined in mice deficient in the T helper 1-defining transcription factor T-bet. Genetic deletion of T-bet significantly improved T follicular helper (Tfh) cell differentiation rates, which translated in enhanced GC and parasite-specific antibody responses to infection. Interestingly, malaria-driven T-bet expression not only affected the T cell compartment but also directly influenced B cell function, as infection of T-bet$^{fl/fl}$CD23^{Cre} mice revealed that intrinsic expression of T-bet in mature B cells during infection influences the induction of humoral immunity by modulating the cellular dynamics of the GC reaction as well as the quality of the parasite-specific antibody response. Thus, these data suggest that inflammatory pathways mediated by T-bet in response to symptomatic malaria negatively impact the development of long-term humoral immunity by compromising T cell help for antibody formation and by directly influencing B cell activity.

ADAPTIVE IMMUNITY OF BACTERIA

KONSTANTIN SEVERINOV
(Waksman Institute, Rutgers University, New Brunswick, New Jersey, USA)

CRISPR-Cas is a common adaptive RNA-guided prokaryotic immunity mechanism that limits the spread of mobile genetic elements such as phages and plasmids. A CRISPR-Cas system is composed of two seemingly independent modules. Cas proteins from the adaptation module are responsible for recording prior encounters with mobile genetic elements by incorporating fragments of foreign DNA into CRISPR array. Small protective RNAs generated after CRISPR array transcription are used by the interference module Cas proteins to locate complementary nucleic acids and destroy them. I will discuss how the activities and substrate preferences of these two functional modules are tightly coordinated to provide efficient defense against foreign DNA.

FROM SOIL TO CYTOSOL: THE PATHOGENIC TRANSITION OF THE ENVIRONMENTAL BACTERIUM *LISTERIA MONOCYTOGENES*

NANCY FREITAG
(University of Illinois, College of Medicine at Chicago, Chicago, USA)

Listeria monocytogenes is an important agent of foodborne infections and can cause serious invasive disease with a high mortality in susceptible individuals. This bacterium is a ubiquitous environmental organism that can survive in the soil as a saprophyte, but which maintains an ability to invade and replicate within the cells of humans and animals. While environmental microorganisms are numerous, relatively few have the capacity to cause human disease, thus we are interested in how *L. monocytogenes* balances its life as an environmental organism with the lifestyle of a human/animal pathogen. Key to the ability of *L. monocytogenes* to transition to life within mammalian cells is the regulated activity of a transcriptional activator known as PrfA. PrfA is required

for the activation of virulence gene expression within the host and contributes to the physiological adaptation of *L. monocytogenes* to the host cell environment. In addition to regulating bacterial gene products required for host cell invasion, intracellular growth and cell-to-cell spread, PrfA regulates the expression of a bacterial pheromone that enhances bacterial escape from host cell vacuoles by enabling the bacterium to sense the confined space of the vacuole. PrfA also controls the expression of critical secretion chaperones that are required for the folding and stabilization of bacterial virulence factors within the host cell. Overall, our studies highlight the diversity of mechanisms exploited by *L. monocytogenes* to enable bacterial growth within highly diverse habitats ranging from the soil to the cytosol of human cells.

IMPACT OF ANTIMICROBIAL ACTIVITY OF BACTERIAL PEPTIDES ON MULTI-DRUG RESISTANT PATHOGENS: EFFECT IN HUMAN AND VETERINARY MEDICINE

MÓNICA SPARO
(Universidad Nacional de La Plata, La Plata, Argentina)

Resistance to antibiotics has become a threat to global public health and is driving novel research into the development of new antimicrobial drugs. Antimicrobial peptides produced by different gram positive bacterial strains, particularly lactic acid bacteria (lactobacilli, bifidobacteria, lactococci, pediococci, enterococci), has aroused growing interest in the light of the decreasing effectiveness of antimicrobials against severe human and animal infections. Innovation is needed for the development of new drugs and for combination therapies with conventional antibiotics. By targeting different mechanisms of resistance simultaneously, combination therapy might help slow the emergence of resistance. These novel antimicrobial compounds are commonly described as small ribosomally synthesized peptides that are secreted by bacteria and inhibit the growth of closely related species; although some of them exhibit broad-spectrum inhibitory/bactericidal activity (Nisin, AP-CECT7121). Peptides function by inserting themselves into the plasma membrane of target bacteria, forming pores and causing lysis. In addition to their food-safety applications, these peptides can be used effectively in treatment of human and animal bacterial infections. Susceptible pathogens include multi-drug-resistant bacteria as hospital methicillin-resistant *Staphylococcus aureus* (H-MRSA), community methicillin-resistant *Staph. aureus* (Co-MRSA), *Staph. pseudointermedius*, high level vancomycin-resistant *Enterococcus* (VRE) strains and other pathogens resilient to treatment as *Listeria monocytogenes*, *Streptococcus agalactiae* and anaerobic spore-forming bacteria (*Clostridium* spp.). Advantage of these bacterial peptides: diverse repertoire, target specific, food-safe grade substances, synergy with and reduce cytotoxicity of antibiotics. However their main weakness: potential for resistance development and sensitive to proteolysis.

NOW YOU SEE ME, NOW YOU DON'T! SELECTION STRATEGIES EMPLOYED BY THE OOCYTE TO BE CORRECTLY FERTILIZED

HÉCTOR A. GUIDOBALDI
(Instituto de Investigaciones Biológicas y Tecnológicas, CONICET, Facultad de Ciencias Exactas, Físicas y Naturales, Universidad Nacional de Córdoba, Córdoba, Argentina)

Polyspermy is the fusion of two or more spermatozoa with the same oocyte. In some organisms, like birds, it is necessary for a normal fertilization and embryo development, and it is known as physiological polyspermy. However, in many taxa, including mammal's polyspermy results in the death of the embryo, and is called pathological. From an evolutionary point of view, the latter is expensive for females since: i) it reduces the fitness by the loss of viable embryos, ii) the energy investment destined to block the polyspermy could be invested in producing more oocytes, and iii) it can prevent fertilization if the mechanism of blocking is too efficient. Hence females will be under a selection pressure to optimize their response mechanism to reduce the risk of polyspermy. Meanwhile, males compete with others in a race for fertilization. And the selection pressure, promotes the production of many spermatozoa highly efficient to fertilize the oocyte. Being, the pathological polyspermy a collateral damage of that sperm competition. In this context of gender conflicts, communication between gametes, mediated by chemotaxis, arises as a coordinating mechanism that could reconcile the differences of interests between males and females. In the 90's it was discovered that mammalian spermatozoa could be attracted by substances released during ovulation. The characterization of the sperm chemoattraction mechanism showed that only a subpopulation of capacitated spermatozoa (those in optimum physiological conditions for fertilization) could

be chemoattracted by substances released by cumulus cells that surrounds the oocyte (like progesterone or CRISP1). These substances, can diffuse passively along the cumulus and beyond, forming a concentration gradient of attractant that orients the spermatozoa inside the oviduct towards the oocyte. However, once fertilization occurs, this attraction system remains active keeping the oocyte "visible" for those spermatozoa seeking to fertilize. Up to date, the polyspermy blocking mechanisms characterized in mammals (removal of binding proteins or mechanical blockage at the level of the zona pellucida) take several minutes to hours to be effective, and there is no rapid blockage mechanism characterized yet. Recently, we have discovered that capacitated spermatozoa can be chemorepelled, also by a progesterone concentration gradient but in the presence of zinc in the culture medium. This is an interesting discovery, since the oocyte stores zinc in micro-vesicles next to the plasmatic membrane. And, immediately after fertilization, zinc is released outside of the oocyte by exocytosis. Hence, the zinc released could convert the progesterone attraction gradient into a repulsion one to "hide" the oocyte from the sight of the capacitated spermatozoa and reorient them away from the fertilized oocyte. Then, the combination of chemoattraction and chemorepulsion, would allow to regulate the fertilization compensating the interests of both genders. Chemoattraction would allow sperm competition, but once fertilized the oocyte, chemorepulsion could discourage it immediately, preserving the normal development of the embryo. The combination of both mechanisms, optimizes the energy invested by the oocyte to blockade the polyspermy and guarantees the normal fertilization.

SPERMATIC ALTERATIONS AS MARKERS OF HYPERCHOLESTEROLEMIA AND THEIR IMPROVEMENT WITH OLIVE OIL CONSUMPTION

MIGUEL FORNES

(Instituto de Histología y Embriología "Dr. Mario H. Burgos", Universidad Nacional de Cuyo, Mendoza, Argentina)

Grease- enriched food is associated to hypercholesterolemia. But, a slight reduction of fat linked to virgin olive oil (VOO) ingestion is enough to decrease diet-induced hypercholesterolemia. Moreover, the seminal and sperm parameters altered under hypercholesterolemic environment were also recovered by VOO. Cholesterol is a key molecule in sperm life because it is involved in several steps of sperm physiology: sperm capacitation, acrosomal reaction among others less recognized. In this sense, an increment in sperm membrane cholesterol would not be strange to interfere with the process, promoting a decrease in: p-Y protein (capacitation marker) and acrosomal index induced by progesterone. Both parameters are also accompanied by teratozoospermia and a reduced sperm cell number in semen. The last detrimental effects of high cholesterol could be attributable to defects at seminiferous tubules, low efficient of the spermatogenetic epithelium and failed spermiogenesis. In morphological detailed analysis it was observed that manchete/acroplaxoma arrangement was disrupted. The acrosomal and nuclear rings normally are pulled down, toward the implantational site of flagellum, by the manchette, a specific tridimensional microtubule complex. Under grease food intake, these structures were asymmetric generating abnormal sperm head and flagella implantation out of the central sperm axis. Furthermore, microtubules and actin filaments, that normally co localize during sperm conformation, does not match under high serum cholesterol. Interestingly, VOO incorporated to diet promotes a re-colocalization and normal sperm development. It is also observed that apoptotic cells appear in seminiferous tubules, as well as uncorrelated spermatogonial and spermatocyte cells frequency; any of them would contribute to explain the tubular decreased efficiency. Fortunately, VOO added to a grease diet recovers the normal spermatogenetic way in adult rabbits promoting normal sperm parameters.

MORPHOLOGICAL AND FUNCTIONAL STUDY OF *LEPTODACTYLUS CHAQUENSIS* TESTIS

LUCRECIA IRUZUBIETA

(Facultad de Bioquímica, Química y Farmacia, Universidad Nacional de Tucumán, Tucumán, Argentina)

Leptodactylus chaquensis is an anuran amphibian belonging to the family *Leptodactylidae* and in our country it is considered as an autochthonous species of the regions of the NOA and NEA. In recent years a marked decline in *Leptodactylus chaquensis* populations has been observed. For this reason, the need arises to implement conservation techniques that consider as main actions the controlled breeding in captivity of the species at risk, with subsequent reinsertion of specimens to their natural habitat. In order to develop these actions, it is important to know the reproductive biology of these species, which in the case of *Leptodactylus chaquensis* is very limited. Taking into account these antecedents in this presentation some morphological and functional aspects of the testis of this species of regional importance it will be comment.

The analysis by optical and ultrastructural microscopy indicates that the histo-architecture of the gonads of *Leptodactylus chaquensis* shows characteristics similar to that of other anuran amphibians and the observations at

the level of transmission electron microscopy, allowed to postulate a diagrammatic sperm scheme.
In the testes of this species, apoptosis was observed as a physiological process, with a higher percentage of occurrence during the reproductive period. An interesting finding was the presence of this type of programmed death in some Sertoli cells with sperm anchored to their cytoplasm, which led us to suggest that this could be an alternative spermiation mechanism.
For the first time in amphibians the presence of Ca^{2+}, calbindin - 28KD and calmodulin could be determined in Sertoli cells, germ cells and gametes indicating the importance of the cation and its homeostasis, at the cellular level, in different physiological processes of the gonad. Thus, in germline cells the cation would be involved in cell growth and differentiation, whereas in the sperm, Ca^{2+} -ATPase activity localized in the acrosomal membranes, associated with Ca^{2+} deposits in the acrosomal vesicle would represent a cation storage system, thus avoiding a premature acrosomal reaction. To corroborate this finding, the biological tests allowed determining that the sperm treatment with 2mM $CaCl_2$ induces the acrosomal reaction effectively.
When studying endocrine regulation of gonadal function, it was determined that FSH, LH and hCG induce spermiation and secretion of steroid hormones in a dose and time dependent manner. FSH is more effective as inducer of spermiation, whereas LH is more effective in stimulating the secretion of steroid hormones.
Overall, both morphological and functional results obtained under our experimental conditions, allow us to suggest that *Leptodactylus chaquensis* would be considered a species with a potentially continuous reproductive cycle.

ENVIRONMENTAL FACTORS AND THEIR EFFECTS ON MALE REPRODUCTION

CECILIA PAPARELLA
(Facultad de Ciencias Bioquímicas y Farmacéuticas, Universidad Nacional de Rosario, Rosario, Argentina)

A significant deterioration of male reproductive health has been observed in the last decades. Occupational exposure to toxic substances and environmental contaminants (heavy metals, solvents, agrochemicals, and even heat sources) has been identified as one of the possible causes. These chemical compounds, whether natural or synthetic, affect the male hypothalamic-hypophyseal-gonadal axis or spermatogenesis directly, resulting in an alteration of the seminal canal. The main routes of entry of these toxic substances into the body are inhalation and absorption. Occupational exposure affects the reproductive system, and the resulting damage depends on the length of time of exposure, the concentration of the contaminant in the environment, the protection/safety measures in place, and individual susceptibility. Many of these compounds are known endocrine disrupting chemicals (EDC). They mimic natural hormones, and interfere with endocrine homeostasis by altering the estrogen-androgen-thyroid hormone balance during growth and in future generations. Alterations in different reproductive parameters associated with intrauterine exposure to EDC have been observed in both men and women. The mechanism of transgenerational transmission involves non-genomic modifications in germ cells, changes in DNA methylation or changes in histone acetylation. Alterations in spermatic structures involved in sperm viability and fecundity, such as sperm morphology, DNA integrity, chromatin condensation, and sperm membrane functionality, have been observed in men occupationally exposed to solvents. Agrochemicals (pesticides and fertilizers) interfere with the sperm synthesis and maturation processes. Subjects exposed to these toxic substances show a decrease in sperm concentration and in the percentage of progressive motile spermatozoa, and an increase in germ cell concentration and in morphologically abnormal spermatozoa. In addition, occupational exposure to high temperature sources (as occurs with bakers, cooks, welders, and steel workers) or prolonged exposure of the testes to body temperature (as is the case of bus/truck/taxi drivers and cyclists who remain seated for many hours a day) disturb the synchronous development of the spermatogenic cycle. Seminal analysis shows an increase in germ cell concentration and elevated sperm DNA fragmentation, affecting male reproductive function. Workers exposed to the aforementioned environmental factors are at increased risk of male infertility. The effects of exposure to environmental factors must be evaluated when analyzing male fertility in couples with unexplained infertility. The use of many these toxic substances is currently forbidden in some countries. However, it is necessary to implement strict public health policies aiming to control the use and risk of exposure to these chemicals, in order to reduce their deleterious effect on male reproductive function.

EFFECT OF LIPID-PACKING AND MEMBRANE CURVATURE ON PROTEIN MEMBRANE INTERACTIONS

ERNESTO AMBROGGIO
(Centro de Investigaciones en Química Biológica de Córdoba, CONICET; Facultad de Ciencias Químicas, Universidad Nacional de Córdoba, Córdoba, Argentina)

The understanding of how membrane physics control biological processes in cells is a key step to better comprehend biology. One aspect is how lipid packing and membrane curvature dictates the rules for lipid/protein interactions and/or protein sorting. Here, and based on previous, I will introduce two different cases of how this physical principles could modulate the association and trafficking of proteins: 1-how lipid packing and membrane curvature, together with membrane order, may impact on the sorting of transmembrane SNARE proteins that reach the golgi and are further transported to the plasma membraen; 2-how in-situ phospholipase activity induces lipid-packing defects that are “sensed” by ALPS, the amphipatic lipid packing sensor motif of ArfGAP1.

HAMPERING THE INACTIVATION OF THE IMMUNOMODULATORY PROTEIN GALECTIN-1 IN INFLAMMATORY MICROENVIRONMENTS

SANTIAGO DI LELLA

(Instituto de Química Biológica-Ciencias Exactas y Naturales, CONICET; Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Buenos Aires, Argentina)

In the past decade, significant efforts have been made to delineate the intracellular and extracellular functions of galectins, multifunctional proteins capable of monitoring glycan changes during fundamental biological processes. Their widely conserved structures, exquisite, although in some cases promiscuous, carbohydrate specificity, and their ability to modulate a variety of biological processes have captivated a broad range of scientists from different disciplines. However, despite considerable efforts in dissecting the functions of these glycan-binding proteins, it is still not clear how structural and biochemical aspects of these proteins can influence their biological activities.

Galectin-1, a proto-type member of the galectin family displays at a glance a structure that appears to be quite simple, although a few peculiarities make it highly versatile. Firstly, even thought its binding domain is a monomer, a subtle homodimerization equilibrium at physiologic concentrations is critical to modulate its biological activity. Moreover, the complex kinetics and thermodynamic equilibria critically govern the function and signaling of this lectin by allowing interactions with a preferential set of glycosylated receptors. Furthermore, the presence of some key amino acid residues, such as an unusual number of cysteine residues or a few environmental sensor residues, appears to govern key properties of galectin-1 functional activity.

We have studied structural and chemical determinants of the galectin-1 protein that in a precise and subtle manner modulate its biological function, by combining experimental and computational approaches. Particularly, inactivation of the protein due to specific physico-chemical conditions present in inflammatory microenvironments will be discussed. We aim to integrate structural, biochemical, and functional aspects of this critical carbohydrate-binding protein and will discuss their implications in physiologic and pathologic settings with the ultimate goal of designing potential galectin-based therapeutic agents.

X-RAY PROTEIN CRYSTALLOGRAPHY AS A TOOL FOR THE STUDY OF BACTERIAL VIRULENCE FACTORS

MARÍA NATALIA LISA

(Laboratorio de Microbiología Molecular y Estructural, Instituto Pasteur de Montevideo, Montevideo, Uruguay)

Cells use signal transduction to sense the environment and regulate central processes in response to environmental stimuli. Reversible protein phosphorylation has evolved as a ubiquitous molecular mechanism of protein regulation. Indeed, the flow of information from the outside to the inside of bacterial cells is largely directed by histidine (His) kinases in two component systems and by eukaryotic-like protein kinases. Work in *Mycobacterium tuberculosis* (*Mtb*) reinforces the idea that phosphorylation on serine (Ser), threonine (Thr) and tyrosine (Tyr) is central to bacterial physiology and pathogenesis, and that the corresponding phospho-systems share similarities to those in eukaryotes (Sherman and Grundner, 2014, *Mol Microbiol*). However, as novel functions and components of bacterial O-phosphorylation are identified, distinct differences between pro- and eukaryotic phospho-signaling systems become apparent, revealing specific protein:protein interfaces that could be exploited for the development of selective drugs with unconventional modes of action. In this talk I am going to present recent advances in the understanding of the signal transduction pathway involving PknG (O’Hare *et al*, 2008, *Mol Microbiol*), a unique multi-domain Ser/Thr protein kinase (Scherr *et al*, 2007, *PNAS*; Lisa *et al*, 2015, *Structure*) that senses amino acid availability to control metabolism and virulence of *Mtb* (Rieck *et al*, 2017, *Plos Pathogens*), and which has a conserved function in amino acid homeostasis amongst the Actinobacteria (Cowley *et al*, 2004 *Mol Microbiol*; Niebisch *et al*, 2006, *J Biol Chem*).

SUSTAINED MECHANICAL STRESS ALTERS THE DYNAMICS AND MOLECULAR RESPONSE OF FOCAL

ADHESIONS IN MAMMARY EPITHELIAL CELLS

LORENA SIGAUT
(Instituto de Física de Buenos Aires, CONICET, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Buenos Aires, Argentina)

Cells are constantly subject to different external mechanical stimuli under normal physiological conditions. Cellular response and adaptation to these mechanical stimuli are crucial in cellular functions and processes[1]. Many of the biological responses to external forces are originated in specialized structures, focal adhesions, which mechanically connect cells with the extracellular matrix via integrin membrane receptors. Focal adhesions are large, transient multiprotein complexes, their formation, development and disassembly are force-dependent[2]. Characterizing how these structures dynamically respond in the presence of a mechanical stimulus is essential for understanding different processes, such as cell adhesion, migration, motility and proliferation.

In this work, we explored the changes generated in the dynamics of focal adhesions, in HC11 non-tumorigenic mouse mammary epithelial cells, in response to a global external mechanical stimulation that resembles the physiological stimuli to which these cells are subjected. To perform controlled and reproducible mechanical stimulus we use a mechanical stretching device[3] that allows sustained equibiaxial stretching of an elastic silicon membrane in which cells are grown, while evaluating the cell-responses by different fluorescence microscopy techniques. We were able to follow focal adhesion dynamics during stretching experiments, by imaging living cells expressing fluorescently tagged proteins, observing an enhanced persistency of focal adhesions as well as an increase in their size. At a molecular level, we explored the effect of external equibiaxial strain on two adhesion proteins postulated as mechanosensors: zyxin and vinculin. We found that increasing normal strain in HC11 living cells, not only induce focal adhesions persistency together with an increase in their size, but also raises molecular tension across the protein vinculin within focal adhesions and significantly decreases dissociation rates of zyxin from the focal adhesion complexes. Although mechanoresponses of zyxin and vinculin have been widely studied, the influence of a direct mechanical change of the substrate on these proteins at a molecular level has not been established before.

THE GENETIC BASIS OF DIFFUSE LARGE B CELL LYMPHOMA

LAURA PASQUALUCCI
(Pathology and Cell Biology, Columbia University, New York, USA)

Diffuse large B cell lymphoma (DLBCL), the most common subtype of B cell lymphoma in adults, is a molecularly and phenotypically heterogeneous disease that arises from the malignant transformation of B cells arrested at different stages within the germinal center (GC). Over the past decade, considerable progress has been made in our understanding of the molecular pathogenesis of these tumors, owing to the rapid expansion of genomic technologies that allowed us to interrogate the genome/transcriptome of the cancer cell in a comprehensive and unbiased fashion. These studies revealed that DLBCL is characterized by significant genomic complexity, harboring on average 50-100 somatic point mutations and copy number aberrations per case; they also uncovered multiple previously unappreciated genes/pathways that are disrupted by genetic alterations in this disease and may contribute to tumor initiation and expansion. Interestingly, many such lesions hijack transcriptional networks and biological programs that play key roles during the normal GC reaction, where they need to be dynamically and tightly controlled. This wealth of new information led to our current view of the DLBCL genomic landscape, which includes i) alterations that are shared across the two main “cell-of-origin” subtypes of the disease [i.e. the germinal center-like (GCB) DLBCL and the activated B cell-like (ABC) DLBCL]; these involve perturbation of histone/chromatin modifying genes, deregulation of BCL6 activity through multiple mechanisms, and evasion from immune surveillance mechanisms (by loss of B2M/HLA-I and CD58); and ii) lesions that are preferentially or specifically associated with GCB-DLBCL and ABC-DLBCL, indicating that these two subtypes utilize distinct oncogenic pathways.

Among the newly identified “shared” lesions, inactivating mutations in epigenetic modifier genes, including the methyltransferase CREBBP and the acetyltransferase KMT2D, emerged as the most common events in DLBCL, suggesting a central role for epigenetic dysreg-

ulation in the malignant transformation process. Interestingly, mutations of these two genes represent early events during the history of tumor clonal evolution, suggesting an early role in lymphomagenesis. *In vivo*, loss of KMT2D or CREBBP synergizes with BCL2 deregulation to promote tumor development, documenting their role as tumor suppressor genes. Collectively, these findings have provided a molecular framework for the development of therapeutic regimens that may target specific oncogenic addictions in a precision medicine approach.

TARGETING NUCLEAR TRAFFICKING: THE WAY OUT

LEANDRO CERCHIETTI
(Weill Cornell Medicine, Cornell University, New York, USA)

The nuclear pore complex is best known for its primary function as the key regulator of molecular traffic between the cytoplasm and the nucleus, however this structure is also an important regulator of gene expression by coordinating the delivery of genetic material to the cytoplasmic protein synthesis machinery. Transport of almost all macromolecules into and out of the nucleus is achieved through a common active mechanism that requires the assistance of soluble nuclear transport factors (NTFs) and transport signals, which together form the "soluble phase" of nuclear transport. Most NTFs belong to the karyopherin family of proteins. Exportin 1 (XPO1) is a conserved and well-characterized karyopherin exporting protein that binds and exports more than 200 proteins from the nucleus to the cytoplasm. XPO1 binds its cargo in the nucleus via the canonical leucine-rich nuclear export signal domain. The complex is then translocated through the nuclear pore complex in the cytoplasm where the cargo is released from XPO1. Since the function of several classes of proteins is highly affected by their intracellular localization, XPO1 is often considered a housekeeping gene whose exporting activity regulates multiple functions in normal cells. However, our group found that XPO1 is frequently amplified and overexpressed in aggressive B-cell lymphomas that are refractory to treatment. Solid tumors and leukemia cells also overexpress XPO1, prompting the development of XPO1 inhibitors as anti-neoplastic agents. The observation that XPO1 inhibitors can be safely used in the clinical setting indicates that cancer cells are more dependent on XPO1 exporting activity for proliferation and survival than normal cells. Although the general consensus is that XPO1 inhibitors exerts its anti-neoplastic function by affecting the nuclear localization of key oncosuppressors proteins, we have reported that a key mechanism by which XPO1 inhibitors kill cancer cells is related to the nuclear entrapment of a sub-set of proteins that binds mRNA, among which eIF4E. As a consequence, XPO1 inhibition reduces the delivery of a sub-group of mRNAs to the cytoplasmic protein synthesis machinery decreasing the expression of a sub-group of oncoproteins that are essential for cancer cell survival. In this presentation, I will discuss the mechanisms employed by XPO1 to selectively regulate the expression of oncogenes and how this has been therapeutically capitalized towards precision oncohematology goals.

DECOUPLING THE PROTEOME FROM THE TRANSCRIPTOME: THE STORY OF THE EUKARYOTIC TRANSLATION INITIATION FACTOR EIF4E

KATHERINE BORDEN
(Department of Pathology and Cell Biology, Faculty of Medicine, Université de Montréal, Montréal, Canada)

Recent advances in cancer research have focussed on genome and transcriptomic understanding of cancer. However. global proteomics studies reveal that the transcriptome does not always reflect the proteome. A major question arises: how is the proteome decoupled from the transcriptome? Indeed, alterations in mRNA metabolism at the mRNA export, mRNA processing or translation levels can all contribute to increased protein expression in the absence of increased transcription. The eukaryotic translation initiation factor eIF4E is a prime example of such regulation. eIF4E is an oncoprotein that plays multiple roles in RNA processing driving the conversion of transcripts to protein without altering transcript levels. eIF4E drives the mRNA export and translation of established oncogenic drivers including c-Myc, MCl1, BCL6, hDM2 etc. Indeed, eIF4E regulates about 3500 transcripts at the mRNA export level many of them involved in functionally related roles. In this way, eIF4E can coordinately drive oncogenic networks. eIF4E is elevated in many human cancers including Acute Myeloid Leukemia (AML). Our studies provide mechanistic insights into eIF4E's biochemical activities and our clinical studies demonstrate that targeting eIF4E in AML patients leads to responses.

THERAPEUTIC TARGETING OF LEUKEMIA STEM CELLS

MONICA GUZMAN
(Weill Cornell Medicine, Cornell University, New York, USA)

The majority of patients with acute myelogenous leukemia (AML) die from their disease. Despite that most patients can achieve remission after initial induction therapy, most of them will relapse. Relapse is thought to be the result of ineffective ablation of a population of leukemia cells that are known as leukemia stem cells (LSCs). Elevated levels of LSCs (defined by immunophenotype) at diagnosis are predictive of minimal residual disease (MRD) which, in turn, predicts leukemic relapse, even after myeloablative stem cell transplantation. Thus, in order to improve AML therapy, it is critical to identify therapeutic strategies that effectively eliminate LSCs. We have demonstrated that LSCs possess unique molecular features that distinguish them from their normal hematopoietic stem cells (HSCs) and that such can be exploited to selectively eliminate LSCs without harming HSCs. We have identified novel therapeutic strategies to selectively target LSCs without harming HSCs. Such strategies include compounds derived from natural products, nanoparticles and chimeric antigen receptor T cells.

STRUCTURAL AND FUNCTIONAL PLASTICITY OF MYOSIN V

SIMONA POLO
(Fondazione Istituto di Oncologia Molecolare, Milano, Italy)

In the last few years, the contribution of alternative splicing in human disease has been widely recognised. Unbalanced expression of splicing variants or failure to properly express the correct isoform is undoubtedly part of cancer cell biology. We recently studied alternative splicing of myosin VI, a motor protein with unique functional properties, to find that myosin VI isoforms have mutually exclusive interactors and adopt different conformations (Wollscheid et al. NSMB 2016). Our structural and functional data pointed to an isoform-specific regulatory helix, named α2-linker that acts like a molecular switch, assigning myosin VI to distinct endocytic (myosin VI_{long}) or migratory (myosin VI_{short}) functional roles. This finding is relevant to ovarian cancer, where alternative myosin VI splicing is aberrantly regulated, and exon skipping dictates cell addiction to myosin VI_{short} for tumour cell migration (Wollscheid et al. NSMB 2016).

Interestingly, an isoform switch occurs during epithelial polarization and determines the selective expression of myosin $VI_{long.}$ Indeed, we observed that epithelial cells expressing both isoforms switch on/off their expression according to the culture conditions. In sparse conditions, lung adenocarcinoma cells (A549) and colorectal adenocarcinoma cells (Caco2) express predominantly myosin VI_{short} (that functions in cell migration) but they switch to an almost exclusive expression of myosin $VI_{long.}$ (with endocytic functions) upon reaching confluency and a fully polarized epithelial architecture. This process is reversible as both cell lines switch back to myosin VI_{short} once disaggregated and grown in sparse conditions. This isoform switch mimics the epithelial to mesenchymal transition (EMT) process that leads to the positive selection of myosin VI I_{short} observed in primary ovarian cancer cells and it represents an informative and simple cellular model to study AS regulation at the endogenous level. We are currently identifying and characterizing common splicing-regulated events that occur during the establishment of a fully polarized epithelial architecture and the responsible alternative spicing regulators, which are possibly deregulated during cancer alternative splicing reprogramming.

We also found that myosin VI depletion in non-tumoral cells (hTERT-RPE1 and BJ-5ta) leads to impairment in cell proliferation, caused by a cell-cycle arrest in G0/G1, followed by senescence. This block in cell cycle progression is due to the activation of the p53-p21 axis which occurs independently from DNA damage and might be triggered by the centrosome surveillance pathway. Indeed, myosin VI depletion leads to several centrosomal defects, namely centriole amplification, separation and random orientation. Recent results will be presented.

CULLIN-RING UBIQUITIN LIGASES: FROM SIGNALING TO DISEASE

DANIELE GUARDAVACCARO
(Utrecht University, Utrecht, The Netherlands)

Research in our laboratory focuses on studying the molecular mechanisms through which the ubiquitin system controls fundamental cellular processes and understanding how deregulation of this network leads to human disease. We are especially interested in the role of Cullin-RING complexes, the largest class of E3 ubiquitin ligases in eukaryotes. Cullin-RING ubiquitin ligases (CRLs) share a common catalytic core consisting of a Cullin scaffold and a RING protein which functions as the docking site for ubiquitin conjugating enzymes. The catalytic core of CRL assembles with numerous substrate receptors, which target specific substrates for ubiquityla-

tion. Due to the great diversity of their substrate receptor subunits, over 350 distinct CRLs are present in eukaryotic cells, establishing these enzymes as major mediators of ubiquitin conjugation and key regulators of a wide array of biological processes. Despite their importance, our knowledge of the biological functions, mechanism of action, regulation and physiological partners for most CRLs remains poor. Moreover, the majority of CRLs remains with no established substrates. Therefore, the major goal of our research program is to study the functions of orphan CRLs and systematically identify their biologically significant substrates as well as investigate how deregulation of CRL-mediated ubiquitylation contributes to pathogenesis.

AUTOPHAGY AND PATHOGEN-CONTAINING COMPARTMENTS: SIGNALING TO CONTROL LIFE AND DEATH

MARÍA ISABEL COLOMBO

(Instituto de Histología y Embriología "Dr. Mario Burgos", CONICET, Universidad Nacional de Cuyo, Mendoza, Argentina)

Intracellular pathogens use sophisticated mechanisms to overcome host cell defenses and replicate successfully. Autophagy, a self-degradative process, is a critical cell defense mechanism against invading microorganisms, but certain bacteria avoid or actively subvert autophagy to promote their own replication. We have previously demonstrated that autophagy plays a very important role against *Mycobacterium tuberculosis.* During infection *M. tuberculosis* secrets proteins to evade host cell defense mechanisms. Two of these proteins CFP-10 and the hemolysin ESAT-6, encoded by the region of differentiation 1(RD1), are key in mycobacteria pathogenesis. We have previously shown that *M. marinum*-containing phagosomes are decorated with the autophagic protein LC3. However, this recruitment was not observed in cells infected with *M. marinum* deleted for RD1, indicating that this region is critical for autophagy targeting. Likewise our studies indicate that ESAT-6 is critical for autophagy recognition of *M. tuberculosis.* As expected, GFP-LC3 was recruited to phagosomes containing *M. tuberculosis* wt but not the ΔESAT-6 deletion mutant. These and other evidences indicate that *M. tuberculosis* damages the membrane of the mycobacterium-containing phagosome.

Coxiella burnetii, the etiologic agent of Q fever, is a Gram-negative obligate intracellular bacterium that develops a large *Coxiella* replicative vacuole (CRV) that has late endosome-lysosome characteristics with autophagic features (i.e. LC3 recruitment). Indeed, autophagy activation favors bacteria replication. Our present results demonstrate for the first time, that in a population of *Coxiella*-containing vacuoles the CRV membrane is damaged and, as a consequence, the CRV loses transiently its acidic pH. We propose that the autophagic pathway favors *Coxiella* infection by contributing to the repair of the damaged replicative compartment.

Staphylococcus aureus is a microorganism that causes serious infectious processes in humans. After internalization, this pathogen escapes from the phagosome to the cytoplasm. We have shown that before escaping *S. aureus* resides in a phagosome that recruits LC3. This recruitment depends on the toxin a-hemolysin (Hla), secreted by the bacteria. Very recent results from our laboratory indicate that *S. aureus* at early times after infection generates dynamic tubular structures that are labeled by LC3. By using specific markers we have determined that those tubular structures correspond to novel membranous compartments. Interestingly, a *S. aureus* strain deficient in Hla was unable to generate the LC3-labeled tubules.

Taken together our results contribute to understand the behavior of pathogens with different intracellular life styles that share some common features on the targeting by the autophagy machinery that somehow allows pathogen survival.

AUTOPHAGY IN PANCREATIC DISEASES

MARÍA INÉS VACCARO

(Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, Buenos Aires, Argentina)

The study of the molecular mechanisms that human cells put in place in response to the disease is a very active area in scientific research in medicine. Our work is focused on the molecular mechanisms involved in the early events that occur in pancreatic cells during non communicable diseases. In the search for new molecules that are differentially expressed during acute pancreatitis we clone a new transmembrane protein that we call Vacuole Membrane Protein 1 (VMP1). We found that VMP1 triggered autophagy in mammalian cells. Autophagy is a highly conserved process in evolution by which the cell degrades cytoplasmic components including organelles. Autophagy has been linked to a variety of pathological processes such as neurodegenerative diseases and tumorigenesis, which highlights its medical importance. We demonstrate that VMP1 mediates a new type of selective autophagy that acts as a defense mechanism in cells producing export proteins. Also, VMP1 participates in the mechanisms of resistance to death of pancreatic tumor cells and is induced by cancer microenvironment and its interaction with specific plasma membrane proteins marks a new initiation site for autophagy in mam-

malian cells. In this lecture, we will discuss the role of autophagy and its molecular steps as a cell response to complex pathologies such as cancer, inflammatory bowel diseases, pancreatitis and diabetes. We think that the study of the molecular mechanisms that the cells activate in response to human disease will allow to develop new and more rational therapeutic strategies.

IN-CELL NMR AS A TOOL FOR IN SITU STRUCTURAL BIOLOGY

ANDRÉS BINOLFI
(Laboratorio Max-Planck de Biología Estructural, Universidad Nacional de Rosario, Rosario, Argentina)

The structure and function of proteins depend on multiple cellular factors such as localization, post-translational modifications and interactions with biological partners. However, most protein structural studies are typically performed on isolated samples, under conditions that differ substantially from *in vivo* environments of live cells. The question arises whether protein features observed *in vitro* correlate with their intracellular behaviors? In this regard, in-cell NMR spectroscopy represents a powerful method to directly study protein structures in intact cells. Here, we present high-resolution in-cell NMR results on the structural and dynamic properties of the human amyloid protein alpha-synuclein (aSyn) in different mammalian cell types, the aggregation of which correlates with the onset of Parkinson´s disease (PD). Using electroporation to efficiently deliver isotopically enriched aSyn into neuronal and non-neuronal cells, we delineate its intracellular behavior by in-cell NMR spectroscopy.[1] Additionally, we study the cellular repair of oxidation-damaged aSyn by endogenous enzymes and identify C-terminal modifications sites as remaining permanently damaged, which may lead to neuronal toxicity under oxidative stress conditions.[2] These results allow us to better understand the native conformations of aSyn under physiological cell conditions, further enabling future *in situ* investigations of intracellular aSyn aggregation in PD and other related neurodegenerative disease processes.

DENGUE VIRUS CAPSID DYNAMICS: BRIDGING BIOPHYSICS AND MOLECULAR VIROLOGY BY ADVANCED FLUORESCENCE TECHNIQUES

LAURA ESTRADA
(Instituto de Física de Buenos Aires, CONICET; Universidad de Buenos Aires, Buenos Aires, Argentina)

Intracellular dynamics plays a key role in most molecular processes of biological relevance. Many of the studies in this field have been successfully carried out by methods based on the correlation of the intensity fluctuations. Fluorescence Correlation Spectroscopy (FCS), Scanning FCS, Raster Image Correlation Spectroscopy (RICS) and, more recently, spatial pair Correlation Functions (pCF), are powerful techniques that allow studying the motion of particles inside a cell. The pCF measures the time a particle takes to go from one location to another by cross-correlating the intensity fluctuations at specific distances along a line-scan within the cell. The line-scan acquisition implies, however, that the direction along which motion can be studied is predetermined by the chosen scanning pattern. To overcome this limitation we performed a pCF analysis at every pixel along the entire image creating a visual map of the average path followed by the molecules. In this work, we applied a combination of single particle tracking and correlation-based techniques to monitor the subcellular localization of the dengue virus capsid protein undergoing free diffusion into living BHK cells. To this end, we generated a replicating viral RNA with the coding sequence of mCherry fused to capsid. During dengue virus infection, the capsid protein accumulates in nucleolus. However, because viral morphogenesis takes place in the cytoplasm, it is still unknown why and how capsid associates to nucleolus. We used a time course to follow newly synthesized capsid during initial viral RNA translation and replication. Our results show that the directionality of the motion become greater around the nucleolus and it increases with the time passed after transfection.

WHAT CAN WE LEARN ABOUT DRUG MEMBRANE INTERACTION FROM MODEL LIPID MEMBRANES

LAURA FANANI
(Centro de Investigaciones en Química Biológica de Córdoba, CONICET;
Facultad de Ciencias Químicas, Universidad Nacional de Córdoba, Córdoba, Argentina)

Unlike drug selection to achieve specific interaction with protein receptors, compounds that interact with biological membranes seldom do so through specific interactions, but as a sum of weak interactions and entropic factors. The physicochemical bases that govern this phenomenon are not clearly elucidated today. In this talk, I will expose the advances that our laboratory has had in this subject through the study of the interaction of the alkyl esters of L-ascorbic acid (ASCn) to model lipid membranes. These amphiphilic drugs are potent antioxidants that are self-organized in nanostructures called coageles, which have been proposed as ocular and skin permeation enhancers, among other pharmacological uses. On the other hand, we have also studied the interaction with model lipid membranes of the amphiphilic drug hexadecylphosphocholine (HePC) or miltefosine, currently used clinically for the treatment of cutaneous lymphoma and leishmaniasis.

Our studies have highlighted the importance of the structural and rheological properties of the different model lipid membranes used in the interaction of these drugs with these membranes. When an amphiphilic drug is inserted into a biomembrane it must exert a compression on the rest of the membrane components, in such a way that it opposes the lateral pressure. There, the ability of the lipid film to respond to isometric compression and lateral displacement of the components, as well as electrostatic factors (lateral repulsion or between membrane and charged amphiphilic monomers) would condition the insertion of a new molecule into the membrane. From these studies, the compressibility of the membrane is the main physical parameter that governs the incorporation of these drugs.

ASCs are avidly incorporated into lipid membranes in both monolayer and bilayer systems and such incorporation affects the properties of the acceptor membranes differentially according to the length of the hydrocarbon chain of the compounds. These differences were correlated with different pharmacological uses of this family. On the other hand, we address two main issues with regard to the action of HePC: the bases for membrane selectivity and its mechanism as a perturbator agent, which is related to its pharmacological function of cellular lipid homeostasis modulator. HePC is also sensitive to the compressibility of the host membrane by penetrating more favorably into the more easily compressible membranes and less in the membranes rich in cholesterol or that mimic the stratum corneum of skin. This, in turn, alters the phase equilibrium of lipid membranes, which has the potential to modulate the activity of lipolytic enzymes acting on these membranes.

In conclusion, amphiphilic drugs follow a common mechanism of insertion into lipid membranes but with subtle differences according to their chemical structure and amphipathicity, which results in properties that can be exploited in different aspects of their pharmacological use. From what has been learned from these studies we intend to advance in rationally designed, combined therapeutic strategies based on their effect on biomembranes.

A diferencia de la selección de fármacos para lograr interacción específica con receptores proteicos, los compuestos que interaccionan con membranas biológicas pocas veces lo hacen a través de interacciones específicas, sino como una sumatoria de interacciones débiles y factores entrópicos. Las bases fisicoquímica que rigen este fenómeno no están claramente dilucidado en la actualidad. En esta charla, contaré los avances que nuestro laboratorio ha tenido en este tema a través del estudio de la interacción de los esteres alquílicos del ácido L-ascórbico (ASCn) a membranas lipídicas modelo. Éstos fármacos anfifílicos son potentes antioxidantes que se autorganizan en nanoestructuras llamadas coageles, los cuales han sido propuestos como como promotores de la permeación ocular y de piel, entre otras utilizaciones farmacológicas. Por otro lado también hemos estudiado la interacción con membranas lipídicas modelo del fármaco anfifílico hexadecilfosfocolina (HePC) o miltefosina, actualmente utilizado clínicamente para el tratamiento linfoma cutáneo y leishmaniasis.

Nuestros estudios han resaltado la importancia de las propiedades estructurales y reológicas de las distintas membranas lipídicas utilizadas en la interacción de estos fármacos con dichas membranas. Cuando un fármaco anfifílico se inserta en una biomembrana debe ejercer una compresión sobre el resto de los componentes de la membrana, de forma tal que se oponga a la presión lateral. Allí, la capacidad de la película lipídica de responder ante la compresión isométrica y del desplazamiento lateral de los componentes, además de factores electrostáticas (repulsión lateral o entre la membrana y los monómeros solubles de anfifilos cargados) condicionarían la inserción de una nueva molécula a la membrana. De estos estudios surge que la compresibilidad de la membrana constituye el principal parámetro físico que rige la incorporación de estas drogas.

Los ASCn se incorporan ávidamente a membranas lipídicas tanto en sistemas de monocapas como en bicapas y dicha incorporación afecta las propiedades de la membrana aceptora diferencialmente según el largo de la cadena hidrocarbonada de los compuestos. Estas diferencias se correlacionaron con diferentes usos farmacológicos de dicha familia. Por otro lado, abordamos dos cuestiones principales con respecto a la acción de HePC: las bases para la selectividad de la membrana y su mecanismo como un agente perturbador de misma, lo cual está relacionado a su función farmacológica de modulador de la homeostasis lipídica celular. HePC también es sensible a la compresibilidad de la membrana huésped penetrando más favorablemente en las membranas más fácilmente compresibles y menos en las membranas ricas en colesterol o que simulan el estrato corneo de piel. Esto, a su vez altera los equilibrios de fases de las membranas lipídicas, lo que tiene la potencialidad de modular la actividad de enzimas lipolíticas que actúan sobre estas membranas.

En conclusión, los fármacos anfifílicos siguen un mecanismo común de inserción a membranas lipídicas pero con sutiles diferencias según su estructura química y an-

fipaticidad, lo que resulta en propiedades aprovechables en los distintos aspectos de su uso farmacológico. De lo aprendido a partir de estos estudios se pretende avanzar en estrategias terapéuticas combinadas diseñadas racionalmente con base en su efecto sobre biomembranas.

MAPPING THE DYNAMICS OF TRANSCRIPTION FACTORS IN LIVING CELLS AND WHOLE ORGANISMS

VALERIA LEVI

(Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Buenos Aires, Argentina)

Gene expression results from the dynamical recruitment of the transcription machinery and regulatory proteins to specific target genes. Many components of this machinery including transcription factors (TFs), coregulators, chromatin remodelers and RNA polymerases do not distribute homogeneously in the cell nucleus. Determining how the highly dynamical and heterogeneous distribution of transcription-related proteins within the nucleus modulates the expression profile remains as a central challenge in the cell biology field.

Here, we show how the combination of fluorescence fluctuations based techniques and numerical simulations can help us to reveal important aspects of this complex process in living cells. Fluorescence correlation spectroscopy (FCS) methods are based on analyzing the intensity fluctuations caused by molecules moving through the observation volume of confocal or two-photon excitation microscopes. The quantitative analysis of these fluctuations provides important clues regarding the mobility of the molecules and their interactions with other species First, we use FCS to quantify the dynamics of TFs that controls pluripotency in single cells of mouse early embryos. Our study demonstrates that TFs undergo temporally distinct binding events with DNA in the living embryo. Furthermore, we observed that developmentally regulated epigenetic changes create differences in the fraction of the TF Sox2 engaged in long-lived DNA–binding between 4-cell blastomeres. Finally, we demonstrate that these differences in Sox2–DNA binding predict the allocation of the first cells to the inner mass of the embryo, which subsequently contributes most cells of the body.

In addition, we investigated the dynamical organization of TFs in living cells focusing on the glucocorticoid receptor (GR), a ligand-activated transcription factor. This transcription factor is involved in the control of gene expression linked to several processes like inflammation, stress responses, glucose homeostasis, lipid metabolism, proliferation and apoptosis development. We present evidences showing that GR and its coregulator NCoA-2 diffuse within the nucleus and interact with PML bodies, DNA-dependent foci or engage in interactions with chromatin targets. Cross-correlation analyses show that GR and NCoA-2 sequentially interact with foci and glucocorticoid response elements. Moreover, we show that the coregulator and the conformation of the receptor tune the distribution of the receptor among the nuclear compartment. Our results suggest that GR partition in different nuclear reservoirs ultimately regulates the concentration of receptor available for the interaction with specific targets.

SEXUAL EVOLUTION IN THE HUMAN SPECIES

OSVALDO MAZZA

(Servicio de Urología, Hospital de Clínicas "José de San Martín", Buenos Aires, Argentina)

The human species is the result of an evolutionary process that began more than six million years ago and its final product – *Homo sapiens* – reached its developmental peak more than twenty thousand years ago, spreading over the planet from its starting point in Africa and giving rise to a diversity of ethnicities.

All living creatures, including man, sustain life through numerous processes, the most remarkable of which is the ability to reproduce. Reproduction is life's central dogma, allowing its existence and perpetuation. This attribute is known as sexual function. Modern man's sexual function is the result of biological development and cultural influences.

Sexual development in man is rooted in the origins of the species and has changed according to human development. The transformation of animal mating conducts into the diverse and sophisticated ways of man's sexual relations is a consequence of evolution from our primate ancestors, somatic characteristics responsible of our anthropomorphism and sexual characters derived from evolution.

Preservation of the species is a fundamental law of Biology, relying on successful reproductive strategies incorporated along evolution. This biological dogma is so important, that in many species, male, female or both, die after mating or egg release (salmon, squid, bee, mantis). In mammals, mating renders the couple defenseless before predators due to brief loss of control of surroundings and

diminished chances of flight if faced with danger during mating. Thus, mating is remarkably brief. Even in those species closest to man, such as the common chimpanzee *Pan troglodytes*, mating is less than twenty seconds. Man has evolved morphologically and culturally and has transformed his sexuality into an act of pleasure, dissociated from reproductive success, by using techniques already effective in primitive cultures or scientifically controlled in the western world. The search for sexual pleasure has become a conscious and primary aim, above social or moral restraints, leading on occasion to homicide for satisfaction.

Man tries to satisfy his sexuality safely (cave, home, town protect him from external dangers) and his sexual encounters have become longer to increase his pleasure, provided that safety and intimacy conditions are adequate and controllable. Man has experimented extension of pleasure during coitus when compared to simians, an evolutionary trait and unconscious product of what Darwin described as sexual selection.

According to Waldinger, control of preejaculatory vaginal latency (time erect penis remains in the vagina until ejaculation) in the modern human, is an evolutionary trait that betters reproductive strategies. Those who perform adequately, achieve a competitive advantage that makes them desirable in the mechanism of sexual selection. In adverse conditions, sexual performance is shorter, primitive and reflex, lacking cultural contribution. This raises two questions: from which starting point and how has human sexuality developed.

In most simians, except the bonobo chimpanzee, sexual posture involves the male engaging the female from behind. Missionary or face to face position has been probably used since *Australopithecus afarensis*, such as Lucy, 4 million years ago. Lucy's erect posture resulted in a vertical vagina, resembling that of modern woman. A simian's horizontal vagina favors rear copulation with immediate retention of semen, even though the female rapidly becomes active following coitus, even beginning search for another male. If Lucy and her descendants, endowed with a vertical vagina favoring face to face coitus, became active immediately following copulation, loss of semen would probably occur. It was thus biologically necessary for Lucy and the rest of the hominids that followed her up to modern woman, to maintain a resting horizontal position post coitum; an ecstatic period that drove her away from all desire of physical or sexual activity, to allow for semen to coagulate; a period extending pleasure and favoring visual contact with her sexual partner; a post orgasmic period.

This incorporates the idea of generating an identifiable bond with another being to turn to regularly for sexual activity. In contrast to express and uninvolved sex of our ancestors, the great apes, sexual partners will be identified and searched to relive that post orgasmic atmosphere. These bonds gave rise to prolonged and safer infancies, with paternal involvement in the care of the young which, in turn, allowed an evolutionary leap that led to the cerebral and sexual development of *Homo sapiens*.

Which aspects of human nature and sexuality are inscribed in our genes? Which is the contribution of cultural heritage? Which are the biological processes that condition our sex life? Research on the human genome has provided glimpses of the answers to some of these questions, but others remain scientific speculation. Sex, like hunger, is among the main driving forces of human actions and selective drive of cultural evolution.

Like hunger, sex is at the same time, compulsion and appetite. We have dissociated sexual intercourse from its reproductive aim. We exercise our sexuality to satiate a primitive appetite and simultaneously satisfy a social need. We have evolved from communal and carefree sex (chimpanzee?) to possessive sex (gorilla?) to such an extent, that some people are capable of fighting, killing, raping, losing their fortune, their health or even their own life.

Ways and habits in developed societies, intensified in this millennium, allow us to witness the breakup of the human couple. Women practice uninvolved sexuality, choosing an occasional man that will enable them to achieve motherhood without commitment (orangutan sex?)

Culture appeases our sexual needs, but our ancestral impulses often break free from cultural restraint and, upon sexual urge, challenge reason and unwanted pregnancies and sexually transmitted diseases ensue. Medicine needs to look at human sexuality considering both its roots and its present surroundings.

Other questions remain to be addressed. Sexual conducts, other than those socially accepted (anal coitus, cunnilingus, fellatio), sexual diversity (homosexuality and bisexuality) can be observed in monkeys as variations among species and gender distribution in the tribe. Other unacceptable social behaviors, such as incest, rape and paraphilia can also be observed in these species. Much of this, could have been carried down generations during evolution and filtered as sex became more rational and restricted by the culturalization process of the human species.

PREMATURE EJACULATION: DIAGNOSIS AND TREATMENT

ERNESTO GRASSO

(Sección Andrología / Sexología, Sanatorio Trinidad Mitre, Buenos Aires, Argentina)

Premature Ejaculatory Dysfunction is the most prevalent sexual dysfunction in the male, though consultation for erectile dysfunction occurs more often. This dysfunction affects not only the person who ejaculates prematurely, but involves his partner as well, because it does not allow both to enjoy the pleasure of sexual encounter for a longer period of time. In this symposium, I will present various definitions of premature ejaculation dysfunc-

tion which have been in use throughout the years, until the latest one, derived from a consensus organized by International Society of Sexual Medicine. I will classify premature ejaculatory dysfunction from different standpoints and address its physiopathology. I will show how the partner of such a patient is affected. I will illustrate how patients, influenced by myth and urban legend, try to solve this problem on their own. I will present different clinical cases that will help understand the suffering these patients undergo. I will show different therapeutic alternatives and, with the help of all those present, will try to choose the most adequate treatment for each case presented. In this way, I intend to show how these patients can be helped from both a biological and psychological perspective.

FROM ENDOTHELIAL DYSFUNCTION TO ERECTILE DYSFUNCTION. WHERE DO WE STAND IN 2017? THERAPEUTIC POSSIBILITIES

MIGUEL RIVERO
(Equipo de Neurocirugía Endovascular Radiología Intervencionista, Buenos Aires, Argentina)

In a vast majority of patients with Erectile Dysfunction, it is based on a biogenic process together with some psychological aspects. The two way equation 'Erectile Dysfunction vs Endothelial Dysfunction" is the key to be considered. Many illnesses and or risk factors are present around this equation, such as obesity, diabetes, hypertension, hypogonadism, ageing, lower urinary tract symptoms / beningn prostate hyperplasia, etc. One of three patients who consult about ED does not know about them. Therefore, the importance of a global approach. After the diagnosis of ED and the right management of the risk factors, the treatment could be more effective. The modern alternatives for treatment of ED, which must be personalized according to each patient, will be presented.

SEXUALITY IN MENOPAUSE

MARTA RAJTMAN
(Sociedad Argentina de Sexualidad Humana, Buenos Aires ,Argentina)

We can definitely state that for women, sexuality exists until they want it to. Neither medicine nor the psychological sciences have shown that being sexually active all life long, may be harmful or impossible to achieve. Taboos, the ban implicit in the cultural message we receive, are remnants of the belief that sexuality is only useful for reproduction and is no more licit or acceptable when it has lost its reproductive aim. Our first job is, thus, to remove from this topic the idea of forbiddance and shame.

We must be aware of the changes taking place in our body, accept them and learn to enjoy in a different way. Our sexuality will not be the same as before, but it may be excellent. The important thing is to keep active and stand up for our right to life and pleasure.

Every single aspect that has been studied in relation to menopause, has shown that there are significant changes involved, and that they limit quality of life and life expectancy of women, with high morbidity and mortality.

As important as it is for the primary care sexologist to know this process thoroughly, from all its biological, psychological and social standpoints, so it is for the patient. In this contention, it is necessary to individualize each woman and every aspect of her personality.

The menopausal woman belongs to a particular social group with a characteristic epidemiologic profile. Accordingly, she needs special medical care during this very important period of her life where, as has been previously shown and can be easily inferred, there is so much to be done in health prevention and promotion.

MYC IS A GLOBAL REGULATOR OF THE HOST IMMUNE RESPONSE

DEAN W. FELSHER
(Stanford University, Stanford, California, USA)

Many human cancers are as associated with the activation of specific oncogenes. We have used the Tet System to generate transgenic mouse models to model and predict the therapeutic efficacy of targeted therapy of specific oncogenes. We have shown that many oncogenes (MYC, RAS, BCR-ABL) induce tumorigenesis that is completely reversible upon their inactivation. Previously, we have described this phenomenon as oncogene addiction. We have shown that oncogene addiction is associated with proliferative arrest, apoptosis, differen-

tiation, cellular senescence and the shut down of angiogenesis.
Now, we have found that the oncogenes, such as MYC, casually regulates the immune response. MYC transcriptionally regulates immune checkpoint regulators, including PD-L1 and CD47 in murine and human tumor cells. MYC activation can causally suppresses an immune response against tumors. Conversely, MYC suppression, reduces expression of immune checkpoints and elicits and immune response. Finally, blocking the ability of MYC inactivation to down-regulate expression of PD-L1 or CD47 prevents tumor regression. Hence, MYC oncogene addiction is causally associated with ability to regulate immune checkponits.
MYC's regulation of immune checkpoints is causally regulates the recruitment of innate and adaptive immune effector cells that regulate tumor microenvironment. Then, these immune effectors regulate self-renewal programs in tumor cells and host angiogenesis in the tumor microenvironment. Hence, the MYC oncogene globally regulates the host immune response. Therapies that target MYC could be used to restore the immune response against human tumors. MYC overexpression may predict responsiveness to immune checkpoint therapy.

ON THE ROLE OF THE MICROBIOTA AS A KEY MODULATOR OF THE TUMOR MICROENVIRONMENT

ROMINA GOLDSZMID
(Center for Cancer Research, NCI; NIAID, National Institutes of Health, Bethesda, Maryland, USA)

Cancer has historically been viewed as a disease determined by genetic and environmental factors, however, it is now clear that inflammation affects all stages of the disease: initiation, progression and metastasis formation. The inflamed tumor microenvironment is in part sustained by infiltrating mononuclear phagocytes (MPs) [e.g. dendritic cells, monocytes, macrophages] and neutrophils. In cancer, as in infection, MPs can induce adaptive immune responses, but in cancer they mainly promote the tumor's immune evasion, progression, and metastasis. We, and others, have recently uncovered a role for commensal microbes in controlling the response of subcutaneous tumors to cancer immuno- and chemotherapy. In this presentation, we will discuss the role of the microbiota in regulating the composition and function of the myeloid cell compartment in the tumor microenvironment and the role of these cells in the response to cancer chemotherapy. Targeting MPs represents a powerful approach to manipulate the outcome of immune responses; therefore, a clear understanding of their regulation and functional organization may lead to rational novel cancer immunotherapeutic approaches.

BLOCKADE OF FOXP3 IMPROVES THE EFFICACY OF ANTITUMOR VACCINES IN EXPERIMENTAL BREAST CANCER

MARIANELA CANDOLFI
(Instituto de Investigaciones Biomédicas, CONICET, Facultad de Medicina, Universidad de Buenos Aires, Buenos Aires, Argentina)

Breast cancer is the most frequent cancer and the first cause of death by cancer in women worldwide. Immunotherapy has emerged as a powerful therapeutic approach for the treatment of many cancers. Due to the specificity of the antitumor immune response and the possibility of generating antitumor immunological memory, the field of immunotherapy has developed exponentially over the last few decades. Unfortunately, since breast tumors were traditionally thought to be poorly immunogenic, the use of immunotherapy was long considered inappropriate to treat breast cancer patients. However, a growing body of evidence indicates that immunotherapeutic strategies can benefit a larger cohort of breast cancer patients than hitherto anticipated. Mammary tumors are infiltrated with immune cells and the level of tumor infiltrating T lymphocytes positively correlates with good prognosis in breast cancer patients. However, several immunosuppressive mechanisms impair antitumor T cell responses, such as immunological checkpoints and immunosuppressive cytokines that are up-regulated in the tumor microenvironment, skewing the immune response towards Th2 and regulatory T (Treg) phenotypes. Tumor infiltrating Tregs constitute an important therapeutic target, as they suppress effector T cell function in a dose-dependent manner and have been associated with poor survival in breast cancer patients. Tregs have also been involved in the relatively low efficacy of antitumor vaccines. We found that while prophylactic antitumor dendritic cell (DC) vaccines improved the survival of murine models of breast cancer and trigger antitumor immunological memory, DC vaccines administered to mice bearing established breast tumors induce the expansion of Tregs and lack efficacy in this therapeutic setting. In order to improve the antitumor effect of DC vaccines, we used a cell penetrating peptide (P60) that inhibits Foxp3, a transcription factor required for Treg function. Treatment with P60 inhibited tumor progression and improved the therapeutic efficacy of DC vaccines in experimental breast cancer models. Monotherapy with P60 inhibited tumor growth not only in immunocompetent mice, but also in immuno-compromised tumor-bearing mice. We found that Foxp3 is expressed in human and murine breast tumor cells, in which P60 exerted a direct antitumor effect by reducing cell viability and proliferation.

P60 also inhibited IL-10 secretion in breast cancer cells that expressed Foxp3. Our findings suggest that Foxp3 blockade improves the therapeutic efficacy of DC vaccines by inhibition of Tregs and through a direct antitumor effect. This strategy could prove useful to neutralize the immunosuppressive microenvironment and to boost antitumor immunity in breast cancer.

CONTROL OF INFLAMMATION - DRIVEN LIVER TUMORIGENESIS BY ADAPTIVE IMMUNITY: A TUG OF WAR BETWEEN IMMUNOSURVEILLANCE AND IMMUNOSUPPRESSION

MICHAEL KARIN

(University of California at San Diego, San Diego, California, USA)

Chronic hepatitis caused by hypernutrition (NASH) or alcohol consumption (ASH) increases the risk of hepatocellular carcinoma (HCC), the major form of primary liver cancer and the second leading cause of cancer related death. By investigating clinical specimens a highly appropriate mouse model of NASH in which HCC development depends on ongoing oxidative stress we found that chronic liver inflammation and fibrosis results in accumulation of IgA^+ immunosuppressive plasmocytes (ISP) that express the immunoregulatory molecules PD-L1 and IL-10. By engaging PD-1, ISP induce the exhaustion of liver infiltrating $CD8^+$ T cells, some of which recognize tumor specific antigens that are expressed by HCC progenitor cells (HcPC). This allows the growth of HcPC into established HCC, a malignant progression that is even further accelerated by total $CD8^+$ T cell ablation. Conversely, genetic and pharmacological interventions that reactivate exhausted $CD8^+$ T cells and unleash their cytotoxic activity result in the regression of established HCC. These findings establish the importance of immunosurveillance in preventing liver cancer and the contribution of a specific immunosuppressive mechanism in alcohol and obesity induced HCC.

THE NICOTINIC ACETYLCHOLINE RECEPTOR AND ITS SURROUNDING LIPIDS: A LONG-STANDING RELATIONSHIP

SILVIA ANTOLLINI

(Instituto de investigaciones Bioquímicas de Bahía Blanca, CONICET, Universidad Nacional del Sur, Bahía Blanca, Argentina)

The muscle nicotinic acetylcholine receptor (AChR) is one of the key players of the post-synaptic components in neuromuscular junction. It is an integral membrane protein that belongs to the Cys-loop superfamily of ligand-gated ion channels and is composed of four subunits in a pentameric arrangement ($\alpha_2\beta\gamma\delta$ and $\alpha_2\beta\varepsilon\delta$ in embryonic and adult muscle of vertebrates, respectively). Each subunit has a large N-terminal extracellular domain, four transmembrane segments (M1-M4), a small cytoplasmic domain between M3 and M4, and a short C-terminal extracellular domain. Summing up, the AChR has two well defined structural domains: the neurotransmitter-binding site extracellular domain and the transmembrane domain containing the ion pore. Whereas the extracellular domain is the location site of agonists or different activators/inhibitors, the transmembrane region exhibits extensive contact with the surrounding lipids through structural motifs remarkably conserved along phylogenic evolution. It is known that a correct allosteric coupling between both domains is crucial for AChR function, which is strongly dependent on lipid surrounding. We have previously demonstrated that exogenous hydrophobic molecules, such as free fatty acids or steroids, disturb this coupling through the lipid-AChR interfase. It is also known that the AChR is present in high-density clusters at the top of folds in the muscle cell membrane, and that these clusters localize in heterogeneous membrane domains highly enriched in cholesterol (Chol) and sphingolipids. We studied the influence of different lipid host compositions on the distribution of purified AChR reconstituted in membrane containing Lo domains by fluorescence resonance energy transfer efficiency between the AChR intrinsic fluorescence and Laurdan or dehydroergosterol fluorescence, and by analyzing the distribution of AChR in detergent-resistant and detergent-soluble fractions (1% Triton X-100, 4°C). When the AChR was reconstituted in a brain sphingomyelin (bSM), Chol and POPC (1:1:1) model system it lacked preference for Lo domains. However, the change of bSM by 16:0-SM or 18:0-SM resulted in the preferential partitioning of AChR in Lo domains, which was not the case with 24:1 SM. Although all these SM formed Lo domains, differences in size, amount and/or lipid order of each Lo domain were observed, showing a direct correlation with the tendency of the AChR to localize in such domains. We further studied another membrane condition resulting from inducing transbilayer asymmetry. Enrichment in bSM in the external hemilayer resulted in an increase of the amount of external domains with a higher lipid order and a marked increase of AChR in these Lo domains. Other asymmet-

ric conditions were also studied. Thus, a change in the properties/size/location of Lo domains impacts on the AChR preference for this fraction, clearly indicating that membrane lipid surrounding influences both the coupling between agonist-binding and channel-gating domains and the spatial localization of the AChR in the membrane.

A METASTABLE H-BOND ZIPPER TRANSMIT INFORMATION ACROSS THE CELL MEMBRANE

LARISA CYBULSKI

(Instituto de Biología Molecular y Celular, Universidad Nacional de Rosario, Rosario, Argentina)

Transmission of information across cell membranes is an essential activity for every cell. Bacterial thermosensor DesK is a histidine-kinase endowed with a five-span transmembrane domain that detects changes in environmental temperature and controls the phosphorylation state of its cytosolic catalytic domain. The challenge for most systems is to understand the mechanistic basis of signal transmission across the cell membrane, in order to either inhibit or potentiate signaling. To address the challenge, we constructed a sensor with a single chimerical transmembrane segment that retained full sensing capability. Genetic and biophysical dissection of this minimized DesK version enabled identification of three structural determinants of thermo-detection (DOTs). Here we combine and retune these DOTs to understand their interplay, dominance and over-writing effects according to a functional hierarchy. We found that a trans-membrane zipper represents the master DOT as it forms environmentally-controlled intermolecular hydrogen bonds driving a reversible dimerization of the transmembrane domain. Changing the pattern of dimer-promoting bonds allowed us to control signal sensitivity and even promote inverse regulation. These findings enabled the reverse engineering of a synthetic sensor built upon a poly-valine scaffold to which DOTs were incorporated. Our construct retains regulated thermosensing capacity. This modular switch may be incorporated in genetic circuits to control spatio-temporal gene expression.

STRUCTURE, FUNCTION AND FRUSTRATION IN PROTEINS: A CONFLICTING ORIGAMI

DIEGO FERREIRO

(Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Buenos Aires, Argentina)

Natural protein molecules fold, move and function according to the information encoded in their energy landscapes. For most architectures, this information is still difficult to deconvolute from the linear sequence of amino acids, as the energy contributions are small, numerous and distant. Since natural proteins are a distinct set of apparently random amino acid polymers, evolution provides the basis for the loop closure of informational flow in coded polymers. Different 'teleonomic goals' converge in the evolution of protein sequences, inevitably conflicting with each other. I will present and discuss the application of statistical analysis of structural and genomic data to extract physically meaningful information about natural proteins' physiology.

CONFORMATIONAL DIVERSITY ANALYSIS REVEALS THREE FUNCTIONAL MECHANISMS IN PROTEINS

GUSTAVO PARISI

(Universidad Nacional de Quilmes, Bernal, Buenos Aires, Argentina)

Protein motions are a key feature to understand biological function. Recently, a large-scale analysis of protein conformational diversity showed a positively skewed distribution with a peak at 0.5 Å C-alpha root-mean-square-deviation (RMSD). To understand this distribution in terms of structure-function relationships, we studied a well curated and large dataset of ~5,000 proteins with experimentally determined conformational diversity. We searched for global behaviour patterns studying how structure-based features change among the available conformer population for each protein. This procedure allowed us to describe the RMSD distribution in terms of three main protein classes sharing given properties. The largest of these protein subsets (~60%), which we call rigid (average RMSD = 0.83 Å), has no disordered regions, shows low conformational diversity, the largest tunnels and smaller and buried cavities. The two additional subsets contain disordered regions, but with differential sequence composition and behaviour. Partially disordered proteins have on average 67% of their conformers with disordered regions, average RMSD = 1.1 Å, the highest number of hinges and the longest disordered regions. In contrast, malleable proteins have on average only 25% of disordered conformers and average RMSD = 1.3 Å, flexible cavities affected in size by the presence of disordered regions and show the highest diversity of cognate ligands. Proteins in each set are mostly non-homologous to each other, share no given fold class, nor functional similarity but do share features derived from their conformer population. These shared features could represent conformational mechanisms related with biological functions.

SIMPOSIA XVII
MYSTERIES OF REPRODUCTION II
Chairs: Fernanda Parborell and Maria Susana Theas

SEX UNDER THE WATER: MYSTERIES HIDDEN BY CRUSTACEAN DECAPODS

LAURA LÓPEZ GRECO
(Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Buenos Aires, Argentina)

Crustaceans represent the major group of aquatic arthropods with more than 67000 species. Decapods, commonly known as shrimps, prawns, lobsters, crayfishes and crabs (among others) comprise over 15000 species, 90% of them being marine species. The environment where the group has diversified has a profound effect in many biological aspects, including reproduction and development, moreover, the conquest of brackish, freshwater and even terrestrial habitats has modeled brooding, larvae/juveniles development and mating behavior, as much as the diversity of signals involved. In this context it is not easy to trace general statements about decapod´s reproduction, although some ideas can be pointed out. Mostly, decapods have *primary* maternal care implicated in brooding until larvae/juvenile hatching, and certain freshwater species (mainly freshwater crayfish) extend this care up to one or two post-hatching stages, known as *secondary* maternal care. The brooding is associated with modified female appendages (pleopodos) that carry the brood. In caridean shrimps there is a special molt previous to mating, *to prepare* these appendages to carry on the embryos. This is called the *nuptial molt*; whereas another particular molt, after embryos hatched females, is named *postparturial* molt. Decapods have also very unusual spermatozoa: non motile spermatozoa, and neither condensed chromatin with huge sperm cells morphotypes grouped under the terms of reptantia *versus* natantia spermatozoa, actually considered a relevant tool for taxonomy. Spermatozoa are packaged with vasa deferentia secretions forming the spermatophore/s. The form, number, time, and mechanisms of dehiscence are quite different among species, and profoundly affected by the time the spermatophore is attached to the female as well as the position in the female (internal or external to the female body). The number of packaged spermatozoa is likewise related to the number of female mature oocytes, along with planktotrophic *versus* lecithotrophic larvae. The number and size of hatched larvae (indirect development), or juveniles (direct development) is also linked with the habitat. In many decapods species, females have special morpho-functional structures for sperm storage, the seminal receptacles. They temporarily separate mating from conception, so sperm storage can be adaptive in ecologically diverse habitats, and affect life histories, mating systems, cryptic female choice, sperm competition, sexual conflict, not forgetting that it provides increased opportunity for postcopulatory sexual selection. During mating, chemical and physical signals are involved either in the rather “simple” mating systems (as many caridean species), or in the more “complex” mating systems (as many true crabs). In the more complex systems, courtship can be extended and sophisticated, spending much of the time in pre and postmating activities. This leads to a high cost of mating in some species that could be even greater than gamete production. Mating could be similarly related to somatic growth, since in many species females are recently molted at mating, while males are always in intermolt, in order to favor sperm transfer by the specialized appendages, the gonopods. Gonopods are very diverse too depending on the mode of sperm transfer. These are some of the mysteries hidden by crustacean decapods under the water, and scarcely studied.

THE MATING SYSTEM OF THE GREATER RHEA: ROLE CHANGE AND PROMISCUITY

MÓNICA MARTELLA
(Instituto de Diversidad y Ecología Animal, CONICET; Centro de Zoología Aplicada, Facultad de Ciencias Exactas Físicas y Naturales, Universidad Nacional de Córdoba, Córdoba, Argentina)

The Greater Rhea (Rhea americana) is a near threatened ratite whose wild populations are decreasing and exhibit low polymorphism levels. The mating system of this flightless bird is complex, simultaneous polygyny and serial polyandry, and very infrequent among vertebrate species, in which several females copulate with different males and lay their eggs in communal nests. The male constructs the nest, fully incubate the eggs and care for the precocial chicks. Here we evaluated the degree of relatedness among and within broods, with the aim of enlightening the reproductive system of rheas from a genetic point of view. We sampled feathers from 145 nestlings and three males that incubated in 5 nests in the wild. The genotype was determined by means of eight microsatellites developed for rheas, while relatedness was analyzed with software Colony. The study revealed that there were multiple progenitors per nest (14,8 females and 11,2 males). On average, a given female laid in 1,9 nests and produced 3,7 nestlings, while each male had descendants in 1,75 nests and produced 4,5 chicks. Two males were the major two male progenitors in the clutch they incubated (28,6% and 34,5% of the chicks were of

their own), whereas the third analyzed male had no descendants, neither in his nest nor in the other ones. Each male successfully mated 3,4 females (range: 1-8), while each female had 2,8 partners (range: 1-5). Most adults (81%) that share descendants in a nest were unrelated, and females were always less related than males. Although most full-sibs occurred within the same nest, both full and half-siblings corresponded to less than 5,5% of all paired comparisons among all chicks (complementary, 94,5% were unrelated). Our study shows that: (i) there are several progenitors of descendants in each nest; (ii) no male that incubate is the progenitor of the majority of chicks in a nest; (iii) not all incubating males leave progeny; and (iv) females do not constitute cohesive and stable groups that lay eggs in the same successively nests. This promiscuous strategy could be preventing further losses of genetic variability, counterbalancing detrimental effects that an impoverished genetic pool can exert on the viability of populations.

PREGNANCY OR LUTEOLYSIS IN RUMINANTS. EMPHASIS IN NUTRITION

ANA MEIKLE

(Universidad de la República del Uruguay, Sociedad Uruguaya de Biociencias, Montevideo, Uruguay)

The relationship between nutrition and reproduction in ruminant females has been the center of intense research. For decades, studies on the effects of undernutrition on reproductive failure have focused on central (hypothalamus-hypophysis), ovary and embryo effects. Less information has been produced about the peripheral response of the reproductive tract when nutrition is below the requirements for maintenance (e.g. situations of negative energy balance, NEB). This condition is frequent in sheep and livestock on extensive management where the pasture offer varies according to climatic fluctuations. In dairy cows, this state of undernutrition is physiologic as genetic selection towards great production volumes produces a more or less deep NEB during the peripartum. There is consensus among the international scientific community in that, even if fertilization could be affected, early embryo mortality is the main cause of low pregnancy rates in cyclic females. This embryo loss is attributed to an asynchrony between the embryo and its signals, and the uterus; a communication needed to prevent luteolysis, thus maintaining the progesterone circulating levels needed to sustain pregnancy. In this work, we present recently acquired knowledge about how nutrition affects uterine function during the early and late luteal phase, in cyclic or pregnant females, from experiments with sheep, and beef and dairy cows. It demonstrates how undernutrition to half the requirements for maintenance in sheep changes the expression level of candidate genes and proteins associated to uterine functionality and embryo growth. For instance, undernutrition reduces uterine sensitivity to progesterone (progesterone receptors), which could explain the higher rates of embryo mortality observed in undernourished animals. In the same experimental model, massive analysis of endometrial transcriptome allowed us to understand that the metabolic adaptations of the uterus to undernutrition depend on the presence of an embryo; data suggest that this tissue is able of partitioning the scarce nutrients in order to sustain an embryo. In beef cows, we have observed that nutrition in very early stages of life affects uterine function in adult females at the moment of service. In dairy cows, using candidate gene selection or RNAseq, we have demonstrated solid evidence about the impact of nutritional management during early lactation on the uterine environment at the end of the voluntary waiting period. For instance, we have found a greater expression of genes related to embryo growth and uterine function (IGF system, progesterone and adiponectin receptors) in cows fed with diets rich in energy compared to those that suffered a deep NEB in the early postpartum. Our results show that animals with worse energy balance have a uterine environment unsuitable for embryo growth, and that these mechanisms are in the base of the lower pregnancy rates.

SUCH A PRETTY TAIL…STUDYING THE SPERM FLAGELLUM BY HIGH RESOLUTION MICROSCOPY.

Dr Mariano G Buffone

Sperm acquire the ability to fertilize in the female genital tract in a process called capacitation.. During capacitation sperm undergo a change in the motility pattern called hyperactivation (HA) and acquire the ability to underog acrosomal exocytosis (AR) which are critical to fertilization.

Ca^{2+} is the primary second messenger that triggers HA motility and it depends on CatSper channels. It has been described that CatSper1 proteins form a unique pattern of four linear ‘‘stripes’’ running down the principal piece of the flagellum. Catsper Ca^{2+} domains orchestrate the timing and extent of complex phosphorylation cascades because it colocalizes with Ca^{2+} signaling molecules.

On the other hand AR is controlled by several players and one of them seems to be the actin cytoskeleton. Most studies to evaluate actin polymerization (formation of filamentous actin or F-actin) in sperm were performed using phalloidins, which are toxic and not capable of crossing the cell plasma membrane.

We have used the powerful capabilities of super-resolution microscopy to reveal the location and regulation of signaling molecules in the sperm tail and for the first time,

how are the dynamic changes in of the actin cytoskeleton at the onset of the AR. Our work also emphasizes the utility of live-cell nanoscopy for the study of sperm ultra-structures, where these imaging capabilities will undoubtedly impact the search for mechanisms that underlie basic sperm functions.

SIMPOSIA XVIII
MYOCARDIUM FROM SELF PROTECTION TO REGENERATION
Chairs. Elena Lascano and Celeste Villa Abrillet

FROM A PLURIPOTENT STEM CELL TO A CARDIOMYOCYTE: MICRORNAS AND THEIR ISOMIRS REGULATION

SANTIAGO MIRIUKA
(Instituto FLENI, Buenos Aires, Argentina)

Cell reprogramming now easily allows to de-differentiate an adult cell in to a pluripotent stem cell (PSC). These cells are then differentiated to any sort of adult cells, including cardiomyocytes (CM). These cells presents many similar features to adult CM, including spontaneous electrical beating and contractility, although protein analyses demonstrated that these cells are mostly fetal. In vitro, it is necessary to recapitulate the major steps during embryo differentiation to obtains CM from PSC, including the differentiation into mesoderm progenitor cells (MPC) through epithelial to mesenchymal transition. Different regulatory processes are involved in this differentiation, including microRNAs as one of the most important. They are short sequences of RNA of approximately 20-22 bases, including a region of 6 to 8 bases (the “seed”) in the 5’ extreme, which is able to recognize complementary sites in the 3’UTR site of mRNAs. By these recognitions, the coupled microRNA-mRNA is loaded into the RISC complex by Argonaute, which ether cleaves the mRNA or induce its degradation without translation. The key feature in this regulation is that any microRNA is able to recognize different mRNAs, and in the oposite, any mRNA may be bound by different microRNAs, and hence, the expansive network is incredible deep. Our lab works on the identification of the microRNAs during cardiac differentiation from pluripotent stem cells. We performed a small-RNA sequencing analysis of the different stages and identified those microRNAs involved in this process. We can identify two additional complexing factors: first, there are numerous isoforms (called “isomirs”) which potentially increase and expand the ability of gene regulation. Second, microRNAs can be aggregated according to sequence (“families”) or according to genome position (“clusters”). The expression pattern of microRNAs during cardiac differentiation closely follows this aggregation. Our work currently focus on the regulation of large number of microRNAs at the same time, either by using RNA sponges or by modulating cluster expression by CRISPR. Our work then contributes to the knowledge of cardiac differentiation. Fine-tuning this process is a key step in cardiac regenerative medicine

REMOTE ISCHEMIC PRECONDITIONING: PRESENT KNOWLEDGE, UNANSWERED QUESTIONS AND FUTURE PERSPECTIVES

MARTÍN DONATO
(Instituto de Fisiopatología Cardiovascular, Facultad de Medicina, Universidad de Buenos Aires, Buenos Aires, Argentina)

Ischemic heart disease is the leading cause of death worldwide. For this reason, there has been a continued search for better therapeutic strategies that would reduce myocardial ischemia/reperfusion injury. Remote ischemic preconditioning (rIPC) was first introduced in 1993 by Przyklenk et al who reported that brief regional occlusion-reperfusion episodes in one vascular bed of the heart render protection to remote myocardial tissue. Subsequently, different studies have shown that rIPC applied to the kidney, liver, mesentery artery, and skeletal muscle, all exhibited cardioprotective effects.

However, the pathway and the intracellular mechanism underlying rIPC are unknown. Thus, it has been hypothesized that communication between the signals triggered in the remote organs and protection in the target organ may be mediated through humoral factors released from the preconditioned organ and transported via the circulation (humoral pathways), by neural pathways and/or via systemic anti-inflammatory and antiapoptotic response to short ischemic bouts.

Elucidation of the mechanisms of endogenous cardioprotection triggered in the remote organ could lead to the development of diverse pharmacological rIPC mimetics. In this sense, we have shown that rIPC reduces the infarct size through a vagal pathway and a mechanism involving phosphorylation of Akt and subsequently eNOS, followed by mK^{+}_{ATP} channel opening and an increase in H_2O_2 production by the mitochondria.

In the clinical setting, rIPChas been evaluated in pediatric patients undergoing cardiac surgery and in adult patients undergoing elective abdominal aortic aneurysm repair, coronary angioplasty and coronary artery bypass

surgery. Most (but, importantly, not all) of these studies have reported attenuation of the ischemia/reperfusion injury. Despite the compelling evidence of infarct size reduction with rIPC in experimental models, the obvious appeal of exploiting this cost-effective and seemingly simple strategy to improve outcome in patients, and the promising results obtained in initial clinical studies, our knowledge of the fundamental ‘‘biology’’ of rIPC and its variants is limited. Four basic aspects of rIPC have, to date, not been elucidated. First, the choice of rIPC algorithms has been empiric: no insights have been obtained regarding the optimal remote stimulus in terms of the number of cycles of brief ischemia/reperfusion or the duration of each episode. Second, while the use of limb ischemia as the protective trigger (rather than renal or mesenteric ischemia) is undoubtedly the most practical option in terms of clinical application, there is no information as to whether the outcome is superior with arm versus leg ischemia.

rIPC and its variants hold the promise of providing a potent yet cost-effective clinical strategyt o attenuate myocardial ischemia/reperfusion injury and improve patient outcome. However, in order to achieve this potential, focused and rationally designed experiments conducted in clinically relevant models are required to (a) elucidate the ‘‘biology’’ and molecular mechanisms of rIPC, and, as a consequence (b) develop optimal rIPC algorithms for therapeutic use. A final, technical priority in facilitating the clinical application of rIPC will be the development ofc ommercial devices for the standardized administration of these optimized rIPC algorithms.

EXERCISE-INDUCED CARDIOPROTECTION: ITS PROTAGONISTS

IRENE ENNIS

(Centro de Investigaciones Cardiovasculares “Dr. Horacio Cingolani”, CONICET, Universidad Nacional de La Plata, La Plata, Argentina)

Exercise training is a consolidated approach to reduce cardiovascular morbidity and mortality. Cardiac adaptation to endurance training includes cardiomyocyte hypertrophy and improved contractility by a non-yet clarified mechanism, as the most important events. This response is mediated by the production and release of several growth factors and other humoral mediators among which, the insulin-like growth factor 1 (IGF-1) seems to be the most relevant. IGF-1 increases in response to exercise training both in experimental animal models and in athletes compared with healthy sedentary controls. Furthermore, IGF-1 has been demonstrated to be produced in cardiovascular tissue, where it likely exerts autocrine/paracrine effects. Interestingly, we have reported that exercise training is effective to convert pathological into physiological hypertrophy in the spontaneously hypertensive rats (SHR). In the pathophysiology of this consolidated experimental model of pathologic cardiac hypertrophy the hyperactivity of the myocardial Na+ /H+ exchanger-1 (NHE-1) is critical by increasing intracellular Na+ and Ca2+ concentration, hence facilitating calcineurin activation. Moreover, the hyperactivity of the NHE-1 has been extensively described as a central component of many cardiac pathologies, playing a key role in hypertrophy development and progression to heart failure. In the conversion of pathologic to physiologic cardiac hypertrophy of the SHR through exercise training/IGF-1stimulation the prevention of NHE-1 hyperactivity through an AKTdependent inhibitory phosphorylation of the cytosolic tail of the exchanger, as well as the positive inotropic and antioxidant effects, emerge as key players. With respect to the IGF- 1/exercise training enhancement in cardiac contractility we have substantial data supporting that NO-dependent CaMKII activation plays a critical role, mainly due to phospholamban phosphorylation that results in increased Ca2+ transient amplitude, rate of decay and SR content. Interestingly, this pathway (namely NO-CaMKII) seems not to contribute to the adaptive hypertrophy

ADULT CARDIOMYOCYTE CELL CYCLE MANIPULATION AS CARDIO-REGENERATIVE STRATEGY

PAOLA LOCATELLI

(Instituto de Medicina Traslacional, Trasplante y Bioingeniería, CONICET; Universidad Favaloro, Buenos Aires, Argentina)

Ischemic heart disease is the main cause of death worldwide. Cardiac ischemia results from reduced oxygen flow and nutrients to the cardiac cells. If ischemia is prolonged or intense, infarction occurs and cells die. As the rate of endogenous regeneration is slow and poorly significant, dead cells are progressively replaced by non-contractile fibrotic tissue, ultimately reducing cardiac function and leading to heart failure.The most recently released post-infarction pharmacological treatments target the neurohormonal physiology of the remaining cardiomyocytes (CMs) without intention to replenish the lost ones. So is that novel approaches for replenishing cardiomyocyteslost during myocardial infarction are in need.

An established paradigm in cardiovascular regenerative medicine is that adultmammaliancardiomyocytes have limited proliferative capacity. However, despite the low turnover rate, with most myocytes having their cell cycle blocked, they continue to increase in size and DNA content, both processes requiring cell cycle activity but not leading to cytokinesis.

To be possible for the heart to work as a sincitium, it is of vital importance that either gene or cell experimental therapies warrant newly incorporated cells' engraftment. So it is thatthere is a growing interest in identifying factors playing relevant roles in the regulation of the cell cycle,to be later used for the induction of therapeuticventricular-cardiomyocyte mitotic division.
One of the current approaches consists in the removal of the molecular brake that prevents the adult cardiomyocyte to overcome de G2/M checkpoint of the cell cycle. So far, the *meis1* gene has been identified in mice as a transcription factor required for the transcriptional activation of the inhibitor proteinsp15, p16 and p21, which inhibit cyclin-CDK complexes inducing cell cycle arrest. But more studies are needed both to confirm that this gene has a similar role in large mammals including human beings, and to find new cell cycle-regulating molecules that can be used as targets for gene therapies aimed at promoting adult cardiomyocyte cell division.
Despite the scientific progress achieved during the last decades, the goal of regenerating a damaged heart, still seems far away. While new approaches have emerged, such as the use of stem cells of different sources, bioresorbable scaffolds to improve cell retention, decellularized matrices, and gene therapies with different targets and vectors, many questions remain to be answered, including how cardiomyocyte proliferation is regulated during heart development, to reveal unknown cell cycle regulation mechanisms and regulating molecules, that can be reproduced in order to achieve myocardial regeneration. Only by unraveling the complexity of the cell cycle processes we will approach the chance of partially regenerating the human heart.

SIMPOSIA XVIII
ENDOCRINE SOCIETY JOINT SYMPOSIUM: INTEGRATING GENOMIC AND NONGENOMIC ACTION OF NUCLEAR RECEPTOR HORMONES IN PHYSIOLOGY AND PATHOLOGY
Chairs: Patricia Elizalde and Claudia Pellizas

EXTRANUCLEAR EFFECTS OF THYROID HORMONES AND ANALOGS AT THE PLASMA MEMBRANE LEVEL

SANDRA INCERPI
(Università Degli Studi Roma Tre, Roma, Italy)

Extranuclear or nongenomic effects of thyroid hormones are widely recognized, beside the classical effects mediated by nuclear receptors, suggesting the existence of different mechanisms involving plasma membrane, mitochondria, or cytoskeleton. Thyroid hormones and immune system cross-talk, although the signaling pathways of this interaction have not been defined yet. A complex relationship exists between thyroid hormone and immune system cells, and in cases of hypo- or hyperthyroidism the immune response is usually altered. Extra-nuclear effects of thyroid hormones are mainly mediated by integrin αvβ3, although other receptors also are able to elicit fast responses. THP-1 monocytes show high expression of integrin αvβ3, and are therefore a good model to study the short-term effects of thyroid hormones. Typical responses of THP-1 monocytes modulated by thyroid hormones, such as cell migration, have been studied using two different chemoattractants: Insulin-like growth factor-1 (IGF-1) and monocyte chemoattractant protein (MCP-1) a potent chemokine. Our data show that thyroid hormones, T3 and T4, in the physiological concentration range are able to inhibit the migration induced by IGF-1 and MCP-1, but the mechanisms involved appear to be different. In case of IGF-1 the inhibition by thyroid hormone depends on integrin αvβ3, and the effects are inhibited by RGD peptide, by an antibody against integrin αvβ3, and by the thyroid hormone metabolite tetrac, which also has interesting antitumor properties. In case of MCP-1-activated migration the signaling pathway elicited by thyroid hormone appears to be more complex, involving also the modulation of the redox state of the cell.

CLINICAL SYNDROMES OF GLUCOCORTICOID HYPERSENSITIVITY: GLUCOCORTICOID BETA MUTATIONS AND BEYOND

RICHARD SANTEN
(Department of Medicine, Endocrinology and Metabolism, University of Virginia, Charlottesville, Virginia, USA)

Steroid hormone action reflects the integrated effects of production and clearance rates, bioavailable plasma concentrations and receptor-mediated target tissue responsiveness. Alterations of receptor-level concentrations or biologically relevant mutations can result in relative tissue resistance or hypersensitivity. A variety of clinical syndromes are associated with glucocorticoid resistance which are caused by receptor mutations which inactivate their function. Less frequent are activating mutations which enhance sensitivity to glucocorticoids. Several mutations of the glucocorticoid receptor, including N363S, the *BCL*I restriction fragment polymorphism,

and ER22/23EK, are reported to cause hypersensitivity. Predominant clinical findings in these patients have included obesity/metabolic syndrome, hypertension, altered bone mineral density, vasoconstriction, inflammatory bowel disease, and depression.

Complex receptor systems have been described in which one receptor isoform exerts agonistic actions and another antagonistic. Under these circumstances, inactivating mutations of the antagonistic isoform would result in hypersensitivity. Specifically, with respect to the glucocorticoid receptor, Gα mediates agonistic actions and GRβ a dominant negative isoform, partially antagonizes the effects of GRα. An inactivating mutation of GRβ might then be expected to cause hypersensitivity to the action of glucocorticoids.

We have studied a patient with a compound mutation of glucocorticoid receptor β (hGR βG3134T and hGR βA3669G) with clinical findings associated with hypersensitivity. These included low morning cortisol levels over a six week period (<0.001 vs normal), an enhanced suppression of cortisol in response to dexamethasone, and development of Cushingoid features on replacement hydrocortisone. A mass spectrometry -based assay excluded surreptitious use of an exogenous glucocorticoid. Even though the cortisol levels were low, no signs of adrenal insufficiency were present and potent stimulation tests demonstrated the ability to secrete normal amounts of hydrocortisone. A series of molecular studies in transfected osteosarcoma cells (U-2 OS) demonstrated normal levels of α and β glucocorticoid receptor levels and exaggerated responses of glucocorticoid responsive genes such as GILZ. Comparison of gene expression profiles revealed that the mutant cell line had an altered profile after hydrocortisone stimulation. Studies in the patient's cells are ongoing with preliminary data supporting our findings.

In this presentation, we will review the studies of the glucocorticoid α activating mutations and their clinical manifestations and the studies in our prismatic case of glucocorticoid hypersensitivity due to compound GR β mutations. Taken together, these findings illustrate the complexity of glucocorticoid regulation and diverse clinical manifestations.

CELL TYPE SPECIFIC ACTIONS OF GLUCOCORTICOIDS *IN VIVO*: LESSONS FROM GENETICALLY MODIFIED ANIMALS

JOHN CIDLOWSKI

(Laboratory of Signal Transduction, National Institutes of Health, Bethesda, Maryland, USA

Heart failure is one of the leading causes of death in the Western world, and stress is increasingly associated with adverse cardiac outcomes. Glucocorticoids are primary stress hormones that regulate homeostasis through two closely related nuclear receptors, the glucocorticoid receptor (GR) and mineralocorticoid receptor (MR). Cardiomyocytes express both receptors but little is known concerning their coordinated actions in heart physiology and pathology. Here, we show that patients with failing hearts display a disparity in the relative levels of GR and MR compared to non-failing donor hearts. To examine the *in vivo* function of glucocorticoid signaling in the heart, we generated mice with cardiomyocyte-specific deletion of GR (cardioGRKO), MR (cardioMRKO), or both GR and MR (cardioGRMRdKO). The cardioMRKO mice exhibited normal heart function whereas the cardioGRKO mice spontaneously developed cardiac hypertrophy and left ventricular systolic dysfunction. Surprisingly, the cardioGRMRdKO mice were protected from cardiac disease, despite having pathological gene changes that were present in the GR deficient hearts. Genome-wide microarray analysis identified a set of cardioprotective gene changes that occurred uniquely in the double knockout hearts. Re-installation of MR into the cardioGRMRdKO hearts by adeno-associated virus gene transfer completely reversed the cardioprotective gene changes and resulted in cardiac dysfunction. These findings reveal not only a deleterious role for cardiac MR signaling when unopposed by GR but also the molecular targets of MR that contribute to cardiac pathology. Therapies that shift the balance of cardiomyocyte glucocorticoid signaling to favor more GR and less MR activity may provide an improved approach for treating heart disease.

PROGESTERONE RECEPTOR AS A TRANSCRIPTIONAL REPRESSOR REGULATES BREAST CANCER GROWTH

CECILIA PROIETTI

(Instituto de Biología y Medicina Experimental, CONICET, Buenos Aires, Argentina)

Progesterone receptor (PR) is a critical mediator of mammary gland development and contributes to breast cancer progression. In its classical mechanism of action PR associates with specific progesterone response elements (PREs) on chromatin. DNA-bound PR recruits transcriptional coactivators and associated cofactors, which modify the local chromatin structure and facilitate transcriptional activation, resulting in activation or repression of PR target genes. PR may also alter gene expression nonclassically, where the receptor tethers to other transcription factors bound to DNA. In addition to its direct transcriptional effects, PR activates signal

transduction pathways in breast cancer cells through a rapid or nongenomic mechanism. PR transcriptional outcome is affected by complex interactions between PR and other regulatory factors which results in different PR cistromes. Till present more attention and study has been devoted to gene activation compared to gene repression mediated by hormones, in particular, progestins. In fact, gene repression is poorly understood, with some authors even considering repression as a secondary effect of activation. In the present study, we addressed a poorly explored PR function: its capacity to repress gene expression.

In this study, we demonstrate that progestin-activated progesterone receptor reduces the expression of the master transcription factor GATA3. GATA3 is involved in mammary gland development and is crucial for the maintenance of the differentiated status of luminal epithelial cells. The role of GATA3 in breast cancer as a tumor suppressor has been established, although insights into the mechanism of GATA3 expression loss are still required.

In the present work, we show that ligand-activated PR modulates GATA3 expression through regulation at the transcriptional and post-translational levels in breast cancer cells. In the former mechanism, the histone methyltransferase enhancer of zeste homolog 2 is co-recruited with activated PR to a putative progesterone response element in the GATA3 proximal promoter, increasing H3K27me3 levels and inducing chromatin compaction, resulting in decreased GATA3 mRNA levels. This transcriptional regulation is coupled with increased GATA3 protein turnover through progestin-induced GATA3 phosphorylation at serine 308 followed by 26S proteasome-mediated degradation. Both molecular mechanisms converge to accomplish decreased GATA3 expression levels in breast cancer cells upon PR activation. In addition, we demonstrate that decreased GATA3 levels are required for progestin-induced upregulation of cyclin A2, which mediates the G1 to S phase transition of the cell cycle and was reported to be associated with poor prognosis in breast cancer. Finally, we show that downregulation of GATA3 is required for progestin stimulation of both *in vitro* cell proliferation and *in vivo* tumor growth.

SIMPOSIA XIX
INFECTION AND IMMUNITY
Chairs: Maria Silvia Di Genaro and Marisa Fernandez

RESIDENT MEMORY T CELLS

DAVID MASOPUST
(Center for Immunology, University of Minnesota, Minneapolis, Minnesota, USA)

Memory CD8 T cells protect against viral pathogens by scanning host cell surfaces, thus infection detection rates depend on memory cell number, migration, and distribution. This talk will discuss several issues related to T cell immunosurveillance efficiency including quantitative analysis of memory T cell subsets, prime boost vaccinations, evaluation of T cell migration, and in vivo imaging of virus specific CD8 T cell mediated immunosurveillance and reactivation in mucosal tissues. The talk will emphasize antiviral resident memory T cells, and will present ongoing investigations into the ontogeny and function of this lineage.

THE ART OF CO-EXISTING: IMMUNE ADAPTATIONS DURING CHRONIC INFECTIONS

ELINA ZÚÑIGA
(Division of Biological Sciences, University of California at San Diego, San Diego, California, USA)

During chronic infections, long-term cell adaptation via functional exhaustion has been mostly studied in T cells and B cells but much less is known on how (typically short-lived) innate cells adjust to a persistently infectious milieu. To address this question we studied Plasmacytoid Dendritic Cells (pDCs), which specialize in Type I Interferon (IFN-I) production but often become functionally exhausted in persistent infections and tumors. Our work uncovered novel aspects on the basic regulation of IFN-I producing cells and could have implications for therapeutically manipulating innate responses during chronic diseases. Furthermore, the new knowledge gather from these studies provides a framework to understand how the innate immune system adapts to co-exist with a persistently replicating pathogen for the life of the host.

ZIKA VIRUS CONGENITAL SYNDROME IN EXPERIMENTAL MODELS

JEAN P. SCHATZMANN-PERON
(Instituto de Ciencias Biomédicas, Universidade de Sao Paulo, Sao Paulo, Brazil)

Brazil has recently gone through an unprecedented public health crisis due to the Zika virus epidemics. As many other flavivirus it has never been correlated with human morbidity or mortality. Unfortunately it has changed dramatically as the virus is now responsible for more than 2300 babies born with microcephaly. The so-called Zika Congenital Syndrome has, besides microcephaly, many other relevant features, as retinal damage, intra-uterine growth restriction and arthrogryposis. In fact, babies born without microcephaly but with significant neuronal and retinal lesions have also been reported. In this context, the development of an experimental model is of great relevance for the studies on the pathogenesis of microcephaly. We demonstrated that the infection of pregnant SJL mice with ZIKV results in severe damage of the pups. Most prominently was the significant reduction in size and weight associated with high viral titers in the brains. This was accompanied by high level of apoptotic cell death, probably of neuronal precursor cells (NPCs). In order to confirm this we infected NPCs and human brain organoids with ZIKV, and observed a significant reduction on the number of NPCs, corroborating the apoptotic cell death hypothesis. Currently we are focused on several aspects of the brain inflammation during microcephaly. Interestingly, many pro-inflammatory cytokines are down-regulated, as well as viral receptors and signaling transduction molecules. This is consistent with clinical findings, showing no sign of inflammation, at least through cerebrospinal fluid protein and cellular analysis. This may indicate that the virus controls inflammation in situ. The elucidation of such mechanism would greatly contribute for the understanding of the viral biology in the central nervous system and also for the pathogenesis of microcephaly.

GLYCAN- AND PEPTIDE-BASED VACCINES PROTECT AGAINST HEART INFLAMMATION AND PARASITE BURDEN IN THE NONHUMAN PRIMATE MODEL OF CHAGAS DISEASE

IGOR ALMEIDA

(University of Texas, El Paso, Texas, USA)

Chagas disease (ChD) is a devastating neglected tropical illness caused by the protozoan *Trypanosoma cruzi,* currently affecting 6-8 million people. There is no vaccine available to prevent or treat ChD. *T. cruzi* has a plasma membrane coated by highly immunogenic glycosylphosphatidylinositol (GPI)-anchored glycoproteins, such as mucins and mucin-associated surface proteins (MASPs). Mucins contain the immunodominant glycotope, Galα(1,3)Galβ(1,4)GlcNAcα (KM24), which induces high levels of lytic, protective anti-α-Gal antibodies, which control the parasitemia in both acute and chronic phases of the disease. Recently, we showed that Galα3LN covalently coupled to a carrier protein elicited 100% survival upon parasite challenge in the **α**-galactosyltransferase-knockout (αGalT-KO) mouse model, which mimics the human response against αGal-containing epitopes. MASPs encompass overlapping B- and T-cell epitopes in a peptide named MASPpep (DAENPGGEVFNDNKKGLSRV), which was recently revealed by proteomics of trypomastigote extracellular vesicles and immunoinformatics and shown to induce considerable protection against *T. cruzi* challenge. Here, we evaluated the efficacy of KM24 and MASPpep as potential ChD vaccine candidates in a nonhuman primate model. Four groups of *Papio hamadryas* (baboons; 4 animals each), were immunized subcutaneously with KM24 covalently linked to HSA (KM24h), MASPpep covalently linked to KLH (MASPpep□KLH), KM24h+MASPpep-KLH, or PBS (placebo); all containing liposomal-monophosphoryl lipid A (L-MPLA) as an adjuvant. All groups were immunized four times at weeks 0, 6, 12 and 24, and challenged twice with metacyclic trypomastigotes (isolate HC123, TcI, originated from baboons). Blood, serum, and heart samples were collected for analysis of specific antibody titers (by CL-ELISA), parasite burden (by qPCR), serum and heart cytokines (by Multiplex), and heart histopathology, inflammation-related microRNAs, and metabolomics. We observed a very strong antigen-specific antibody response in immunized baboons with either vaccine alone or combined. Additionally, histopathology and parasite load evaluation of vaccinated baboon hearts clearly indicated that both vaccines, alone or combined, elicited significant protection against inflammation and parasite burden in the cardiac tissue, hallmarks of chronic ChD. Analysis of inflammation-related microRNAs, cytokines, and metabolites in cardiac tissues are underway and will be discussed.

SIMPOSIA XX
BIOLOGY OF LIPIDS IN REGULATING CELL PHYSIOLOGY

THE PHASE OF FAT: MECHANISMS AND PHYSIOLOGY OF LIPID STORAGE

TOBIAS WALTHER

(Harvard Medical School, Harvard University, Boston, Massachusetts, USA)

All organisms face fluctuations in the availability and need for metabolic energy. To buffer these fluctuations, cells use neutral lipids, such as triglycerides, as energy stores. We study how lipids are stored as neutral lipids in

cytosolic lipid droplet organelles. Specifically, we investigate the molecular processes that govern the synthesis of energy storage lipids as well as their storage in and mobilization from lipid droplets. In modern societies, individuals often face metabolic energy excess, leading to metabolic diseases. We will present our studies on the causal link between energy excess and metabolic disease.

METABOLIC RHYTHMS PERSIST IN PROLIFERATIVE GLIOBLASTOMA CANCER CELLS WITH AN ALTERED CIRCADIAN TRANSCRIPTIONAL CLOCK

MARIO GUIDO

(Centro de Investigaciones en Química Biológica de Córdoba, CONICET; Facultad de Ciencias Químicas, Universidad Nacional de Córdoba, Córdoba, Argentina)

Circadian clocks distributed all throughout the body and present in immortalized cell lines temporarily regulate physiological processes, driving molecular rhythms in gene expression through a transcription/translation feedback loop (TTFL); however, metabolic/redox cycles can persist without transcription in a number of different cell types; they are highly conserved through evolution and present in all kingdoms of life. A body of recent evidence suggests now that under physiological situations the cellular clock can be made up of both the TTFL- and the metabolic oscillators working together and interacting to temporally control physiology. The disruption of circadian rhythms as a consequence of modern life (shiftwork, jetlag, etc.) and continuous artificial illumination conditions may lead to metabolic syndrome and higher cancer risk. Since carcinogenesis is a complex process resulting in the deregulation of cell growth and division, here we investigated whether immortalized human glioblastoma cells maintained quiescent or under proliferation keep a functional cellular clock after synchronization and whether proliferating cells display differential time responses to drug treatment. We examined the expression of key components of the canonical molecular clock (*Bmal1, Per1, Rev-erbα),* and of glycerophospholipid (GPL) synthesizing enzyme genes (*choline kinase α: Chokα* and *CTP:phosphoethanolamine cytidylyltransferase 2:Pcyt-2*), as well as redox metabolism, peroxiredoxin oxidation cycles, GPL-endogenous content and metabolic ^{32}P-GPL labeling over time. Cells grown in 10% FBS-DMEM were synchronized with dexamethasone (DEX, 100 nM) for 20 min (time 0), maintained with (proliferative) or without (arrested) FBS-DMEM for 36-48 h and collected at different times for further assays. In arrested cultures *Bmal1*, *Per1, Rev-erbα, Chokα* and *Pcyt-2* mRNAs and the labeling of ^{32}P-GPLs exhibited a circadian rhythmicity after synchronization. Temporal oscillations were also found in the redox state, and peroxiredoxin oxidation cycles. In proliferating T98G cells, the circadian-controlled rhythmicity of gene expression was lost or its periodicity shortened whereas the redox state and GPL metabolism continued to fluctuate with a similar periodicity to that observed under arrest or over a longer period. Moreover, under proliferation the viability of cells significantly changed over time after treatment with the proteasome inhibitor bortezomib (500 nM), a potent chemotherapeutic agent. With this procedure, the highest levels of cell death (70%) are achieved from 12 h up to 24 h after DEX synchronization compared with only ~50% cell death at other times. Results strongly suggest that an intrinsic cellular metabolic oscillator operates in proliferating tumor cells regardless of the transcriptional circadian clock rhythmicity; the persistence of such temporal control of metabolism likely reflects differential tumor cell suitability for a more efficient, time-dependent drug treatment to be applied at those times at which the cellular redox state is high and GPL metabolism is low.

DECIPHERING MYCOBACTERIAL LIPID BIOSYNTHESIS REGULATION

GABRIELA GAGO

(Instituto de Biología Molecular y Celular de Rosario, Rosario, Argentina)

Besides the relevance of lipid derived molecules in *M. tuberculosis* pathogenicity, little is known about the environmental signals and regulatory cascades involved in the global regulation of lipid metabolism in this bacterium and how lipid homeostasis is maintained for survival and during infection. Our work is directed to fulfill some of these gaps by studying in detail the elements and mechanisms that regulate lipid homeostasis in *M. tuberculosis*, how they impact in the biosynthesis and composition of its cell wall and how host-pathogen lipid metabolisms interact. Mycobacteria are unusual in possessing two fatty acid synthase (FAS) systems, the eukaryotic-like FAS I and the prokaryotic-like FAS II. We initiated our research project with the identification and characterization of the components of the transcriptional regulation network that keeps these two systems tightly regulated and found they were essential for survival. We have constructed and analyzed several conditional mutants in the components identified. The results obtained using lipidomic, proteomic and transcriptomic studies helped us to not only comprehend the physiology and physiopathology of this harmful pathogen but also to identify new targets that can be used for the screening of new antimycobacterial compounds.

A SCIENTIFIC JOURNEY FROM THE BRAIN TO THE RETINA LED BY ISOPRENOIDS AND PROTEIN PRENYLATION

ELENA POSSE DE CHAVES

(University of Alberta, Edmonton, Canada)

Autophagy is a process of lysosome-mediated degradation of cytoplasmic cargos. Small GTPases Rabs, the well-known regulators of membrane trafficking, play key roles in autophagy. Rabs anchoring to cell membranes is achieved by prenylation and is essential for activation of their biological function. Prenylation is the post-translational modification of proteins by covalent attachment of the isoprenoids farnesyl-pyrophosphate or geranylgeranyl-pyrophosphate (GGPP).

We found that when Rab prenylation is defective autophagy flux is significantly impaired. I will present data from two experimental settings.

In Alzheimer's disease (AD) autophagy is dysfunctional and reversing autophagy dysfunction in animal models improves the pathophysiology and rescues memory. Yet, the nature and cause(s) of autophagy dysfunction in AD are unclear, which prevents the development of disease-modifying strategies targeting autophagy. We discovered that amyloid beta peptide (oAβ42) inhibits isoprenoids synthesis decreasing protein prenylation in cultured cells and in brains of the AD mouse model TgCRND8. Using the reporter mCherry-GFP-LC3 in neurons treated with Aβ and in vivo, we found that autophagic flux is blocked. We tested the ability of GGPP to normalize autophagic flux and Rab7 function. Rab7 is required for autophagy progression. In Aβ-treated neurons, Rab7 is hypoprenylated and its localization to autophagosomes is reduced. GGPP prevented Aβ-induced autophagy dysfunction and corrected Rab7 prenylation and Rab7 subcellular localization. Thus, our data indicate that autophagy defects in AD are due, at least in part, to inhibition of protein prenylation secondary to decreased isoprenoids synthesis. Restoration of protein prenylation in cultured cells normalizes autophagy and in vivo could improve the pathophysiology of AD.

Several prenylated proteins are required for normal retinal function and if mutated they cause inherited retinal diseases. We tested the effect of protein prenylation inhibition by statins in a cell model of retinal pigmented epithelium (REP). Simvastatin impaired LC3-Associated Phagocytosis a type of selective autophagy that mediates degradation of photoreceptor outer segments. GGPP prevented inhibition of protein prenylation by statins and corrected photoreceptor phagocytosis. We also examined the effect of simvastatin on retina function in vivo in mice subjected to chronic treatments with simvastatin. Retina function was assessed by electroretinogram recording. At the end of the study we performed biochemical (cholesterol mass, RTPCR of hydroxymetylglutarylcoA reductase, protein prenylation) and histological analysis of the neural retina and the RPE. Simvastatin treatment was associated to impaired retinal signal transmission. Moreover, cryosections of simvastatin-treated mice retinas showed bipolar cells sprouting, a previously reported potential compensatory mechanism in response to reduced photoreceptoral pre-synaptic modulation. RPE flat mounts of simvastatin-treated mice showed the presence of larger RPE cells, a feature observed in retinal degenerative diseases upon RPE cell loss. Levels of plasma and retinal cholesterol mass did not differ between treated and untreated mice. Our experiments suggest that simvastatin treatment might have detrimental effects on retinal function. This may constitute a possible side effect common to all statins and could be particularly relevant to patients with pre-existing retinal diseases.

Our studies identify protein prenylation as a pivotal process for normal autophagy function and highlight its importance in several physiological and pathological paradigms.

SYNAPTOPATHIES: PRE-PRODROMIC STAGES OF NEUROPSYCHIATRIC DISEASE?

FRANCISCO BARRANTES

(Instituto de Investigaciones Biomédicas, CONICET; Universidad Católica Argentina, Buenos Aires, Argentina)

Classical views on the neuropathology of neurodegenerative diseases such as Alzheimer disease and Parkinson disease have relied on the assumption that the alterations of neuronal cell bodies (intracellular protein accumulation) and the accretion of metabolic extracellular deposits constitute the initial pathological events. Current views, however, suggest that early alterations of the structure and function of brain synapses play a major role in the pre-symptomatic stages of neurological and neuropsychiatric diseases, certainly before major clinical manifestations are made apparent, and probably before the occurrence of neuronal degeneration and death. Dysregulation of synaptic structure and function, encompassed under the term "synaptopathies", may not only be early aspects of Alzheimer and Parkinson diseases, but also include schizophrenia spectrum and autism spec-

trum disorders, addictions, and depression syndromes. Synaptopathies comprise a wide range of phenotypes, from alterations in the number or size or the dendritic spines, dysmorphic or disarranged spine localization along the dendritic arborizations, biochemical alterations, and combinations thereof. I will review the state-of-the-art knowledge on synaptopathies acquired with the help of current research tools, with special emphasis on superresolution imaging techniques.

STUDY OF NEUROINFLAMMATION TO IDENTIFY NEUROPROTECTIVE TARGETS FOR PARKINSON´S DISEASE

FERNANDO PITOSSI
(Fundación Instituto Leloir, CONICET, Buenos Aires, Argentina)

Parkinson ´s Disease (PD) is the second most common neurodegenerative disease in the population. One patho-physiological feature consistently found in animal models and PD patients is robust microglial activation. Identifying parameters that could determine a univocal role of microglial activation on neuronal cell death in the substantia nigra (SN), the main region affected in PD, is crucial to define new therapeutic targets against PD and select PD patients to be enrolled in anti-PD trials based on immunomodulation.

We have found that microglial activation in the degenerating SN is “primed”. Microglial cells can be shifted to a pro-inflammatory state by central and also sub toxic levels of systemic inflammation. This shift can dramatically exacerbate on-going neurodegeneration in the SN leading to increased and earlier motor symptoms, via Interleukin-1beta (IL-1) overproduction. In addition, we have observed that sustained but not acute expression of IL-1 or Tumor necrosis factor-alpha (TNF) in the SN leads to dopaminergic neuronal demise, motor symptoms and microglial activation. TNF effects are dose-dependent since, using a combination of knock-in mice, adenoviral vectors and the CRE/lox system we could demonstrate that low levels of TNF can be neuroprotective for nigral neurons, while higher levels could be detrimental.

In conclusion, we have identified parameters that determine a given effect of pro-inflammatory cytokines on neuronal viability and generated several inflammation-mediated models of nigral degeneration and motor symptoms that could be exacerbated systemically. In addition, these models could serve for the identification of inflammation-derived specific molecules with univocal toxic or protective effects could serve as future protective treatments against PD.

DRUG DISCOVERY IN PSYCHIATRY: FROM GENES TO TARGETS, CIRCUITS AND PATIENTS

PATRICIO O´DONNELL
(Harvard Medical School, Harvard University, Boston, Massachusetts, USA)

Despite strong recent advances in our understanding of brain circuits underlying psychiatric disorders, there has been a paucity of novel drugs entering the market. How can we move forward and take advantage of the wealth of human and animal data that can help the field? A reasonable starting point to identify novel targets is human genetics. However, as the genetic contribution to neuropsychiatric disorders is non-Mendelian, this will not be a straightforward effort. Patricio O’Donnell will provide an overview of the strategy adopted at the Pfizer and other companies to identify and validate novel targets for Psychiatry. Specifically, we started with the recent genomewide association studies (GWAS) for schizophrenia, in which 108 loci were identified as conferring risk for the disorder (Rikpe et al, Nature 2014). We established a workflow that allowed identifying the most likely gene driving the association in most of the 108 loci using linkage disequilibrium analysis. Then, we set an iterative process of selecting a short list of genes in which we considered factors such as whether the GWAS loci were in coding regions of the genome, the potential directionality of the effects, the relevance of these genes to known pathophysiological processes, and the link to testable and targetable biological processes (Schubert et al, Neuron 2015). We identified some transcription factors (ZNF804A), Calcium channels (L and T type), cellular signaling (AKT/GSK3beta) and cell transporters (SLC39A8, a zinc transporter). We followed this up with setting up cell lines and mouse models in which these genes were knocked down and tested the impact on circuitry and function using electrophysiology. One example of how this line of research could contribute to novel pharmacological tools is the AKT signaling. As a consequence of the GWAS data, we explored novel dopamine pharmacology that takes advantage of beta-arrestin signaling (which signals through AKT and GSK3beta). A handful of beta arrestin biased compounds were developed and tested in animal models relevant to psychiatric conditions. These agents showed an antipsychotic like profile, along with cognitive benefits. Electrophysiologi-

cal data revealed that biased dopamine pharmacology was beneficial for restoring activity of cortical inhibitory interneurons (Urs, PNAS 2016). Thus, the use of genetics as a starting point for psychiatry drug discovery may open the door to novel targets and a more biologically informed drug discovery process.

TAUOPATHIES: PERSPECTIVES ON AN EMERGING PATHOBIOLOGY

KENNETH KOSIK
(University of California at Santa Barbara, Santa Barbara, California, USA)

In several neurodegenerative diseases including Alzheimer disease, tau self-assembles into intracellular aggregates of fibrous polymers. The mechanism by which this critical transition from a soluble protein to an insoluble fibrous state occurs is unknown. We have discovered that tau molecules can become compacted into a protein-rich droplet while maintaining their solubility and native-like protein conformations. This dense liquid droplet state is termed a complex coacervate, and it is held together by the opposite charges of their constituents, ions, and water. In the case of the tau protein, the opposite charge comes from RNA. In human neuronal cell culture, tau selectively binds to a category of RNA known as tRNA. Tau and RNA favorably condense under physiologic conditions to a complex coacervate phase. When the tau-RNA–dense droplets are incubated together over time, tau transitions to a conformation similar to that found in pathological fibers. Current directions include the detection of liquid-liquid phase separated states that incorporate tau in living cells. Additional studies have uncovered an upstream tau pathway that can detect mutant tau before aggregates occur. A repurposed drug to prevent tau inclusions in a mouse model can favorably regulate this pathway.

CROSSING BORDERS WITHOUT A VISA: HOW DO AFRICAN TRYPANOSOMES COLONISE THE TSE-TSE FLY VECTOR?

ÁLVARO F. ACOSTA-SERRANO
(Parasitology and Vector Biology Department, Liverpool School of Tropical Medicine, Liverpool, United Kingdom)

Trypanosoma brucei undergoes a complex life cycle within the tsetse vector, which involves migration and colonization of different fly tissues. Establishment of a trypanosome infection occurs after the parasites reach the ectoperitrophic space (ES), which is in direct contact with the gut epithelium and is separated from the lumen by the 3-layered peritrophic matrix (PM). Although unproven, the most widely accepted hypothesis on how *T. brucei* reaches the ES is by direct crossing of the tsetse PM. However, PM degradation by trypanosomes is unlikely considering that this is a chitin-rich tissue and *T. brucei* lacks chitinase activity. Furthermore, while previous microscopy experiments show trypanosomes confined between PM layers, evidence of degradation from the midgut lumen or towards the ES have so far been elusive. We re-studied this event by a combination of 3D-fluorescent and -electron microscopy. We found no evidence supporting PM degradation by trypanosomes. Instead, we discovered that trypanosomes invade the ES via the proventriculus (PV - point of PM synthesis), a process that also accounts for the formation of “parasite pockets”, which are then carried along the entire length of the gut as the PM gets synthetized. We propose that after the fly takes an infected bloodmeal, trypanosomes first enter the ES via the PV, which is crucial to establish a midgut infection.

FROM METACYCLICS TO RETROMONADS: A NEW STAGE IN *LEISHMANIA* DEVELOPMENT WITHIN THE SAND FLY MIDGUT IMPACTS VECTORIAL CAPACITY

JESUS VALENZUELA
(Laboratory of Malaria and Vector Research, National Institutes of Health, Rockville, Maryland, USA)

Leishmania parasites undergo several developmental stages that give rise to infectious metacyclics, forms adapted for transmission to mammalian hosts. To date, metacyclics have been considered as a final terminally differentiated stage in the sand fly midgut. Here, we reveal a hidden developmental cycle that drives continued augmentation of metacyclics within an infected fly. Blood causes *Leishmania* metacyclics to **dedifferentiate** into a replicative leptomonad-like stage within the thoracic anterior midgut in a process we refer to as **reverse metacyclogenesis.** This newly observed phenomenon resets the infection inside the vector significantly increasing the

number and homogeneity of the parasites through additional rounds of multiplication prior to redifferentiating back to metacyclics. Moreover, haptomonad promastigotes significantly increase in number forming a larger and more distinct spheroid structure, the **haptomonad plug**, that physically blocks the stomodeal valve further promoting transmission. The effect of taking a subsequent blood meal after acquiring *Leishmania* parasites is equally critical for early infections. Our data shows that only a median of 52 (*L. longipalpis*) and 80 (*P. papatasi*) parasites are taken up by a sand fly naturally feeding on an infected host. In the absence of a second blood meal, the large majority of infections are poor or lost. In contrast, the majority of flies that obtain another blood meal 6 days after infection, as they would naturally, develop transmissible infections. Together, our data reveal the critical role of multiple bloodmeals in *Leishmania* development within sand flies that extends beyond metacyclics to expose novel cycles of parasite amplification that enhances vector infectivity with every blood meal.

MULTIPLE ROLES OF MITOCHONDRIA IN INFLAMMATORY CHAGASIC CARDIOMYOPATHY

NISHA GARG

(Department of Microbiology and Immunology, University of Texas Medical Branch, Galveston, Texas, USA)

Chagas disease represents the third greatest tropical disease burden globally, and accounts for ~$8 billion US dollars costs annually in patient care. No vaccines or safe drugs are available for treatment of an estimated >300,000 patients in the US and >20 million patients in endemic countries. Our lab focuses on studying the utility of FDA approved drugs in providing cardioprotection from the severity of progressive cardiomyopathy and ischemic cardiac injury, and set a new direction for clinical treatment of Chagas disease.

Our published data suggest the mitochondrial dysfunction in the heart is linked to suppressed antioxidant response and inflammation-induced immunopathology, particularly due to reactive oxygen intermediates. So far no mechanisms are known as to how these pathways converge to cause clinically symptomatic Chagas disease. In recent studies, we have tested the hypothesis that *activation of cGMP/PKG and SIRT1/PGC1 signal transduction networks will preserve the antioxidant response and mitochondrial function and prevent the oxidative/inflammatory adducts that precipitate cardiomyocytes death and cardiac remodeling in Chagasic disease*. For this, C57BL/6 mice were infected with *T. cruzi* and at the end of acute parasitemia (i.e. 45 days post-infection), treated with sildenafil that inhibits PDE5 (negative regulator of cGMP/PKG) or SRT1720 (SIRT1 agonist) twice per week for 3 weeks. Mice were monitored at 150 days post-infection corresponding to chronic disease phase. The cGMP/PKG and SIRT1 activities were decreased by 2-fold in chagasic myocardium. Transthoracic echocardiography showed the left ventricular (LV) systolic function, i.e., stroke volume, cardiac output, and ejection fraction, were significantly decreased in chagasic mice. Inhibition of PDE5 or activation of SIRT1 preserved the LV function in chagasic mice. The cardioprotective effects of PDE5 antagonist were provided through improvement of mitochondrial health and function, antioxidant/oxidant balance, and inhibition of cardiac collagenosis and chronic inflammation that otherwise were pronounced in chagasic myocardium. The cardioprotective effects of SIRT1 agonist were primarily provided through control of chronic inflammation.

We will discuss the mechanistic links between cGMP/PKG and SIRT1/PGC1 signal transduction networks in providing protection from mitochondrial and inflammatory stress in Chagas disease.

TOXOPLASMA GONDII MOLECULAR MIMICRY: FROM IMMUNE EVASION TO PARASITE PERSISTENCE

HAKIMI MOHAMED-ALI

(Institute for Advanced Biosciences, Université Grenoble Alpes, Grenoble, France)

The obligate intracellular parasite *Toxoplasma gondii* strikes a subtle balance with the host immune system that not only prevents host death but also promotes parasite persistence. Although being enclosed within a parasitophorous vacuole (PV), the parasite actively interfaces with host cell signaling pathways, thereby directing host cell responses. The PV membrane has been regarded as a sieve limiting the delivery of proteins secreted by the parasite beyond the vacuolar space. However, the discovery of a large variety of effector proteins originating from dense granule organelles (GRA proteins) and their remarkable ability to cross the PV membrane and to accumulate in the host cell nucleus has changed this paradigm. With this new repertoire of molecular weapons, it can target gene expression at both the transcriptional and posttranscriptional levels by regulating the amount of mRNAs encoding proteins and affecting noncoding RNAs, e.g., microRNAs, respectively. These effectors highlight novel mechanisms by which *T. gondii* has learned to harness host signaling to favor intracellular survival and will guide future studies designed to uncover the additional complexity of this intricate host-pathogen interaction.

THE SPARC PROTEIN IN LIVER DISEASE. A NOVEL THERAPEUTIC TARGET?

GUILLERMO MAZZOLINI RIZZO
(Instituto de Investigaciones en Medicina Traslacional, CONICET, Universidad Austral, Buenos Aires, Argentina)

Secreted protein acidic and rich in cysteine (SPARC), also called osteonectin, is a 43-kDa glycoprotein highly conserved among different species. SPARC is secreted into the extracellular matrix (ECM), and although it has no structural function SPARC facilitates cell-cell and cell-ECM interactions . SPARC is expressed during tissue development, in tissues with high ECM turnover and in injured tissues. A receptor for SPARC was not identified yet, however, the binding of leukocyte-derived SPARC to VCAM-1 was demonstrated to be necessary for leukocyte transmigration through endothelial monolayers in vitro. It has also been observed that SPARC binds to integrin beta 1 and that this interaction enhances integrin-linked kinase activation and pro-survival activity. In normal livers, SPARC is slightly expressed in some spindle-shaped cells located in periportal areas and in scarce sinusoidal cells within the lobule. Expression of SPARC in normal hepatocytes was not clearly observed. Our group has been involved in the study of the role of SPARC in liver diseases for many years. We have observed that SPARC expression levels were increased in liver samples from patients and animals with acute liver failure (ALF). In SPARC knockout (SPARC-/-) mice a decreased hepatic damage was observed in different ALF animals models (e.g. Concanavalin A, LPS, APAP). Mechanisms of protection involved resistance of liver sinusoidal endothelial cells damage and reduced ROS induction. Inhibition of SPARC by siRNA administration reduced the degree of liver damage in mice.

On the other hand, the role of SPARC in hepatic fibrosis has been particularly investigated in our laboratory. We observed that SPARC knockdown protects mice against the damage induced by chronic intoxication with thioacetamide (TAA). By using an adenovirus encoding for an antisense against SPARC mRNA (AdasSPARC), in a TAA-induced liver fibrosis model in rat, we were able to reduce the amount of liver damage and the number of hepatic stellate cells (HSC), a key cell population involved in hepatic fibrosis. Rat that received AdasSPARC showed thinner and immature collagen fibers. They also showed less TGF-β1 levels. We also observed in an in vitro assay that SPARC knockdown in HSC attenuated profibrogenic response induced by fibrogenic cytokines. Consistent with these results, the use of SPARC-/- mice confirmed a reduction in the level of inflammation and fibrosis after treatment with TAA. In this context, microarrays results demonstrated that SPARC-/- mice showed over-expression of genes related to DNA repair and detoxification.

All in all, these results suggest that SPARC is a key player in acute and chronic liver diseases. Therefore, we propose SPARC as a potential therapeutic target for patients with liver injury.

THERAPEUTIC AQUAPORIN GENE TRANSFER IN HEPATOCELLULAR CHOLESTASIS

RAÚL MARINELLI
(Instituto de Fisiología Experimental, CONICET; Universidad Nacional de Rosario, Rosario, Argentina)

Aquaporins (AQPs) are a family of membrane channels that facilitate the osmotically-driven transport of water. The first AQP (i.e., AQP1) was identified in 1992 by Dr. Peter Agre, 2003 Nobel Prize in Chemistry. The mammalian AQPs, which number about a dozen, are expressed in many cell types, including the hepatocyte. Bile formation by hepatocytes is an osmotic secretory process. The excretion of bile salts via the canalicular bile salt transporter BSEP/ABCB11 is thought to be a major driving force for the osmotic, AQP-mediated, water movement into the bile canaliculus. Moreover, a defective canalicular AQP expression, as observed in experimental models of hepatocellular cholestasis (e.g., that induced by estrogens or lipopolysaccharides), is considered an important contributing factor in the development of bile secretory dysfunction. Based on this, we designed and performed studies to assess whether the adenovector AdhAQP1, which encodes for human AQP1 (hAQP1), can promote AQP1-mediated canalicular water secretion and thus improving bile secretory failure in hepatocellular cholestasis. AdhAQP1, administered by retrograde bile ductal infusion, induced hepatocyte canalicular hAQP1 expression and a concomitant increased in canalicular osmotic water permeability [1]. Bile flow as well as choleretic efficiency of endogenous bile salts (i.e., volume of bile per micromol of excreted bile salts) were significantly augmented in cholestasis. This indicates that bile flow improves to some extent by hAQP1-facilitated canalicular water transport [1]. An unexpected finding in hAQP1-transduced cholestatic rats was a significant improvement in the biliary bile salt output, which in turn normalized the elevated serum bile salt levels in cholestasis [2]. Canalicularly expressed hAQP1 unaltered BSEP/ABCB11 protein expression but markedly increased its

transport activity inducing its redistribution to cholesterol-rich canalicular microdomains [2]. Our observations suggest that the hepatic adenoviral transfer of hAQP1 gene to cholestatic rats improves bile secretory failure by increasing both biliary output and choleretic efficiency of bile salts. This finding may have potential as novel treatment for certain liver cholestatic diseases [3].

BILIRUBINOMICS 2017

CLAUDIO TIRIBELLI

(Liver Clinical and Research Center, Teaching Hospital, University of Trieste; Italian Liver Foundation, Trieste, Italy)

Since the first documented observation of a jaundiced patient more than 3000 years ago, bilirubin was considered as a waste product of heme with limited biological activity, a part of being a sign of liver disorders. Gaining scientific attention in the 18th century, the interest on the biological effects of bilirubin longer rotated around its toxic and harmful effects to the brain. At concentrations exceeding the binding capacity of plasma albumin, such as in severe neonatal hyperbilirubinemia and in Crigler-Najjar type I syndrome, (free) bilirubin accumulates in brain inducing mild-temporary (acute bilirubin encephalopathy) or severe-permanent damage (kernicterus). Abnormal motor control, movements and muscle tone, auditory disturbance with or without hearing loss, and oculomotor impairments, are the classical sign of bilirubin neurotoxicity. If untreated, kernicterus is still a cause of death in low-income countries. At the molecular level, bilirubin interplays with multiple targets, modulating a plethora of genes, proteins, and signaling pathway, leading to a pro-inflammatory and pro-oxidant status, excitotoxicity, autophagy, ER stress, cell death, interfering with proliferation and maturation, and showing a remarkable topography for specific brain regions and CNS developmental stages. Only more recently, the advantages of having a moderately higher blood level of the pigment (such as in Gilbert subjects) have been proved. Epidemiological evidence demonstrates benefits (in term of lower incidence and improved conditions) in cardiovascular diseases, certain cancers, Crohn disease, diabetes, and autoimmune and neuropsychiatric diseases. All these conditions presenting inflammation and increased oxidative stress. Paradoxically, at low concentration bilirubin protection occurs via an anti-inflammatory and antioxidant action. Bilirubin is the most potent endogenous antioxidant in the cell (more than tocopherol), due to its continuous recovery by the bilirubin-biliverdin redox cycle. Powered thought the simultaneous activity of heme-oxygenase and biliverdin-reductase, the cycle supplies the cell with fresh bilirubin, consumed (oxidized back to biliverdin) by the presence of intracellular ROS. Notably, the most recent studies indicate a low serum bilirubin level as a potential marker of ongoing chronic pro-oxidant diseases, such as atherosclerosis (risk cut-off 10micromol/liter), Alzheimer disease, dementia, multiple sclerosis, and cerebral infection. Of great interest, and supporting a key role of bilirubin as part of the intracellular anti-oxidant mechanisms, is the recent discovery of UnaG, a protein binding and protecting bilirubin toward oxidation, as an attempt to preserve and store this antioxidant molecule. Notably biliverdin reductase, heme oxygenase, their products (bilirubin, biliverdin, Fe and Co), as well the precursors alanine, behave as signaling molecules not only on the enzymes involved in bilirubin metabolism but also on important cellular controller such as kinases (e.g.. PI3K: phosphatidylinositol-4,5-bisphosphate 3- kinase, IRK: insulin receptor tyrosine kinase, MAPK: mitogen-activated protein kinases) and transcription factors (e.g.: AhR: aryl hydrocarbon receptor, PPAR: peroxisome proliferator-activated receptors, Nrf2: Nuclear factor erythroid-derived 2-like 2). In conclusion, a century of research has multiplied the mechanisms of actions and the biological functions of bilirubin, multiplying the pieces of an intriguing puzzle, resumed by the name “bilirubinomics

LIVER VASCULAR PHYSIOLOGY AND ITS CLINICAL APPLICATION

GABRIEL GONDOLESI

(Instituto de Medicina Traslacional, Trasplante y Bioingeniería, CONICET, Universidad Favaloro, Buenos Aires, Argentina)

The hepatic physiology and circulation have unique and differential characterististics compared to any other organ in the human body.

Some of the unique features include: the dual vascular supply; a mechanism of intrinsic regulation of the hepatic artery; a portal blood flow supplying 2/3 of liver blood flow, which is not controlled directly by the liver; and the fact of receiving 20% of the cardiac output. At histological level, it has a unidirectional blood flow with an extremely distensible capacitance and venous resistance that regulates parenchymal cell metabolic specialization.

The development of chronic liver disease causes a total body circulatory adaptation, opening anatomical and non-anatomical porto-cava shunts, in order to adequate

systemic flow to the increase intrahepatic vascular resistance.
The need to reduce the consequences of this pathophysiological changes, translated into the evolution of therapies from surgical to percutaneous endovascular porto-systemic shunts. The understanding, and the development of the current knowledge on the close relationship between liver flow and hepatic regeneration, favored recent developments in liver surgery; allowing to plan liver resections, expanding not only the indications but also increasing the possibility of applying surgery with curative intent. The applications of those advances in the transplant field allowed to evolve from using whole cadaveric liver transplant to segmental living or cadaveric liver donation, increasing transplant applicability in all ages.
The current available surgical developments that apply to the liver had become one of the best examples of the use of translational physiology and medicine over the last century and become the aim of this presentation.

ALLOSTERIC RECEPTOR-RECEPTOR INTERACTIONS IN HOMO-AND HETERORECEPTOR COMPLEXES GIVE A NEW DIMENSION TO MOLECULAR NEUROSCIENCE AND UNDERSTANDING LEARNING AND MEMORY AND BRAIN DISEASE

KJELL FUXE
(Department of Neuroscience, Karolinska Institutet, Solna, Sweden)

concept of allosteric receptor–receptor interactions in G protein-coupled receptor (GPCR) homo- and heteroreceptor complexes of the central nervous system (CNS) gave a new biological principle to understanding brain integration and neuropsychopharmacology. Allosteric receptor–receptor interactions made possible through receptor oligomerization lead to novel receptor dynamics during which the receptor protomers change their recognition, pharmacology, signaling and trafficking and novel allosteric binding sites can develop. GPCR heteroreceptor complexes can also involve ion channel receptors, receptor tyrosine kinases (RTKs), sets of G protein interacting proteins, ion channels and/or transmitter transporters. There is a need to improve our understanding of the molecular organization of the receptor oligomers, their allosteric communication and the features of the receptor interface. It appears clear that synaptic transmission and volume transmission (extracellular fluid and CSF) in the brain can become integrated in heteroreceptor complexes in the synaptic and perisynaptic membranes built up of ion channel receptors , GPCRs and receptor tyrosine kinases. It enables modulation of synaptic strength and synaptic plasticity in a dynamic way and receptor plasticity is accomplished. Integration of the molecular receptor circuits in the postsynaptic and perisynaptic membranes, respectively can take place through integration of their intracellular molecular signaling pathways in the dendritic spines.
Based on this concept, we proposed that the molecular basis of learning and memory was based on the reorganization of the homo- and heteroreceptor complexes in the postsynaptic membrane of synapses associated with changes also in the presynaptic receptor complexes to facilitate the pattern of transmitter release to be learned. Long-term memory may be created by the transformation of parts of the heteroreceptor complexes into unique transcription factors which can lead to the formation of specific adapter proteins which can consolidate the homo-and heteroreceptor complexes into long-lived complexes with conserved allosteric receptor-receptor interactions. Thus, the homo-heteroreceptor complexes are regarded as highly dynamic assemblies formed or disrupted by integrated synaptic and volume transmission signals. These events are regarded as necessary for learning, and can become transformed into a consolidated rigid state with conserved allosteric communication representing molecular engrams resulting in a major long term modulation of the neuronal networks. This molecular plasticity change, whether transient or long term, can then alter the patterns of outflow in the brain circuits and induce transient and long-term changes in behaviors and cognitive functions. It is now clear through the demonstration of the GPCR heterodimer network (GPCR-HetNet) that the allosteric receptor-receptor interactions dramatically increases GPCR protomer diversity and biased recognition and signaling leading to enhanced specificity in signaling.
Dysfunction or disruption of the heteroreceptor complexes can lead to brain disease. Understanding the D2R heteroreceptor complexes and their dysfunction in schizophrenia can lead to new strategies for its treatment and for avoiding side-effects of antipsychotics known to mainly act as D2R antagonists. This includes a way to optimize combined treatment or single use of heterobivalent drugs targeting distinct D2R heteroreceptor complexes in schizophrenia. This is inspired by current findings on the existence of various types of D2R heteroreceptor complexes in nuc accumbens core and shell.
It was also proposed that novel antiparkinson drugs for the future may be heterobivalent drugs e.g. built up of an A2AR antagonist pharmacophor linked to a D2R agonist pharmacophor specifically targeting the A2AR-D2R het-

erodimer. Other exciting novel targets for antiparkinson drugs are A2AR-D2R-mGluR5 Hets , where A2AR and mGluR5 synergize to put a brake on D2R Gi/o mediated signaling. Emerging new concepts in Parkinson's disease are that dysfunction of the allosteric receptor-receptor interactions and dysbalance of multiple Hets codistributed in the same neuron and synapses of the direct and indirect pathways of the basal ganglia contributes to disease progression and levodopa- induced dyskinesias. Furthermore,the D1 and D2 heteroreceptor complexes in the reward and anti-reward GABA pathways from the nuc accumbens have become exciting new targets for treatment of substance use disorder.The changes found in these receptor complexes in cocaine self-administration opens up a new understanding what goes wrong in cocaine addiction.

HARNESSING THE PLASTICITY OF G PROTEIN-COUPLED RECEPTORS THROUGH ALLOSTERIC REGULATION BY G PROTEINS, SMALL MOLECULES AND CATIONS

ROGER K. SUNAHARA

(Department of Pharmacology, University of California at San Diego, San Diego, California, USA)

G protein-coupled receptors (GPCR) are conduits that sense and communicate extracellular stimuli and transduce their signals across the plasma membrane into intracellular compartments. GPCRs can detect environmental stimuli such as light, odors and tastes, and serve as receptors for hormones, chemokines and even proteases, and modulate downstream effectors that synthesize or regulate second messengers such as cAMP, inositol phosphates and cations. Communication between the receptors and effectors is mediated through the heterotrimeric family of G proteins. Advances in the structural biology of GPCRs have helped unravel the complexities of ligand binding and G protein activation. Analysis of the structural data, along with support from pharmacological and biochemical studies, have aided in developing models of how hormone binding leads to G protein activation. Here we describe the allosteric relationship between G protein binding and the hormone binding site, where G proteins potently enhance the affinity of hormone agonists. Through understanding the structural basis of this cooperativity we further provide a rational foundation for the efficacy of allosteric modulators, as well as a novel allosteric modulator binding site on the beta$_2$ adrenergic receptor. An understanding of the mechanisms underlying this allostery was also useful to describe a major role of additional co-factors, such as cations, as allosteric modulators in the stabilization of inactive and active states of GPCRs. These data highlight the complex nature of the cooperativity existing between small molecules and G proteins in stabilizing specific GPCR conformations and illustrate their impact on drug discovery and development.

MOLECULAR AND STRUCTURAL DETERMINANTS OF GPCR FUNCTIONAL SELECTIVITY AND SIGNAL PROPAGATION

MICHEL BOUVIER

(Department of Biochemistry and Molecular Medicine, Faculty of Medicine and Institute for Research in Immunology and Cancer, Université de Montréal, Montréal, Canada)

It is now clear that G protein-coupled receptors (GPCRs) are not uni-dimensional switches that turn 'on' or 'off' a single signaling pathway. Instead, each receptor can engage multiple signaling partners to form dynamic complexes that can engage various downstream effector systems that may or may not involve G protein activation. Individual ligands can have differential efficacies toward specific subsets of the signaling effector repertoire engaged by a given receptor. This phenomenon, known as ligand-biased signaling or functional selectivity, opens new opportunities for the development of new drugs with increased selectivity profiles and less undesirable effects. Yet, this pluridimensional nature of signaling efficacy presents a challenge to establish the complete signaling profile of drugs. To better assess multiple signaling outcomes and unravel the structural basis of GPCR functional selectivity, we developed a diversity of biosensors based on bioluminescence resonance energy transfer (BRET) that allow real-time monitoring of multiple GPCR effectors and downstream signaling events. We generated more than 40 BRET-based sensors that monitor a large diversity of signaling pathways with unprecedented spatio-temporal resolution in living cells. In addition we developed label-free approaches that permit assessing the integrated cellular responses and dissecting the relative contribution of the contributing signaling pathways. Their combined use with BRET sensors revealed unexpected signaling texture and provide a new tool-set to monitor signal transduction from the membrane to intracellular organelles including endosomes, opening new avenues for the screening and profiling of drug candidates with favorable functional selectivity. At the molecular level, molecular modeling and site-directed mutagenesis revealed that specific domains of receptors play crucial roles for the activation of selective pathways, providing insights into the rational design of biased ligands with desired signaling properties.

DIFFERENT CHEMICAL BIOLOGY APPROACHES TOWARDS MODULATION OF GPCR SIGNALING

ROB LEURS
(Vrije Universiteit, Amsterdam, The Netherlands)

GPCRs are one of the most effective signaling devices, that regulate a plethora of physiological responses via the effective coupling to a diverse set of signaling pathways. The histamine H_3 receptor (H_3R) is a GPCR that regulates neurotransmitter release and is consequently involved in various CNS functions via the coupling of a set of GPCR isoforms to various signal transduction pathways. To elucidate the role of these isoforms and their various signaling pathways, our lab has been developing new tools to distinguish H_3R isoforms and signaling pathways in order to selectively affect G-protein and/or non-G-protein signaling pathways.

Photoswitchable ligands are starting to emerge in the field of GPCRs as another set of pharmacological tools to control receptor activityat will. It has been shown that photoisomerization can change ligand affinity for the receptor as well as its efficacy. Photoswitchable ligands often contain an azobenzene moiety that is able to reversibly photoisomerize from the *trans* to *cis* isomer upon illumination with specific wavelengths. neurological disorders. In this presentations, a novel series of photoswitchable antagonists for the histamine H_3 receptor will be presented. Within this series binding affinity shifts of over 10-fold were found upon treatment with light. In this presentation, a highly complementary bidirectional photo-antagonist and agonist toolbox is presented, which allows dynamic regulation of histamine induced H_3R activation with high temporal resolution. These photopharmacological tools can be of aid in spatio-temporal studies to study H_3R signalling.

MACROPHAGE IMMUNOMETABOLISM IN METABOLIC AND INFLAMMATORY DISEASES

PEDRO M. MENDES DE MORAES VIEIRA
(Istituto de Biologia, Universidade Estadual de Campinas, Campinas, Brazil)

The interface between immunology and metabolism leaded to the understanding of many metabolic disorders in which the immune system function is essential, such as in diabetes, atherosclerosis and autoimmune diseases. A key finding that emerged from this context is that the metabolism integrates all other biological systems. The adipokines are one example of molecules that integrates the metabolism with the immune systems. The adipokines include leptin, adiponectin, retinol binding protein 4 (RBP4), among others. RBP4, a retinol transporter, is elevated in insulin resistance and contributes to increased diabetes risk. RBP4 has an essential role in inflammation-induced insulin resistance. Insulin resistance is a major cause of diabetes and is highly associated with adipose tissue (AT) inflammation in obesity. RBP4 elevation causes AT inflammation by activating innate immunity that elicits an adaptive immune response. RBP4 overexpression leads to insulin resistance and increased AT macrophage and CD4 T cell infiltration. RBP4 overexpression changes AT $CD206^+$ macrophage phenotype, enhancing the expression proinflammatory markers and activation of CD4 T cells while maintaining alternatively activated macrophage markers. These effects result from direct activation of AT antigen-presenting cells (APCs) by RBP4 through a JNK-dependent pathway. Blockade of antigen presentation or reduction on RBP4 levels improves insulin resistance and adipose tissue inflammation. RBP4 promotes a metabolic switch favoring glycolysis in adipose tissue M2 macrophages. Glycolysis inhibition block RBP4-induced macrophage activation. RBP4 effects on the metabolic switch of macrophages rely on the Hypoxia inducible factor 1 alpha (HIF-1α). HIF-1α expression is elevated in adipose tissue M1 and M2 macrophages from RBP4 overexpressing mice, which display a differentiated metabolomic phenotype. Thus, RBP4 has a central role in macrophage metabolic fitness during inflammation-induced insulin resistance.

MTOR SIGNALLING IN MACROPHAGES

THOMAS WEICHHART
(Center of Pathobiochemistry and Genetics, Institute of Medical Genetics, Medical University of Vienna, Vienna, Austria)

The interface between immunology and metabolism leaded to the understanding of many metabolic disorders in which the immune system function is essential, such as in diabetes, atherosclerosis and autoimmune diseases. IMMUNE REGULATION AT BARRIER SURFACES

DAVID ARTIS

(Weill Cornell Medical College, Cornell University, New York, USA)

Employing models of microbial colonization, pathogen infection, chronic inflammation and tissue repair, research in the Artis lab is examining how mammalian host genetics and signals derived from the environment and commensal microbial communities influence innate and adaptive immune cell responses at the body's barrier surfaces. We are employing gnotobiotic mice to examine the influence of defined commensal microbial communities on intestinal and peripheral immune cell development, function and influence on tissue homeostasis. Our recent findings indicate that commensal microbes have a significant regulatory influence on lymphocyte, innate lymphoid cell and granulocyte function associated with susceptibility to multiple infectious, inflammatory and metabolic disease processes. We have also developed a number of translational immunology projects, including analysis of tissue samples from patients with atopic dermatitis, food allergy, obesity and IBD. It is hoped that the results of these basic and translational studies will advance understanding of the pathophysiology of multiple chronic inflammatory diseases, including asthma, allergy, inflammatory bowel disease and obesity, and provide a framework to test new therapeutic pathways to prevent and treat these diseases.

GENOMIC INSTABILITY & DNA REPAIR: LESSONS FROM CANCER, NEURODEGENERATION AND AGING
THE NASCENT DNA: A SIGNALING TOOL BELT THAT INTEGRATES MULTIPLE PATHWAYS IN CELLS

VANESA GOTTIFREDI
(Fundación Instituto Leloir, CONICET, Buenos Aires, Argentina)

The duplication of DNA is an essential process required to produce viable daughter cells. To achieve such an endeavor, the replication machinery needs to readily copy almost two meters of template DNA in approximately 5 hours (the length of an S phase). Such difficult task is further challenged by the frequent chemical modifications of the template DNA. Hence, a signaling network known as DNA damage response (DDR) is activated to guarantee replication adaptation to damaged DNA. While the DDR preserves healthy cells from unnecessary death, it also aids tumor cells when escaping from the harmful effects of DNA damaging agents. Hence, understanding the DDR may serve to identify important targets in cancer therapy.

Our current understanding of the DDR indicates that it gets activated when the replicative DNA polymerases are blocked by DNA lesions. A first DDR option is to tolerate the DNA lesion, meaning that the nascent DNA is synthesized by alternative methods, including the synthesis of DNA by specialized DNA polymerases that can use the damaged DNA as replication templates. A second DDR option is activated when the DNA lesion is not tolerated and the DNA replication is halted. In this case, the stalling of the replisome generates checkpoint signals that spread throughout the nucleoplasm, preventing further initiation of DNA replication events elsewhere. Such reduction in the DNA replication speed creates a temporal window to repair DNA lesions, diminishing the global frequency of encounter of DNA lesions by active replication forks. If option 1 and 2 fail, the replication fork breaks, requiring homologous recombination repair for its reconstitution. Such a linear pathway represents an oversimplification of the sophisticated way in which DDR works. In fact, I will present data demonstrating unanticipated levels of complexity in the interaction between DDR pathways. Such findings may facilitate the identification of key proteins of this network that should be targeted to dismantle the DDR of tumor cells.

REGULATION OF BASE EXCISION REPAIR IN THE AGING BRAIN

RICARDO GREDILLA
(Departamento de Fisiología, Facultad de Medicina, Universidad Complutense de Madrid, Madrid, Spain)

Aging is characterized by reduction in physiological functions. The detrimental effects of aging are best observed in postmitotic tissues, where cells that are irreversibly damaged or lost cannot be replaced. Among such tissues the brain is most important one due to its main role in homeostasis of the organism. Brain aging is characterized by increased susceptibility to neuronal loss and functional decline leading to cognitive impairment. Mitochondrial DNA (mtDNA) mutations are thought to play an important role in these processes. Increased levels of oxidative DNA damage and accumulation of mtDNA mutations have been linked to mitochondrial dysfunction, thus contributing to the aging process. Moreover, increased mtDNA instability has been also associated with the pathogenesis of neurodegenerative diseases such as Alzheimer's disease.

In order to maintain genomic stability, different DNA repair pathways have evolved. Base excision repair (BER) is the primary DNA repair pathway for small DNA modifications caused by oxidation, alkylation or deamination, both in nuclei and mitochondria. During the last years we have investigated the potential role of DNA repair mechanisms in the aging process and age-related neurodegenerative disorders. Brain regions involved in cognition processes, such as cortex and hippocampus, as well as specific subcellular fractions like synaptosomes have been analyzed during normal aging and different animal models of neurodegeneration. Our investigations suggest that a decline in the BER capacity is an important factor in the brain aging process and in the onset and course of age- related neurodegenerative diseases. A better understanding of the underlying mechanisms of the aging process would lead to significant advances in the search of strategies to improve brain aging as well as therapeutic treatments of neurodegenerative diseases.

OVARIAN HORMONE DEPRIVATION AND HORMONE REPLACEMENT THERAPY EFFECTS ON MITOCHONDRIAL DNA REPAIR PROCESSES IN THE BRAIN

SANDRA ZÁRATE
(Instituto de Investigaciones Biomédicas, CONICET; Facultad de Medicina,

Universidad de Buenos Aires, Buenos Aires, Argentina)

Sex steroids exert pleiotropic effects in the brain, preserving neural function and promoting neuronal survival. Not surprisingly, loss of ovarian hormones during natural or induced reproductive senescence in the female is characterized by synaptic and cognitive impairments and increased risk of neurodegeneration, processes that are now recognized to be highly associated with mitochondrial dysfunction. Multiple lines of evidence point for brain mitochondria as targets of steroid hormone action. In fact, a link between sex-dependent susceptibility and decline in brain mitochondrial function has been identified in normal aging as well as in neurodegenerative diseases both in preclinical animal studies as well as in women after natural or surgical menopause. Mitochondria are key players in cellular bioenergetics and survival, they are the main source of ATP production and also the primary sites for cellular reactive oxygen species (ROS) generation. These organelles are unique in terms of having their own genome, which is more prone to oxidative damage than the nuclear genome in part due to its close proximity to the source of ROS production. Accumulative damage in mitochondrial DNA (mtDNA) over time, if not properly repaired, leads to mitochondrial dysfunction and disease. As an organ with a high demand of energy and low antioxidant capacity, the brain is particularly vulnerable to mitochondria dysfunction and oxidative stress. Base excision repair (BER) is the major DNA repair pathway in mitochondria, thereby constituting an important mechanism to avoid accumulation of mtDNA mutations. Still, little is known about how hormonal status affects mtDNA repair mechanisms in the brain. Moreover, the heterogeneity of organization, function, and biochemical mechanisms in the brain implies that some regions may be particularly vulnerable to ovarian hormone loss and accumulation of mtDNA damage. In this context, we are studying the effects of long-term ovarian hormone deprivation and early hormone-replacement treatments on BER pathway in mitochondria from rat cortex and hippocampus, areas primarily affected in aging and neurodegenerative diseases and highly responsive to ovarian hormones. Our data suggest that hormonal status regulate BER pathway in a region-specific manner and poises the hippocampus as a highly vulnerable area to ovarian hormone loss regarding impaired BER capacity. Considering the importance of preserving mtDNA integrity for normal cell function, this study provides insights into the role of early hormone replacement therapy in mtDNA repair capacity and could help find new therapeutic targets to promote a healthier lifespan for women after natural or induced menopause.

MAJOR ROLES OF PYRIMIDINE DIMERS, NUCLEOTIDE EXCISION REPAIR AND ATR IN THE ALTERNATIVE SPLICING RESPONSE TO UV IRRADIATION

MANUEL MUÑOZ

(Instituto de Fisiología, Biología Molecular y Neurociencias, CONICET; Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Buenos Aires, Argentina)

We have previously found that UV irradiation promotes RNA polymerase II (RNAPII) hyperphosphorylation and subsequent changes in alternative splicing (AS). We show now that UV-induced DNA damage is not only necessary but sufficient to trigger the AS response and that photolyase-mediated removal of the most abundant class of pyrimidine dimers (PDs) abrogates the global response to UV. We demonstrate that, in keratinocytes, RNAPII is the target, but not a sensor, of the signaling cascade initiated by PDs. The UV effect is enhanced by inhibition of gap-filling DNA synthesis, the last step in the nucleotide excision repair pathway (NER), and reduced by the absence of XPE, the main NER sensor of PDs. The mechanism involves activation of the protein kinase ATR that mediates the UV-induced RNAPII hyperphosphorylation. Our results define the sequence UV-PDs-NER-ATR-RNAPII-AS as a pathway linking DNA damage repair to the control of both RNAPII phosphorylation and AS regulation.

ADIPOSE TISSUE INFLAMMATION AND METABOLIC SYNDROME: PROTECTIVE ROLE OF BIOACTIVE GRAPE-DERIVED COMPOUNDS

MARCELA VÁZQUEZ PRIETO

(Instituto de Medicina y Biología Experimental de Cuyo, CONICET, Universidad Nacional de Cuyo, Mendoza, Argentina)

Metabolic syndrome (MetS) is a cluster of symptoms that include increased waist circumference (abdominal adiposity), plasma triglycerides, and fasting glycemia; reduced high-density lipoprotein (HDL) cholesterol; and

hypertension. The increasing incidence of MetS, which occur in parallel with the increase of obesity, currently affects 34% of the world population and is associated with the development of insulin resistance, type 2 diabetes (T2D), and cardiovascular disease, constituting a major public health concern worldwide. Hypertrophy of adipocytes, particularly from visceral adipose tissue, causes an increase production and secretion of pro-inflammatory adipocytokines such as tumor necrosis factor alpha (TNFα), monocyte chemoattractant protein 1 (MCP-1), resistin, interleukin 6, among others. Although the mechanisms are not completely understood, these pro-inflammatory cytokines drive the recruitment and activation of macrophages and other immune cells that completes a cycle of inflammation and impaired metabolic function, contributing to adipose insulin resistance. Diet can play a major role in the prevention of MetS and its associated pathologies. Epidemiological studies show that consumption of fruits and vegetables in humans decreases the risk of MetS. Grape pomace (GP) is a waste product, containing predominantly a left-over of skins and seeds, generated in the winemaking process which contains relatively high amounts of bioactive compounds like polyphenols and dietary fiber. Polyphenols are naturally occurring plant compounds that have a multiplicity of biological effects. The most abundant polyphenols identified in malbec GP are flavanols such as (-)-epicatechin, flavonols, anthocyanins, hydroxybenzoic and hydroxycinnamic acids, and stilbenes. The protective effect of certain polyphenols on adipose tissue dysfunction are attributed to the capacity to modulate cell signaling cascades involved in inflammation and insulin resistance, interaction with enzymes, transcription factors, and receptors among others. Overall, bioactive grapederived compounds constitute an interesting alternative to modulate/mitigate adipose tissue inflammation associated with MetS and obesity.

EFFECTS OF ANTIOXIDANTS ADMINISTRATION IN EXPERIMENTAL METABOLIC SYNDROME

CARLOS REYES TOSO

(Facultad de Medicina, Universidad de Buenos Aires, Buenos Aires, Argentina)

Metabolic syndrome (MS) is a cluster of abnormalities, including among others, abdominal obesity, hypertension, glucose intolerance or diabetes and dyslipidemia (hypertriglyceridemia and/or low HDL cholesterol). The US National Cholesterol Education Program–Adult Treatment Panel III (ATPIII-2005) and the Joint Interim Statement -2009- (International Diabetes Federation; American Heart Association; National Heart, Lung, and Blood Institute; World Heart Federation; International Atherosclerosis Society; and the International Association for the Study of Obesity) defines MS as the combined occurrence of at least three of the above mentioned five risk factors. This syndrome increase the risk for cardiovascular disease and type 2 diabetes, and recently it has been associated with other pathological entities such as Nonalcoholic Fatty Liver Disease (NAFLD), renal dysfunction, cancer (liver, pancreas, bladder and breast) and dementia. It is estimated that approximately 20 % of world's adult population has MS.

Visceral obesity and insulin resistance (IR) are currently considered the primary underlying factors in the development of this syndrome. It has been reported that proinflammatory state of visceral obesity induces IR, leading to clinical and biochemical manifestations of MS. Furthermore, oxidative stress is associated with IR, visceral fat accumulation, and MS. In the last decade, excessive oxidative stress has been proposed as a common pathological mechanism for the development of systemic lesions.

The MS induced in rats by the administration of high-fructose and high-fat diets mimics the syndrome described in humans, but in contrast to patients rats' body weight is not significantly increased (although visceral adipose tissue mass is expanded).

A major contributor to the development of IR is an overabundance of circulating free fatty acids (FFA). These FFA induce IR in muscle by inhibiting insulin-mediated glucose uptake. Increased levels of circulating glucose augment glycolysis and production of diacylglycerol (DAG). DAG stimulates the activity of protein-kinase C (PKC) and so interferes with intracellular insulin signaling. The metabolic alterations above mentioned increase oxidative stress through an increase in reactive oxygen species (ROS), specially mitochondrial and extra-mitochondrial ($^{\cdot}0_2^-$). PKC also induce NADP(H)-oxidase with the production of more ($^{\cdot}0_2^-$). Furthermore the activation of the polyol pathway results in a decrease of intracellular levels of NADPH which leads to reduced synthesis of antioxidant substances. ROS produced, as mentioned earlier, can cause DNA and mitochondrial damage, lipid peroxidation and therefore disrupt the membrane lipid bilayer arrangement that may inactivate membrane-bound receptors and enzymes and lead to cell death.

Several studies of chronic administration of antioxidants substances to fructose-fat fed rats have shown a reduction in blood pressure, triglycerides, total cholesterol and FFA and increased plasma HDL-cholesterol concentration. Even though the exact mechanism that triggers these effects has not been fully elucidated, the results mentioned above suggest that upregulated oxidative stress promotes the development of MS. Even though a great number of clinical trials show that most antioxidants exhibit a wide range of effects in protecting against ROS, results are still controversial. At this point no strong recommendation can be made for the use of these compounds in clinical practice.

PRO-ATHEROGENIC ALTERATIONS IN METABOLIC SYNDROME

FERNANDO BRITES
(Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, Buenos Aires, Argentina)

The metabolic syndrome is defined as the concurrence of mutually associated cardiovascular risk factors including abdominal obesity, impaired glucose tolerance, hypertriglyceridemia, decreased high density lipoprotein (HDL)-cholesterol, and/or hypertension. In association with these factors, many investigators have described the activation of the sympathetic nervous system, renin-angiotensin system, and increased levels of proinflammatory adipokines and cytokines. The original conceptualization of this syndrome focused on a central role of insulin resistance, and this is clearly a concurrent and associated feature. More recently, the focus has been on the metabolic syndrome as an epidemiologic tool related to cardiovascular disease risk, and therefore traditional cardiovascular disease risk factors have been adopted as the defining features. Although the precise definition of what clinically constitutes the metabolic syndrome has generated considerable debate, it is well accepted that these comorbidities represent a pathological state that substantially augments risk for the development of type 2 diabetes mellitus and atherosclerotic cardiovascular disease. In previous studies, we have described diverse proatherogenic alterations associated with metabolic syndrome which include: a) hypoadiponectinemia, b) high soluble vascular cell adhesion molecule (VCAM)-1 and leukocyte adhesion molecule expression (monocyte CD54 and lymphocyte CD49d), c) an atherogenic lipid and lipoprotein profile, and d) altered HDL chemical composition and cardioprotective functions, accompanied by higher cholesteryl ester-triglyceride interchange carried out by cholesteryl ester transfer protein (CETP). In this pathological condition, CETP seems to be highly determinant of the metabolic syndrome-associated dyslipidemia. Of clinical relevance, CETP activity may be acceptably predicted by non-HDL-cholesterol and HOMA index. Moreover, CETP would also have a remodelling action on very low density lipoprotein (VLDL) in circulation, favouring, together with hepatic lipase, the formation of highly atherogenic small and dense low density lipoprotein (LDL) particles in patients with metabolic syndrome-associated hepatic steatosis, who, despite the presence of intrahepatic fat, also secreted higher number of VLDL particles. Hepatic steatosis was further associated with larger and triglyceride over-enriched circulating VLDLs, of greater atherogenicity. However, when hepatic steatosis progressed to severe fibrosis, circulating VLDL features apparently improved, probably due to early alterations in hepatic synthetic function. Furthermore, simple hepatic steatosis would play an important role increasing cardiovascular risk, independently of insulin resistance. Thus, metabolic syndrome was shown to be closely related to alterations of the whole lipoprotein spectrum as well as to many other proatherogenic metabolic disturbances.

METABOLIC SYNDROME AND MALE HYPOANDROGENISM

PABLO COSTANZO
(Servicio de Endocrinología, Metabolismo y Medicina Nuclear, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina)

The prevalence of metabolic syndrome is significantly increasing over the years in direct relation to negative changes in eating habits and lifestyle. Several studies have shown that men with metabolic syndrome have significantly lower testosterone levels and a higher prevalence of hypogonadism. In recent years, great advances have been made in understanding the pathophysiological mechanisms underlying this association.

Patients with metabolic syndrome are considered to have lower testosterone levels due to multiple mechanisms secondary to obesity and insulin resistance; however, there is increasing evidence of an effect of hyperglycemia per se on the gonadal axis.

In obesity and in hyperinsulinemia secondary to insulin resistance, often present in patients with metabolic syndrome, there is a decrease in total testosterone related to lower sex hormone binding globulin levels resulting from decreased hepatic synthesis of this protein. However, in obesity, as well as in hyperinsulinemia, there is also a decrease in free and bioavailable testosterone levels, which implies a real decline in testosterone production.

In hypogonadal patients with metabolic syndrome or type 2 diabetes, gonadotropin levels are usually normal or low, which supports the diagnosis of hypo- or nor-

mogonadotrophic hypogonadism in most of these men. This reinforces the possibility of a failure at central level, which may be due to a hypothalamic defect and/or to an absence of pituitary response to GnRH.

Other proposed mechanisms is the negative-feedback inhibition of the gonadal axis at the hypothalamic-pituitary level due to higher estradiol concentrations secondary to a greater conversion of androgens into estrogens by the increased aromatase enzyme activity in adipose tissue.

Cell culture studies show that insulin stimulates the gonadal axis activity at all three levels: hypothalamic, pituitary and testicular. Patient with metabolic syndrome have hyperinsulinemia with hypoandrogenism. Anyway, this apparent paradox may be explained by the decreased insulin sensitivity observed in insulin-resistant states.

Leptin is also involved in the regulation of the activity of the gonadal axis. It has been proposed that kisspeptin neurons would play an important role in the nutritional/metabolic/reproductive integration. Kisspeptins are peptide ligands of the receptor GPR54, with stimulating effects on GnRH neurons. It has been demonstrated that kisspeptin neurons have leptin receptors and experimental data would allow us to conceive kisspeptins as mediators of leptin action on GnRH and as being part of the pathophysiology of hypogonadism in obesity. Hypothalamic NPY (a potent inhibitos of gonadal axis) neurons also express leptin functional receptor and might exert at this level an effect similar to that of insulin inhibiting NPY expression. Thus, resistance to leptin in obese subjects lower central effects of leptin with lower GnRH secretion and, in addition, hyperleptinemia secondary to leptin resistance inhibits testosterone secretion at the testicular level.

Inflammatory cytokines produced in adipose tissue may also contribute to the lower synthesis of testosterone at testicular level. By last, recent studies demonstrate the direct effect of hyperglycemia on the pituitary hypothalamus axis, with inhibition of hypothalamic activity.

USE OF A PERSONALIZED MEDICINE STRATEGY TO IMPROVE THE SAFETY AND EFFECTIVENESS OF ISONIAZIDE TREATMENT

GUILLERMO ALBERTO KELLER

Centro de Vigilancia y Seguridad de Medicamentos, Facultad de Medicina, Universidad de Buenos Aires, Buenos Aires, Argentina.

Isoniazid is metabolized by genetically polymorphic NAT2. Different alleles are associated altered acetylation capacity and risk for drug decreased efficacy or toxicity. NAT2 polymorphism is also involved in the metabolism of many chemical compounds with clinical consequences. Methods: An oral isoniazid dose was prescribed to subjects, and three hours later blood was extracted for NAT2 genotyping (PCR-RFLP) and phenotyping (quantification of isoniazid and metabolite concentrations). Results: A chromatographic technique was validated for the simultaneous determination of isoniazid and acetyl-isoniazid. A total of 188 subjects (1 month to-44 years old), with no history of allergy or adverse reactions to isoniazid were analyzed. They received a weight-adjusted dose of 4.56 ± 0.89 (3.05-5.99) mg / kg. The present alleles were determined as: *4 (35.00%), *5 (41.00%), *6 (21.00%) and *7 (2.50%). Concentrations of isoniazid and its main metabolite were 3.16 ± 1.21 (1.51-5.83) µg / mL and 6.57 ± 4.82 (0.10 - 18.24) µg / mL, with an acetyl-isoniazid / isoniazid (MR) molar metabolic coefficient of 2.56 ± 2.23 (0.02-9.04). Antimodes of the trimodal distribution of MR (Rapid> 5.4, Intermediate 1.2 to 5.4 and Slow <1.2) were calculated for genotype/phenotype concordance analysis. A maturation process in pediatric subject was identified, reaching full metabolic capacity at 4 years. Discussion: The allelic distribution of the local population shows its own frequency and slightly different from that reported in other populations and studies. Both genotyping and phenotyping allow the differentiation of metabolic profiles that could be linked to the development of problems of lack of efficacy and/or toxicity and can be used in the provision of therapeutic individualization services. Genotype accurately predicts metabolic activity. Conclusions: pharmacogenetic NAT2 study is a useful tool for the differentiation of metabolic behaviors and eventual therapeutic individualization.

AN INCREASE IN NMDAR-GLUN2A EXPRESSION AS A LONG TERM MEMORY CONSOLIDATION MARKER

MARÍA VERONICA BAEZ (1), MAGALI CERCATO (1), ANNA DE TOMAS LIORIO (1), TOMAS GONZALEZ GARELLO (1), MA. FLORENCIA ACUTAIN (1), EDGAR KORNISIUK (1), NICOLAS LAVAISE (1), CLAUDIO CUELLO (2), DIANA JERUSALINSKY (1)

(1)Instituto de Biología Celular y Neurociencia "Profesor Eduardo De Robertis" (IBCN), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Universidad de Buenos Aires (UBA), Buenos Aires, Argentina. (2) McGill University, Montreal, Quebec, Canadá.

NMDA receptors (NMDAR) play a critical role in synaptic plasticity, memory encoding and storage. These receptors are composed by two obligatory GluN1 subunits and two regulatory subunits: GluN2 (A-D) or GluN3 (A-B), being GluN2A and GluN2B the major regulatory subunits in central areas related to cognitive functions. It was already shown that there is an increase of GluN1 and GluN2A 70' after 5' exploration leading to habituation to a new environment (an open field: OF), in the hippocampus of 1, 2 and 3 month old Wistar rats. As this NMDAR subunits increase could be related to memory tracing; hence, we investigated if those changes would take place following other learning paradigms like object recognition (OR) or inhibitory avoidance (IA) tasks. In this work we show that 70' after OR training there is a significant increase in hippocampal GluN1 and GluN2A NMDAR subunits. As OR task depends on prefrontal cortex (CPF) we investigated if there is a change in CPF NMDAR subunits, however we found that GluN1, GluN2A and GluN2B subunits remains similar to controls, at least at the analyzed times.

Then we decided to investigate if similar changes occurs after IA training. As IA memory is related to amygdala, we decided to analyze also this structure. Western blot analysis shown that there is an increase in GluN1 and GluN2A subunits 70' after IA training in hippocampal protein extracts and also in amygdala extracts. However, these results does not demonstrate that NMDAR subunits changes is associated with memory consolidation. For this reason, we work with McGill APP rats that are an Alzheimer disease's model. In those rats, where IA LTM is not consolidated, NMDAR subunits did not change after IA training. These results strongly suggest that changes in hippocampal NMDAR subunits could be part of the trace of new spatial memories.

ROLE OF RAC3 COACTIVATOR IN CELLULAR DIFFERENTIATION

MARÍA FERNANDA RUBIO

Instituto de Investigaciones Médicas (IDIM), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Universidad de Buenos Aires (UBA), Buenos Aires, Argentina

Abstract: RAC3 is a member of the p160 family of Steroid Receptor Coactivators and is highly expressed in several human cancers, contributing to cell proliferation and cellular transformation. In this work, we have studied the role of RAC3 during adipogenesis. This is a highly regulated process which involves the cell cycle arrest and changes in the gene expression pattern, which is required for morphological remodeling. We found that RAC3 expression levels are downregulated during specific stimulus induced-adipocyte differentiation. Moreover, a constitutive decrease of RAC3 expression through a shRNA potentiates adipocyte differentiation shortening the time at which the adipocyte markers Perilipin, PPAR- and Oil Red O staining are detected. The RAC3 down regulation favors cell arrest and autophagy. Early and late autophagy inhibitors block adipocyte differentiation of control cells, but inhibit the shRAC3 differentiation partially. Although autophagy is required for adipogenesis, these results suggest that additional signals could be triggered by RAC3 down regulation. We conclude that RAC3 is a key regulator of adipogenesis whose down regulation generates cellular arrest and a permissive environment for autophagy allowing the early adipocyte differentiation.

STUDY OF ISOMERASE PROTEINS AS NEW REGULATORS IN THE ACTIVATION OF TRANSCRIPTION FACTORS RELATED TO STRESS AND INFLAMMATION

ALEJANDRA ERLEJMAN

Instituto de Química Biológica de la Facultad de Ciencias Exactas y Naturales (IQUIBICEN), Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires (UBA), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Buenos Aires, Argentina

Abstract: The study of proteins involved in biological response is important in order to promote the discovery of new regulators in signalling pathways. In certain malignancies, it is known that some pathways are altered, such as Nuclear Factor Kappa B (NF-kB) and Activator Protein 1 (AP-1) in chronic inflammation. In particular, we study new regulators for the activation of transcription factors related to stress and inflammation such as NF-kB and AP-1, with the final goal of provide new molecular target as a promising approach in therapeutic field. FK506-binding proteins (FKBPs) are Hsp90 Co-chaperones with peptidylprolyl-isomerase enzymatic activity, suppressed by the FK506 drug. Previously, FKBP51 and FKBP52 were characterized as steroid receptors modulators. We demonstrated that FKBP51 impairs NF-kB (p65/p50) activity, while FKBP52 enhances it. Furthermore, NF-kB target genes were highly induced by FKBP52, and its isomerase activity was decisive in this regulation. Importantly, both basal phospho-p65 and total p65 protein level were increased by FKBP52. In this context NF-kB activity was favored by a higher FKBP52/FKBP51 ratio. Moreover, in trophoblast cells AP-1 has an important regulatory role. Preeclamptic placentas show alterations on c-fos and FKBP52 expression. Our findings revealed that FKBP52 stimulated AP-1 transcriptional activity and promoted greater c-fos protein level. Interestingly, the overexpressed FKBP52 produced higher level of pERK/ERK for longer time. We propose FKBP52 as new key regulator on AP-1 and NF-B signalling, emphasizing its isomerase activity as essential. Thus, we suggest FKBP52 isomerase activity as an interesting target to prevent AP-1 and NF-kB biological activity.This findings represent a novel contribution in the development of new therapeutic agents for inflammatory diseases. Financial support: UBA, CONICET and PICT 2015-1603

CÉSAR MILSTEIN AWARD

CRYSTAL VIOLET CHEMICAL ANALOGUES INHIBIT THE Trypanosoma cruzi PROLINE TRANSPORTER TcAAAP069 AND EXERT TRYPANOCIDAL EFFECT.

MELISA MARTINEZ SAYÉ, LUCRECIA GAUNA, CHANTAL REIGADA, MARIANA MIRANDA, CLAUDIO A. PEREIRA

Laboratorio de Parasitología Molecular, Instituto de Investigaciones Médicas A. Lanari (IDIM), Facultad de Medicina, Universidad de Buenos Aires, Consejo Nacional de Investigaciones Científicas y Técnicas, Buenos Aires, Argentina.

Trypanosoma cruzi, the etiological agent of Chagas disease, has a metabolism largely based on the consumption of glucose and proline. Proline is also involved in differentiation processes, cellular invasion and resistance to oxidative, metabolic and osmotic stress. We have previously identified the proline permease TcAAAP069 in *T. cruzi* and we showed the importance of this transporter on parasite survival. Crystal violet (CV) was used for several years as a blood additive for prevention of transfusion transmitted Chagas disease. Among the trypanocidal mechanisms proposed for CV, it was reported the protein synthesis inhibition related to inhibition of methionine and proline transport. The aim of this work was to validate CV as a proline transport inhibitor in order to use it as reference in a virtual screening protocol. CV entered at least in part through the proline permease TcAAAP069 and it also inhibited proline transport. Transgenic parasites overexpressing proline transporter (Tc069 parasites) were more sensitive to CV trypanocidal action (12.7μM for control parasites and 0.27μM for Tc069 parasites). The protective effect of proline in oxidative stress situations led to a 3-fold increase resistance for Tc069 parasites when proline was added along with CV. In order to obtain other drugs that might have similar effects to CV, a similarity-based virtual screening was performed, using the CV as query and different drug databases of compounds approved for use in humans. So far, three of the obtained compounds proved to be effective as proline transport inhibitors that also had trypanocidal effect. Taken together, these results show that it is possible to identify potential trypanocidal compounds by virtual screening using CV as a reference. Drug repositioning is a recommended strategy by the World Health Organization to fight neglected diseases, like Chagas disease, since costs and development time are significantly reduced for its application in therapy.

DAMAGE ASSOCIATED MOLECULAR PATTERN HMGB1 EFFECTS IN NEURONAL SYNAPTOGENESIS AND PROPAGATION OF REACTIVE GLIOSIS

GERARDO A. ROSCISZEWSKI, MARÍA VANESA CADENA, JERÓNIMO LUKIN, ANALÍA REINES, ALBERTO JAVIER RAMOS

Instituto de Biología Celular y Neurociencias "Prof. E. De Robertis" (IBCN), Universidad de Buenos Aires (UBA), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Buenos Aires, Argentina.

High-mobility group box-1 (HMGB1) is a DAMP released after focal brain injury that activates local innate immunity cells but also behaves as cytokine acting on the professional immune organs of the periphery. Local brain innate immunity cells are microglia and astrocytes that express pattern recognition receptors such as TLR2-4 and RAGE. We here dissected the HMGB1 effects on astrocytes, microglia and neurons and studied the downstream signaling. Primary astroglial cultures containing different amounts of microglial cells were obtained from postnatal 3-4 days rats or wt/TLR2KO/TLR4KO mice and primary neurons were from E18 rat embryos as described in detail in Rosciszewski et al., Mol.Neurobiol. (2017). In vivo, focal hemorrhagic brain ischemia was induced by cortical devascularization and animals received sulphazalazine (200mg/kg every 12hours) for 3 days. Our results showed that purified primary cortical neurons exposed to 50 or 500 ng/ml HMGB-1, presented a rapid increase in the number of synaptic puncta per neuron without showing significative neuronal loss. However, primary neurons exposed to conditioned medium secreted by 500 ng/ml HMGB1-treated astrocytes showed a reduced survival. In primary astrocytes, HMGB-1 exposure induced a dose-dependent NFkB activation and reactive gliosis; however astroglial response to HMGB1 required the presence of microglia. Loss of function studies showed that the HMGB1 effects are TLR2-TLR4 dependent and partially RAGE-dependent. In addition, HMGB-1 application on astrocytes induced TREM-2 expression. Finally, in vivo NFkB blockage with sulphazalazine significantly reduced reactive gliosis and neuronal degeneration induced by focal brain ischemia. We conclude that DAMP HMGB-1 has a major role in the propagation of proinflammatory response but also acts directly on the surviving neurons after focal brain injury. Supported by grants: PICT2012-1424; PICT2015-1451; UBACYT; PIP CONICET.

MODULATION OF EXPRESSION AND ACTIVITY OF P-GLYCOPROTEIN BY THE PROGESTIN NOMEGESTROL ACETATE IN HEPG2 CELLS. INVOLVEMENT OF MEMBRANE PROGESTERONE RECEPTOR.

GUILLERMO NICOLÁS TOCCHETTI (1,2), JUAN PABLO RIGALLI (1,2), CAMILA JULIANA DOMÍNGUEZ (1), FELIPE ZECCHINATI (1), MAITE ROCÍO ARANA (1), MARÍA LAURA RUIZ (1), SILVINA STELLA MARIS VILLANUEVA (1), JOHANNA WEISS (2), ALDO DOMINGO MOTTINO (1)

(2) Department of Clinical Pharmacology and Pharmacoepidemiology, University of Heidelberg, Heidelberg, Alemania.

Introduction: Nomegestrol acetate (NMGA) is a synthetic progestin increasingly used for oral contraception. Due to long-term NMGA therapy, concurrent use with other drugs is highly feasible. P-glycoprotein (P-gp; ABCB1) is a key player in drug excretion. Alterations in its activity represent a common cause of drug-drug interactions (DDI). Up to date, there is scarce data about modulation of ABC transporters by NMGA.

Aims: (1) to evaluate the modulation of P-gp expression and activity by NMGA (0.5 – 500 nM) in the human hepatic cell line HepG2 and (2) to identify the underlying mechanisms.

Materials & methods: Protein expression was assessed by western blot and
corresponding mRNA by qRT-PCR. mRNA stability was evaluated using actinomycin D. Pgp activity was evaluated by quantifying the intracellular accumulation of the model substrate calcein by flow cytometry. Progesterone receptor (PR) and Gi protein were inhibited using RU486 and pertussis toxin, respectively. Membrane progesterone receptor a (mPRa) was knocked down using siRNA.

Results: NMGA (5, 50 and 500 nM; 48 h) increased P-gp protein expression (+83%, +77% and +93%, $p < 0.05$) with concomitant increase in P-gp activity. NMGA increased *ABCB1* mRNA expression (+34%, +35% and +36%, $p < 0.05$) without affecting its stability, suggesting a transcriptional mechanism. Regarding hepatic progestin receptors, NMGA mediated P-gp induction was not prevented by RU486, ruling out PR participation. By contrast, P-gp induction by NMGA was prevented by pertussis toxin and by mPRa knock down, confirming participation of both Gi protein and mPRa.

Conclusion: NMGA up-regulates P-gp expression and activity through a mPRa-Gi protein dependent transcriptional mechanism. This is the first reported genomic effect of a progestin on ABC transporters that is independent of the classical PR. The data suggest the possibility of DDI, potentially affecting the therapeutic efficacy of drugs coadministered with NMGA.

A PHYSIOPATHOLOGICAL STUDY OF THE MATURATIONAL CHANGES OCCURRED IN HUMAN AND RHESUS MONKEY TESTIS FROM BIRTH TO PUBERTY - TRANSCRIPTIONAL AND EPIGENETIC MODIFICATIONS

PAULA ALIBERTI

Servicio de Endocrinología, Hospital de Pediatría Garrahan, Buenos Aires, Argentina.

To date, data regarding the maturational changes occurring in primate testes is poor, mainly due to the scarce studies in non-human primates and the limited normal human testes available. In contrast to primates, where a long period exists between birth and puberty, in rodents, childhood is practically non-existent making it inappropriate to extrapolate testicular development studies between species. For all this, our objective is to carry out a thorough analysis of the histological, transcriptional and epigenetic modifications of the human and Rhesus monkey testis from late fetal to pubertal subjects and contrast it with Disorders of Sex Development.

Leydig cell differentiation stages will be analyzed in depth, focusing on their morphological and gene expression changes (LHCGR, STAR, CYP11A1, HSD3B2, CYP17A1, HSD17B3, SRD5A1, SDR5A2, AKR1C1-4, HSD17B6, DLK1, AR) and insulin-like factors (IGFs) will be studied as possible regulators at prepuberty. The primary testicular androgen synthesis pathway (either front or back-door) will be investigated throughout postnatal life.

Patients with Androgen Insensibility Syndrome are excellent models to study the androgenic actions in the human testis. A comparison of the expressed genes and histological characteristics, focusing on germ cells differentiation and malignization (TSPY, MAGE-A4, OCT4, KIT, GFRA1), would help elucidate the role of androgens at prepuberty.

The Rhesus monkey is an excellent experimental model to determine the testicular transcriptome of the juvenile primate. The first gonadotropin associated changes in testicular gene expression produced by an in vivo induction of puberty (FSH+LH for 2 and 4 days) will be determined, as well as their regulation by miRNAs.

This plan uses: RT-qPCR, Western Blot, RNA-Seq, miRNA-Seq, bioinformatic pipelines, pathway analysis software, human primary cell and organotypic culture, immunohistochemical staining, steroid extraction and

concentration determination by HPLC-MS/MS.

ADENOVIRUS-MEDIATED HUMAN AQUAPORIN-1 EXPRESSION IN HEPATOCYTES IMPROVES LIPOPOLYSACCHARIDE-INDUCED CHOLESTASIS.

JULIETA MARRONE, MAURO DANIELLI, CÉSAR I. GASPARI, RAÚL A. MARINELLI

Instituto de Fisiología Experimental (IFISE), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Facultad de Ciencias Bioquímicas y Farmacéuticas, Universidad Nacional de Rosario (UNR), Rosario, Santa Fe, Argentina.

Lipopolysaccharides (LPS) are known to cause cholestasis in sepsis. There is evidence that a defective expression of canalicular aquaporin water channels contributes to bile secretory failure in LPS-induced cholestasis. Thus, we studied whether the hepatic adenovirus-mediated transfer of human aquaporin-1 gene (*haqp1*) can improve the cholestasis induced by LPS. Adenoviral vector encoding hAQP1 (AdhAQP1) or control vector was administered to rats by retrograde intrabiliary infusion. Hepatocyte canalicular hAQP1 expression was assessed by liver immunostaining and immunoblotting in purified plasma membranes.LPS significantly reduced bile flow and biliary bile salt (BS) excretion by 30% and 45%, respectively. AdhAQP1-treatment normalized both bile flow and biliary BS excretion in LPS-induced cholestasis. Moreover, markedly elevated serum BS levels in cholestatic rats, were almost restored with the AdhAQP1 hepatic transduction (control(C):34±4;C+AdhAQP1:29±6;LPS:114±11*;LPS+AdhAQP1:58±12 μM; *P<0.05).Bile flow and serum or biliary BS in normal rats were not significantly altered by AdhAQP1. AdhAQP1-treatment unaffected the downregulated protein expression of canalicular bile salt export pump (BSEP/ABCB11) in cholestasis, However, AdhAQP1 delivery recovered the biliary output of an intravenous tracer dose of [^{3}H]taurocholate (C:20.1±1.4;C+AdhAQP1:18.8±1.6;LPS:7.3±2.1*;LPS+AdhAQP1:17.1±2.7 cpm.10^{-3}; *P<0.05), thus suggesting an improvement of BSEP transport activity. These may be associated to the finding that hAQP1 expression restores reduced canalicular cholesterol content(C:0.25±0.01;C+AdhAQP1:0.26±0.02;LPS:0.18±0.01*;LPS+AdhAQP1:0.26±0.02 μmol cholesterol/mg protein; *P<0.05).Our data suggest that the adenovirus-mediated hepatocyte hAQP1 expression improves LPS-induced cholestasis in rats by stimulating the BSEP/ABCB11-mediated biliary BS excretion; a finding that might contribute to the understanding and treatment of sepsis-associated cholestatic diseases.

A NEW ROLE FOR LYSOPHOSPHATIDIC ACID IN VASCULAR PROCESSES AT THE MATERNAL-FETAL INTERFACE DURING EARLY GESTATION.

Successful implantation requires that the invading trophoblast acquires an endovascular phenotype and remodels uterine spiral arteries. Defects in this mechanism correlate with obstetric complications as implantation failure and preeclampsia. Lysophosphatidic acid (LPA) participates in embryo implantation and contributes to vascular physiology in different biological systems. However, the role of LPA on vascular processes at the implantation site has not been investigated. We adopted an *in vitro* and an *in vivo* pharmacological approach to study LPA action on trophoblast endovascular response and uterine transformation. The HTR-8/SVneo cell line (H8) was used to model the acquisition of the trophoblast endovascular phenotype. LPA (10 μM) increased H8 tube formation (6h), migration (wound healing, 18h) and proliferation (MTT assay, 48h) ($p<0.05$). By using selective antagonists, we showed that enhanced tubulogenesis was mediated by LPA3 receptor. In addition, COX-2 and iNOS pathways participated in LPA-stimulated tubulogenesis, being nitric oxide the last effector. When we investigated if the master hormones that orchestrate crucial events at the implantation sites, modulate trophoblast angiogenesis via LPA/LPA3, we observed that estradiol (10^{-5} M) + progesterone (10^{-7} M) increased H8 tube formation via LPA3 ($p<0.05$). The interaction between the trophoblast and the endothelium is relevant during the remodeling of the spiral arteries. We observed that trophoblast LPA-triggered secreted factors increased the migration of the EA.hy926 endothelial cell line ($p<0.05$). Finally, the administration of a selective LPA3 antagonist to Wistar rats in day 5 of gestation increased the rate of embryo resorption (60%) associated to macro and micro-

vascular defects. Our results demonstrate a new role for LPA during spiral artery remodeling at the maternal-fetal interface, and could help to understand obstetric complications as implantation failure and preeclampsia.

THE ROLE OF THE DENTATE GYRUS AND PERIRHINAL CORTEX IN PATTERN SEPARATION OF NON-SPATIAL MEMORIES

MAGDALENA MIRANDA, FACUNDO MORICI, DINKA PIROMALLI GIRADO, FRANCISCO GALLO, NOELIA WEISSTAUB, PEDRO BEKINSCHTEIN

Laboratorio de Memoria y Cognición Molecular, Instituto de Neurociencia Cognitiva y Traslacional (INCYT), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Universidad Favaloro, Instituto de Neurociencia Cognitiva (INECO), Buenos Aires, Argentina.

Successful memory involves not only remembering information over time but also keeping memories distinct and less confusable. The ability to separate the components of memories into distinct memory representations relies on pattern separation, a computational process by which differences are amplified to disambiguate similar events. Despite the importance of this mnemonic function, the molecular mechanisms and signals necessary for the behavioral manifestations of this process remain unknown. Although pattern separation has been localized to the dentate gyrus (DG) of the hippocampus and shown to occur in a spatial domain, this cognitive function is thought to take place also during processing of other types of information. The perirhinal cortex (PRH) is involved in the acquisition and storage of object memories, and it was shown to be crucial for the resolution of tasks with ambiguous features. However, there is some debate on whether the DG participates in pattern separation of non spatial representations. Here we use a modified version of the object recognition task and manipulated the load of pattern separation during encoding of the task. We show that two plasticity-related proteins, BDNF and Arc, are required for pattern separation of object memories in the PRH and that Arc is also required in the DG for this process. In addition, while exogenous BDNF was able to enhance pattern separation when injected into PRH, it was not effective when infused within the DG. Finally, BDNF injected into PRH was able to rescue the memory deficit produce by blockade of Arc in the DG. These results reveal a complex interaction between plasticity mechanisms in the PRH and the DG for non spatial pattern separation and posit the Prh as the key structure where unique object representations are stored.

MATERNAL DIETARY INTAKE OF LIPOIC ACID DURING PREGNANCY AND LACTATION INFLUENCES METABOLISM AND WEIGHT GAIN IN THE WISTAR RAT OFFSPRING.

MARIA BELEN RABAGLINO, FRANCISCO ESMORIZ, MARIANELA VARA MESSLER, MARIA JOSÉ MOREIRA ESPINOZA, DANTE BELTRAMO

Centro de Excelencia en Productos y Procesos de Córdoba (CEPROCOR), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Ministerio de Ciencia y Técnica, Córdoba, Argentina

Lipoic acid (LA) is an antioxidant that easily diffuses trough biological membranes after oral intake. The anti-obesogenic properties of LA are given by a modification of genes related with metabolism and energy expenditure. On the other hand, the fetal period is characterized by strong changes in gene expression that if altered, can influence the phenotype of the organism in the postnatal life. The objective was to determine the effect of maternal intake of LA -during the period that the appetite regulatory network is established in the fetal rat- on lipid deposition and metabolism in the adult offspring. Pregnant Wistar rats were fed ad-libitum with ground food + LA (200 mg/kg) from day 14 of gestation to day 20 of lactation (n=3) or ground food (n=3). After litter reduction, 12 males and 12 females born from the LA fed rats (LA, n=24) or not (Control, n=24) were used to evaluate weekly body weight, food intake, plasmatic levels of cholesterol, glucose and triglycerides and IL6 levels in liver homogenates trough ELISA at 3 months of age. The effect of group was analyzed by t-test for each gender. Compared to Control rats, overall body weight for AL rats was 11.4% heavier for males ($p<0.001$) and 7.5% heavier for females ($p=0.01$), and daily food intake tended to be higher for AL rats ($0.05>p<0.1$). However, LA rats presented lower liver weight ($p=0.024$), lower rate of liver weight/body weight ($p=0.02$) and lower levels of IL6 in liver (males: 2.1± 0.03 pg/mlvs 2.5± 0.07 pg/ml, $p=4.1x10^{5}$; females: 1.2± 0.03 pg/mlvs 1.7± 0.02 pg/ml, $p=3.5x10^{-8}$). Also, AL rats had lower triglycerides levels (males: 74.3± 23.6mg/dlvs 136.6± 25.7mg/dl, $p=0.036$; females: 94.6± 13.0mg/dlvs 125.3± 9.7mg/dl, $p=0.031$) and no differences were detected in cholesterol and glucose levels. In conclusion, these results suggest that maternal intake of LA improves energy expenditure in the offspring, probably stimulating protein synthesis in the muscle and reducing fat deposition.

SAIC- FUNDACION GADOR AWARD

THE SUBPOPULATION OF GABAERGIC PROOPIOMELANOCORTIN NEURONS OF THE HYPOTHALAMUS REGULATE ENERGY BALANCE

MILAGROS TROTTA, RAMIRO ALSINA, VIVIANA FLORENCIA BUMASCHNY

Instituto de Fisiología y Biofísica "Bernardo Houssay" (IFIBIO-Houssay), Grupo de Neurociencia de Sistemas, Facultad de Medicina, Universidad de Buenos Aires, Consejo Nacional de Investigaciones Científicas y Técnicas, Buenos Aires, Argentina.

Obesity is an epidemic disease that affects 600 million adult people worldwide, which is a consequence of alterations in energy balance. The arcuate nucleus of the hypothalamus is a key area that integrates peripheral signals of energy status and regulates energy homeostasis by projecting to second order neurons. Arcuate proopiomelanocortin (POMC) neurons inhibit food intake and increase energy expenditure. Pomc mutant humans and mice develop early onset severe obesity, what demonstrates that POMC neuropeptide is one of the main regulators of energy balance. Some studies reveal the existence of subpopulations of POMC neurons secreting the antagonistic neurotransmitters glutamate or GABA, but their physiological roles and targets remain to be dissected. In order to elucidate the role of GABAergic POMC neurons, we intercrossed a reversible Pomc knockout mouse line (in which Pomc expression can be conditionally reactivated), with another line bearing a GABA-specific Cre driver. These mice developed obesity but, after the rescue of Pomc in GABAergic neurons, they normalized food intake and metabolic efficiency. Notably, females significantly decreased their body weight and reached an energy balance that matches that of lean control mice. Surprisingly, these physiological improvements were achieved with the recovery of Pomc expression in only 25% of total hypothalamic POMC neurons. Immunohistochemical analysis showed that GABAergic POMC neurons preferentially project to the dorsomedial hypothalamus (DMH), a nucleus that induces food intake by releasing NPY. In order to emphasize the role of GABAergic subpopulation, by using another mouse line expressing a ubiquitous Cre, we found that the partial rescue of Pomc, unrestricted to any subpopulation, failed to improve body weight, food intake or metabolic efficiency. Altogether, these results show that GABAergic POMC neurons have a major role in the establishment of energy balance, probably, through an arcuate-DMH circuit.

CAFETERIA DIET INDUCES PROGRESSIVE AND DIFFERENTIAL CHANGES IN BRAIN MECHANISMS INVOLVED IN FOOD INTAKE CONTROL OVER TIME

GISELA PAOLA LAZZARINO (1), MARÍA FLORENCIA ANDREOLI (INSTITUTO DE SALUD Y AMBIENTE DEL LITORAL (1), MARÍA FLORENCIA ACUTAIN, ROCIO SCHUMACHER, CORA STOKER, JORGE GUILLERMO RAMOS.

Instituto de Salud y Ambiente del Litoral (ISAL), Universidad Nacional del Litoral (UNL), Consejo Nacional de Investigaciones Científicas y técnicas (CONICET), Santa Fe, Argentina.

We aim to determine the effects of Cafeteria diet (CAF), rich in palatable and energy dense foods, on the expression of key genes of the brain reward system (RW) in the short and long term. Female Wistar rats were fed chow or CAF for 4 or 11 weeks. Animals were sacrificed and 2 regions of the Accumbens Nucleus (NA – Core, NAC; and shell, NAS), Ventral Pallidum (VP) and Ventral Tegmental Area (VTA) were dissected. Serum leptin was assessed by RIA. mRNA expression of genes of the dopaminergic and GABAergic pathway, and the leptin receptor (ObRb) was evaluated by qPCR in the nuclei. Data was statistically analyzed by two-way ANOVA followed by Tukey post-test. Four weeks of CAF increased energy intake and adiposity, not affecting circulating leptin or body weight. In VTA, 4 weeks of CAF increased the expression of the dopamine active transporter (DAT) and decreased both isoforms of the enzyme involved in the synthesis of GABA (glutamate decarboxylase, GAD 1 and 2), without altering tyrosine hydroxylase (TH) expression. CAF decreased dopamine receptor (DR) 2 expression in NAS and increased DR1 levels in NAC. Also, CAF increased GAD2 levels in VP. After 11 weeks of CAF, animals sustained the hyperenergetic intake and further increased adiposity, leading to hyperleptinemia and higher body weight, only concomitant to an increased expression of ObRb in VTA. Our results indicate that the higher energy intake of CAF animals in the short-term would respond to hedonic mechanisms, given by molecular deregulations in the RW. The palatability of the diet could lead to a hypodopaminergic state, as DAT expression increase in VTA and DR2 decrease in NAS. Besides, the increment in GAD2 expression in VP indicates an inhibitory GABAergic input to dopaminergic and GABAergic VTA neurons that may, inhibit dopamine and GABA release, in line with the low expression levels of GAD1 and GAD2. Conversely, in the long-term the hypercaloric intake could respond to an altered homeostatic control.

METFORMIN PROMOTES ß-CATENIN AND E-CADHERIN PLASMA MEMBRANE TRANSLOCATION

GASTON FEDERICO AMABLE (1), EDUARDO MARTÍNEZ LEÓN (1), MARÍA ELISA PICCO (1), LAURA INÉS ANAYA (2), OSVALDO REY

Colorectal cancer (CRC) is the third most common diagnosed cancer globally and the third most frequent cause of cancer-related deaths in Argentina. In colorectal tumors the first oncogenic mutation provides selective advantage to the epithelial cell that multiplies and generates a microadenoma. In the majority of sporadic colorectal tumors these "initiatory" mutations frequently occur in genes associated to the Wnt pathway. Subsequent mutations in other genes, such as TP53, PTEN, SMAD4, KRAS and PIK3CA are followed by clonal expansion of transformed cells. Despite advances in surgical techniques, improved chemotherapy and early detection, CRC is still associated with a relatively poor prognosis. At least 40% of patients who undergo resection of the primary tumor die within 5 years. CRC is a major health problem demanding new approaches for its prevention and treatment.

Several lines of evidence indicate that metformin, a first-line oral anti-diabetic agent for type 2 diabetes, has an antitumor effect. For example, a recent meta-analysis that included 23.255 participants from six cohort studies revealed that diabetic patients with CRC taking metformin achieved an estimated overall survival benefit of 44% compared with non-metformin users. The mechanism mediating this effect has not been elucidated.

Results from our laboratory show that metformin inhibits the proliferation of human cells derived from primary adenocarcinoma of the colon by a mechanism that involves ß -catenin and E-cadherin. Specifically, we found that metformin: 1- inhibits the phosphorylation of ß-catenin Ser552, 2- promotes the plasma membrane redistribution of ß-catenin and E-cadherin, 3- inhibits ß-catenin-mediated transcription, and 4- inhibits cell's motility. Overall, our studies reveal two novel metformin targets and suggest a mechanism by which this anti-diabetic drug interferes with CRC development.

VMP1-RELATED AUTOPHAGY CONFERS RESISTANCE TO TREATMENT AND HYPOXIA IN TUMOR CELLS FROM HUMAN GASTROINTESTINAL ADENOCARCINOMAS

CINTIA BETIANA CATRINACIO (1), ALEJANDRO ROPOLO (1), MATIAS EZEQUIEL RODRIGUEZ (1, 2), MARÍA INÉS MOLEJÓN (1), TAMARA ORQUERA (1), VIVIANA RIVAROLA (2), MARÍA INÉS VACCARO (1)

(1) Instituto de Bioquímica y Medicina Molecular (IBIMOL). Subsede Fisiopatología. CONICET. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Buenos Aires, Argentina. (2) Departamento de Biología Molecular. Universidad Nacional de Río Cuarto, Río Cuarto, Córdoba, Argentina.

Autophagy is an evolutionarily conserved degradation process of cytoplasmic cellular constituents. It has been suggested that autophagy plays a role in both tumor suppression and tumor progression. Tumor cells develop autophagy as an adaptation to stressful conditions such as hypoxia and treatment. VMP1 is a transmembrane protein necessary for autophagy induction. Previously, we demonstrated that the PI3K-AKT1 signaling pathway activates the GLI3-p300 complex that binds to the VMP1 promoter to regulate its activity in pancreatic tumor cells. Here we characterize new molecular pathways mediated by VMP1, by which gemcitabine, in human pancreatic tumor cells and hypoxia, in colon cancer cells, can trigger autophagy and resistance to treatment. We demonstrate that gemcitabine requires VMP1 expression to induce autophagy in highly resistant pancreatic cancer cells PANC-1 but not in less resistant BxPC-3 cells. Analysis of the mechanisms identified E2F1 as an effector of gemcitabine. We show that E2F1 regulates the expression and promoter activity of VMP1. Moreover, our study demonstrates that the pharmacological stabilization of HIF-1α significantly increases VMP1-related autophagy through binding to hypoxia responsive elements in VMP1 promoter. Moreover, HIF-1α-induced autophagy increases cell survival after photodynamic therapy of CaCo2 and Sw480 cells. Chromatin immunoprecipitation assays showed that E2F1 and HIF-1 bind to the VMP1 promoter in PANC-1 and Caco2 cells, respectively. Finally, we demonstrate that downregulation of VMP1 expression and pharmacological modulation of autophagy sensitize cells to antitumor treatments. We described two novel transcriptional regulation mechanisms of autophagy mediated by HIF-1α/VMP1 and E2F1/VMP1 pathways that may explain resistance in colon and pancreas adenocarcinomas. These findings are of high clinical relevance since they integrate VMP1-related autophagy to the complex network of events involved in tumor cell resistance.

CYTOKINE-INDUCED ENDOPLASMIC RETICULUM STRESS IN β-CELLS IS AMELIORATED BY COMPOUND A

LUZ ANDREONE (1), MARÍA LAURA GIMENO (1), FLORENCIA FUERTES (1), ANDRÉS E BARCALA TABARROZZI (1), LAURA ARIOLFO (1), ANA CLARA LIBERMAN (1), SARAH GERLO (2), KAROLIEN DE BOSSCHER (2), MARCELO JAVIER PERONE (1)

Type 1 diabetes (T1D) is a T cell-mediated autoimmune disease that selectively destroys insulin producing β-cells. ER stress and subsequent insulin secretory deficiency in β-cells precede the onset of autoimmune diabetes. Pro-inflammatory cytokines (IL-1+IFN-; CYT) signaling leads to activation of ER stress in β-cells. We reported that Compound A (2-(4-acetoxyphenyl)-2-chloro-N-methyl-ethylammonium chloride; CpdA), a dissociative glucocorticoid receptor (GR)-ligand, is an effective modulator of T and dendritic cells. The aim of this study was to explore the beneficial effects of CpdA on CYT-induced β-cell ER stress; the classic GR-ligand dexamethasone was used for comparison. CpdA significantly reduced CYT-induced NO secretion by the insulinoma INS-1E cells ($p<0.01$). CpdA treatment inhibited CYT-triggered IB phosphorylation protecting its degradation and hampering, in consequence, NF-B nuclear translocation in INS-1E cells ($p<0.05$). CpdA treatment impaired eIF2α phosphorylation enhancement and the increase of ER stress protein markers expression, such as ATF4 and CHOP, in CYT-challenged INS-1E cells ($p<0.05$). The expression of chaperones involved in protein folding and processing (PDI, ORP150) was enhanced in the presence of CpdA ($p<0.05$). CpdA administration (i.p.) to NODscid mice adoptively transferred with diabetogenic splenocytes (from diabetic NOD mice) led to a delay of disease onset ($p<0.001$ vs control). CpdA-treated mice showed a reduction in islet leukocytes infiltration and preserved insulin expression in comparison with veh-treated group, assessed by immunohistochemistry. In summary, we demonstrate that CpdA directly improves the UPR attenuating ER stress in -cells challenged by CYT. The latter together with our previous reports on immune cells modulation, might warrant the administration of CpdA as a novel therapeutic strategy with dual activity on autoimmune diabetes.

Protein kinase D1 (PKD1) is a serine/threonine kinase that is activated by pharmacological agents such as phorbol esters and physiological stimuli including GPCRs stimulation, growth factors and oxidative stress among others. During the interphase PKD1 play an important role in the regulation of a remarkable variety of biological processes including signal transduction, cell migration, differentiation, proliferation and the development of different types of cancer. Nevertheless very little is known about the role of this kinase during other phases of the cell cycle including cell division.

Cell division is a complex process regulated by many macromolecules that are controlled by kinases and phosphatases which in turn are regulated by mitotic signaling pathways that remain poorly defined.

Hence, the principal aim of this study was to determine whether PKD1-mediated signaling contributed to mitosis regulation. We employed cells lines expressing eGFP or eGFP-tagged PKD1, under the control of an inducible promoter, to examine by real-time imaging of single-cells maintained under physiological conditions the role of PKD1 during mitosis. This methodology was complemented by indirect immunofluorescence of fixed cells, Western blot and flow cytometry (FACS). Using these methodologies we obtained the following results: 1- Catalytic active PKD1 colocalizes with mitotic spindle, centrosomes and midbodies 2- Over-expression of the kinase retards mitosis progression, specifically lengthening metaphase duration by 50% ($p<0.001$) 3- Inhibition of PKD1 activity prior to entry into mitosis stops cell cycle progression (Coefficient of variation (CV)<8, 0) 4- Cells that were incubated in the presence of PKD1 specific inhibitors, after entrance into the mitotic phase, do not progress through the cycle preventing the completion of mitosis (CV<8.0). These data, therefore, indicates that PKD1 regulates the progression of cellular mitosis.

RSPO3, A POSITIVE WNT PATHWAY MODULATOR, INDUCES MESENCHYMAL FEATURES IN MAMMARY CELLS AND IS DIFFERENTIALLY EXPRESSED BY THE BASAL-PROGENITOR SUBPOPULATION AND TRIPLE-NEGATIVE BREAST CANCERS.

Abstract: Breast cancer is a leading cause of death among women worldwide. R-spondin3 (RSPO3) is a member of a family of secreted proteins that enhance canonical and non-canonical Wnt signaling pathways. Due to their Wnt-potentiating activity, RSPOs have been postulated as stem cell growth factors and are implicated in diverse processes like embryonic development, tissue differentiation and human diseases including cancer. However, the role of RSPO3 in mammary gland and breast cancer development remains unclear. We identified MMTV insertion sites close to Rspo3 gene, promoting its overexpression and the consequent tumor formation. Therefore, our goal was to investigate the biological function of RSPO3 in normal and tumor mammary cells. Recently, we found that RSPO3 is expressed in the basal stem cell-enriched compartment of normal mouse mammary glands whereas it is absent from committed mature luminal cells, in which exogenous RSPO3 impairs lactogenic differentiation. In addition, RSPO3 knockdown in basal-like mouse mammary tumor cells reduces canonical Wnt signaling, epithelial-to-mesenchymal transition-like features, migration capacity, and tumor formation in vivo. Importantly, RSPO3 overexpression, which is associated with leucine-rich repeat-containing G-protein coupled receptors 4, 5 and 6 (LGR4-6) levels, highly correlates with the basal-like subtype among breast cancer patients, particularly with triple-negative claudin-low tumors. Thus, we identified RSPO3 as a novel key modulator of breast cancer development that may become a potential target for treatment of the basal subtype which lacks efficient therapeutic options to date.

ACQUISITION OF METASTATIC PROPERTIES IN CARCINOMA CELLS: IDENTIFICATION OF A NOVEL PHOSPHORYLATION SITE IN CIP4 REGULATED BY THE PROTEIN COMPLEX AKAP350/PKA WITH A CENTRAL ROLE IN TUMOR INVASIVENESS.

Cancer malignancy is associated to cancer cells capacity to invade neighboring and distant tissues. Carcinomas are defined by their epithelial origin and constitute the most common type of cancer. Carcinoma metastasis requires epithelial derived tumor cells to acquire a mesenchymal phenotype (EMT). During EMT, cells lose contacts due to ablation of E-cadherin and acquire increased motility. CIP4 is a cdc42 effector essential for EMT, whose expression levels correlate with cell invasiveness in breast cancer. CIP4 structure and role in membrane plasticity has been characterized; however, how CIP4 function is regulated remains elusive. We have previously shown that CIP4 is a PKA substrate that interacts with AKAP350, and that this interaction is essential for CIP4 promotion of hepatocellular carcinoma (HCC) cell migration. The aim of this study was to evaluate if CIP4 pro-invasive ability is regulated via phosphorylation by PKA. Using in silico analysis and in vitro phosphorylation assays, we characterized that CIP4 has a unique PKA phosphorylation site (CIP4T225). Expression of its phosphomimetic mutant CIPT225E decreased E-cadherin levels (-51%*) and increased migratory efficiency (+44%*) in HCC cells. Conversely, expression of CIP4 not phosphorylatable mutant CIP4T225A inhibited HCC cell migration (-43%*). Pharmacological inhibition of PKA decreased HCC migratory efficiency in control (-40%*), but not in CIP4T225E or CIP4T225A cells. Transwell invasion assays showed that HCC invasiveness was increased in CIP4T225E (+800%*) and inhibited in CIP4T225A (-90%*) cells. In vivo studies confirmed

the in vitro results, showing increased formation of metastatic nodules in lungs of athymic mice injected with CIP4T225E cells. These findings unveil a novel-signaling pathway involving CIP4T225 phosphorylation by PKA as a crucial event in the acquisition of metastatic properties in HCC cells. We are currently evaluating this regulatory pathway in breast cancer cells. *p<0,05

HIGH RAC3 EXPRESSION LEVELS ARE REQUIRED FOR INDUCTION AND MAINTAINING OF CANCER CELL STEMNESS.

LAURA CAROLINA PANELO (1), MILENI SOARES MACHADO (1), FELIPE MARTIN JAWORSKI (2), MARÍA FERNANDA RUBIO (1), MARÍA CECILIA LIRA (1), FRANCISCO DAMIÁN ROSA (1), ALEJANDRO JORGE URTREGER (3), ELBA SUSANA VÁZQUEZ (2), MÓNICA ALEJANDRA COSTAS (1)

RAC3 is a transcription coactivator, usually overexpressed in several tumors and required to maintain the pluripotency in normal stem cells. Although its involvement in tumor development has been amply investigated its potential role inducing or maintaining cancer cell stemness has not been determined.

In this work we studied the association between RAC3 overexpression and cancer cell stemness and the capacity of this protein to induce cancer stem properties in non tumoral cells.

We performed in vitro and in vivo experiments using two strategies: by overexpressing RAC3 in the non tumoral cell line HEK293 by transfection with a RAC3 expression vector and by silencing RAC3 in the human colorectal epithelial cell line HCT116 with a specific shRAC3. Furthermore, we analysed public repository microarrays data from 19 human colorectal tumors in different developmental stages.

In the microarrays analysis, we found that RAC3 overexpression was mainly associated to early and advanced stages of colon cancer ($p \leq 0,05$), involving increased expression of RAC3, Vimentin, cMYC, OCT4 and Nanog mRNA ($p \leq 0,05$). In turn, RAC3 silencing in HCT116 induced diminished tumoral properties and cancer stem cells (CSC) as determined by Hoechst efflux, tumorspheres and clonogenic growth ($p \leq 0,01$), which correlated with decreased Nanog and OCT4 expression ($p \leq 0,05$). Moreover, RAC3 overexpression was mainly associated to CD133+ side population ($p \leq 0,05$). In non tumoral cells, RAC3 overexpression induced tumoral transformation; mesenchymal phenotype, migration, invasion, metalloproteinases production ($p \leq 0,05$), proliferation under low serum ($p \leq 0,05$), clonogenic tumorspheres growth ($p \leq 0,05$), OCT4 and Nanog expression ($p \leq 0,05$). Moreover, these transformed cells generated tumors in vivo.

Our results demonstrate that RAC3 is associated to cancer stem phenotype not only maintaining the stemness in cancer cells, but also inducing cancer stem like cells by overexpression in non tumoral cells.

ENGINEERING AN ENDOGENOUS LECTIN TO TREAT AUTOIMMUNE DISEASES.

Glycosylation is a highly regulated process capable of modulating the fate and function of T cells. In the present work, we studied how differential glycosylation can modulate regulatory (Treg) and effector T (Teff) cell function and capitalized on this information for the design of a novel therapeutic strategy for autoimmune diseases. We found that Galectin-1 (Gal1) treatment ameliorates the clinical symptoms of mice bearing experimental autoimmune encephalomyelitis (EAE) ($p<0.05$), animal model of multiple sclerosis (MS), by dampening Th1 and Th17 responses while enhancing the Treg cell compartment ($p<0.01$). Mechanistically, Tregs but not Teff cells, are protected from Gal1-induced apoptosis ($p<0.001$) through differential N-glycan branching and α2,6 sialylation (α2,6SA) of cell surface glycoproteins. In MS patients, we found that during the relapse phase of the disease they show low levels of circulating Gal1 ($p<0.001$), and identified a subpopulation of CD4 T cells –absent during the remitting phase– characterized by low levels of α2,6SA ($p<0.001$) and susceptibility to Gal1-induced apoptosis ($p<0.001$). To capitalize on this information for therapeutic purposes, we studied physicochemical properties that hinder translation of this immunoregulatory lectin to clinical settings. We found that Gal1-induced apoptosis of T cells is impaired by both acidic ($p<0.05$) and oxidative conditions ($p<0.01$), typical hallmarks of inflammatory settings. Thus, we genetically engineered Gal1 protein to generate stable mutants capable of circumventing these limitations. These mutants showed enhanced capacity to induced apoptosis of activated T cells ($p<0.05$), IL-10 secretion by T cells ($p<0.001$) and IL-27 secretion by DCs ($p<0.001$). Finally, these mutants showed enhanced therapeutic potential in mouse models of MS (EAE) ($p<0.001$), arthritis (CIA) ($p<0.01$) and colitis (TNBS-IBD) ($p<0.05$). Our findings provide novel therapeutic strategies for treating a broad range of autoimmune diseases.

Pirovano", Ciudad Autónoma de Buenos Aires, Argentina. 4 Instituto de Investigaciones Biotecnológicas (IIB-UNSAM), Gral. San Martín, Buenos Aires, Argentina.

T cell-mediated response has been proven to play a major role in controlling *T. cruzi* infection and parasite burden. It also seems to be involved in the progression from asymptomatic Chagas disease (ACD) to chronic Chagas cardiopathy (CCC) in chronically infected patients. However, the complexity of the parasite-host interactions hampers the identification and characterization of T cell activating epitopes. We approached this issue by combining *in silico* and *in vitro* methods to interrogate patients' T cells specificity.

The sequences of the 53 *T. cruzi* proteins annotated on the Immune Epitope Database (IEDB) were split in all possible 15-aminoacid long peptides, and 50 candidate peptides were selected using a bioinformatic pipeline (MHCpan, MHCIIpan, PopCover), based on conservation between annotated parasite strains, non-identity with *H. sapiens* sequences, class I and II MHC molecules binding affinity and HLA polymorphic variants coverage. Candidate peptides were randomised in 5 pools of 10 peptides each, which were used to challenge peripheral blood mononuclear cells (PBMC) from chronic Chagas disease patients, in IFN-γ ELISPOT assays. Positive pool-patient pairs were re-assayed in a single-peptide fashion to identify individual active peptides. A total of 7 peptides induced IFN-γ secretion in at least one patient's PBMC, 4 of which do not contain any previously described epitope. In combination, response to these peptides covered 33% of the patients cohort in this study (n=51), 40% of the ACD group (n=25) and 27% of the CCC group (n=26). IFN-γ ELISPOT with CD8- or CD4-depleted PBMC showed that 6 of the peptides contain MHC class II epitopes, while 1 contains an MHC class I epitope. The fact that most of these subjects responded to 1 or 0 peptides is a strong sign of HLA restricted epitopes. In summary, we predicted, validated and characterized 7 T cell-activating peptides from *T. cruzi* antigens, 4 of which contain epitopes first described in this work.

THE BTK INHIBITOR IBRUTINIB IMPAIRS THE INNATE IMMUNE RESPONSE AGAINST Mycobacterium tuberculosis MEDIATED BY MACROPHAGES AND γδ T CELLS.

The Bruton's Tyrosine Kinase (Btk) inhibitor, ibrutinib (ibru), was recently approved for the treatment of Chronic Lymphocytic Leukemia (CLL) patients. Previously we found that ibru affected macrophage polarization and TNF-α secretion in response to *M. tuberculosis* (Mtb). Considering that ibru is being introduced in countries with high incidence rates of tuberculosis (TB), such as Argentina, we aimed to extend the study of the effect of ibru on the immune response to Mtb mediated by macrophages and γδ T cells, which are central players in TB innate immunity.

Macrophages were differentiated by culturing human monocytes with M-CSF. TNF-α, IL-8 and IL-10 secretion were measured by ELISA after macrophage stimulation with irradiated Mtb, Pam3CSK4 or LPS for 24h. Phospho-p65 of NFkB was evaluated by Western blot. Phagocytosis of Mtb-FITC by macrophages was evaluated by flow cytometry. Bacillary loads were determined by colony-forming units assay. Human γδ T cells were purified by using MicroBead isolation kit and after 24h of Mtb stimulation, IFN-γ was evaluated by ELISA and CD69 expression by flow cytometry. Statistical significance was determined using the Friedman test and the Dunn's post-test.

We found that ibru significantly reduced TNF-α, IL-10 and IL-8 secretion (n=10, $p<0.05$) and diminished phospho-p65 (n=5, $p<0.05$) in response to Mtb. Moreover, ibru impaired TNF-α secretion by macrophages in response to LPS and Pam3CSK4 (n=10, $p<0.05$). Then, we found that ibru significantly enhanced Mtb phagocytosis (n=14, $p<0.05$) and preliminary results showed a slight increase in the bacillary loads obtained from ibru-treated macrophages. CD69 expression and IFN-γ secretion was impaired in ibru-treated γδ T cells in response to Mtb (n=8, $p<0.05$).

Our results suggest that the innate-immune response to Mtb might be compromised in ibru-treated patients. Thus, increased awareness should be taken during ibru treatment especially in countries with high incidence rates of TB.

SAFIS - CAMILIÓN DE HURTADO AWARD

SILENCING OF CARDIAC EPIDERMAL GROWTH FACTOR RECEPTOR REDUCES CARDIAC HYPERTROPHY OF ADULT SPONTANEOUSLY HYPERTENSIVE RAT.

MARÍA SOLEDAD BREA (1), ROMINA GISEL DÍAZ (1), DAIANA SABRINA ESCUDERO (1), JOSEFINA FUHR (1), ENRIQUE LEO PORTIANSKY (2), CLAUDIA IRMA CALDIZ (1), NÉSTOR GUSTAVO PÉREZ (1)

(1) Centro de Investigaciones Cardiovasculares Dr. Horacio E. Cingolani (CIC), Universidad Nacional de La Plata (UNLP), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET). (2) Laboratorio de Análisis de Imágenes, Facultad de Ciencias Veterinarias, Universidad Nacional de La Plata (UNLP), La Plata, Argentina.

Epidermal growth factor receptor (EGFR or ErbB1) is an integral membrane protein, that together with other members of the family, ErbB2 and ErbB4 are necessary for a normal adult heart function. EGFR transactivation was linked to pathological cardiac hypertrophy (PCH). Experimentally, its pharmacological inhibition prevented PCH. The objective of this study was to limit PCH by a specific and localized silencing of cardiac EGFR of spontaneously hypertensive rats (SHR) with small interference RNA (siRNA). Animals were treated with a sequence that inhibits EGFR expression (l-shEGFR, n=9) or with the non-silencing disordered sequence (l-shSCR, n=10) as control. To promote siRNA entry into the myocardium, it was integrated into the lentivirus genome and injected ($1x10^7$ TU / 200 µl) attwo sites of the anterolateral heart wall. After 30 days, animals were sacrificed and hearts removed. Heart left ventricle was weighted (LVW) and normalized to body weight (BW) and tibia length (TL). Morphometric analysis showed that LVW/BW and LVW/TL respectively were reduced in l-shEGFR (2.92 ± 0.05 mg/g and 20.25 ± 0.25 mg/mm) compared to l-shSCR group (3.15 ± 0.08 mg/g and 22.42 ± 0.57 mg/mm; $p<0.05$). This reduction was accompanied by a decrease of the myocytes cross sectional area:246.3 ± 20.6 μm^2l-shEGFR vs.298.33 ± 9.8 μm^2l-shSCR, ($p<0.05$), evaluated by hematoxylosin-eosin staining of LV histological sections. Since EGFR inhibition could reduce redox-sensitive pathways, myocardial lipid peroxidation (by thiobarbituric reactive substances, TBARS) and basal reactive oxygen species (ROS) were evaluated in both experimental groups. Both TBARS and ROS were reduced in LV myocardium of SHR injected with l-shEGFR

vs. l-shSCR ($p<0.05$). These results demonstrate that 1) normal EGFR expression is necessary to mediate cardiac hypertrophy, 2) suggest specific silencing of EGFR in the myocardium as an alternative therapeutic strategy for PCH treatment.

CARDIOVASCULAR MODIFICATIONS IN OVARIECTOMIZED RATS: ROLE OF THE SODIUM/PROTON EXCHANGER (NHE) AND THE SODIUM/BICARBONATE (NBC) COTRANSPORTER.

ALEJANDRO MARTÍN IBAÑEZ, MARÍA SOFÍA ESPEJO, SUSANA MOSCA, ERNESTO ALEJANDRO AIELLO, VERÓNICA CELESTE DE GIUSTI

Centro de Investigaciones Cardiovasculares Dr. Horacio E. Cingolani (CIC), Universidad Nacional de La Plata (UNLP), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), La Plata, Argentina.

During post menopause, women are exposed to an increased cardiovascular (CV) risk. Although the main cause seems to be the loss of estrogen, the precise intracellular modifications are still unknown. The sodium/proton exchanger (NHE) and the sodium/bicarbonate cotransporter (NBC) regulate intracellular pH (pH_i). NBC has two isoforms: electrogenic ($1Na^+/2HCO_3^-$; NBCe1) and electroneutral ($1Na^+/1HCO_3^-$; NBCn1). Hyperactivity of NHE and NBCn1 and down-regulation of NBCe1 are associated with several CV diseases. The aim of this work is to investigate the alterations of these transporters during the postmenopausal period, which could explain the increase in CV risk. Bilateral ovariectomy (OVX) was performed in 3 months old Wistar rats. Sham animals were generated by surgical incisions without ovariectomy. The increase in body weight and left ventricle mass was greater in OVX than in Sham. Systolic blood pressure was higher in OVX (122,29±3.06mmHg*, n=16; vs 117.45±1.85mmHg n=23). Cardiac function after an ischemia/reperfusion protocol showed a clear alteration in OVX (i.e. developed left ventricle pressure: 5.66±2.30% vs 21.01±5.36%; n=6, $p<0.05$). The OVX infarct size was 57.21±2.50%* vs 29.40±2.50% in Sham; n=6. NHE and total NBC activity were assessed during recovery from acidosis induced by an NH_4^+ pulse. NHE was hyperactive in OVX (dpHi/dt at pH_i 6.8, pH units/min: 0,083±0,008*, n=19 vs 0,061±0,006, n=16), whereas total NBC activity was not different between groups. NBCe1 activity measured in isolation (depolarization with 45 mM KCl) was decreased in OVX (ΔpH=0,076±0,013*; n=8 vs 0,149±0,018; n=9). Consistently, protein expression of NHE was greater and NBCe1 was lower in OVX compared to Sham. Interestingly, NHE activity measured in platelets was also greater in OVX (0,016±0,002*, n=13 vs 0,010±0,002, n=7), representing a valuable biological marker. We propose that the hyperactivity of NHE and NBCn1, accompanied with the decrease in NBCe1 activity could explain the cardiac dysfunctions found in OVX.

THE CALCIUM INFLUX THROUGH P2X RECEPTORS MODULATE THE BKCa CHANNEL ACTIVITY IN VASCULAR SMOOTH MUSCLE CELLS.

NICOLAS ENRIQUE, AGUSTIN ASUAJE, MELISA MONCADA, MARÍA VERÓNICA MILESI, PEDRO MARTIN

Instituto de Estudios Inmunológicos y Fisiopatológicos (IIFP), Universidad Nacional de La Plata (UNLP), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), La Plata, Argentina.

Human vascular smooth muscle cells (SMC) exposed to extracellular ATP (ATPe) evoked a transient inward ionic current, carried by Na+ and Ca2+, characterized by a fast activation followed by a peak current decrease. Among the different roles this Ca2+ influx could have on the SMCs, we focus on its possible functional coupling with the large conductance voltage and Ca2+ activated K+ channels (BKCa). Since this K+ channel has a high Ca2+ sensitivity, it could be activated by the ATP-induced-calcium-influx, producing hyperpolarization of SMC and subsequently modulate the contractile state of these cells.

Whole-cell patch clamp experiments were performed applying consecutives voltage protocols designed by a 0.5 s voltage step from -50 to +80 mV (which evokes a BKCa current), followed by a 2 s voltage ramp from +80 to -80 mV. ATPe was added at voltage values below 0 mV, where the impulse force is favorable to produce an inward cationic current through P2X channels. Immediately after 100 μM ATPe addition we observed a significant increase in BKCa current and a significant left shift of the ramp evoked current(n=6, $p<0.05$, paired Student's t test). To exclude a direct activation of BKCa channel by ATP, we worked in cell attached patch clamp configuration, where the membrane being under recording it is not in contact with ATPe and cell integrity is maintained. We observed BKCa channel activation, translated as a significant higher open probability value (NPo), after application of 100uM ATPe (control NPo: 0.0197 ± 0.0128; after ATPeNPo: 0.0552 ± 0.0239 at 0 mV, n=6, $p<0.05$, paired Student's t test).

We also tested100 μM ATPe in a Ca2+ free extracellular solution observing no effect on BKCa channel activity, which suggests that Ca2+ influx through P2X receptors is essential to activate the K+ channel.

These results show that extracellular ATP could play an important role as a regulatory mechanism of the vascular resistance involving BKCa channel as a new functional partner.

PERICARDIAL RECONSTRUCTION USING EXTRACELLULAR MATRIX BIOLOGICAL SCAFFOLDS IN A PRECLINICAL PORCINE MODEL.

NATALIA AMIGO (1), JUAN MARTÍN RIGANTI (2), CECILIA ZUBIETA (2), FRANCO CIOTOLA (2), MAURICIO RAMÍREZ (2), ARIEL PASCANER (1), DAMIÁN CRAIEM (1,2), ALEJANDRO NIEPONICE (1,2)

Closing the pericardium after cardiac surgery is recommended to prevent postoperative adhesions to the sternum. However, it is frequently not possible. Synthetic materials have been used as substitutes, with limited results due to impaired remodeling and fibrotic tissue formation. Extracellular matrix (ECM) scaffolds, recruit and facilitate the incorporation of native cells to promote constructive remodeling that resemble more the native tissue.

Aims: Evaluate the host response to ECM scaffolds in pericardium defects closure after cardiac surgery, with focus in magnitude, strength and quality of adhesions and epicardial retraction.

10 Landrace pigs were subjected to median sternotomy and a 5x7cm pericardial defect was created. The test group (n=6) was subjected to ECM repair with an 8layer device of 5x7cm. Animals in control group (n=4) were left with an open defect. Animals were euthanized at 8 weeks. Endpoints included cardiac function (Doppler ultrasound), gross morphology with adhesion assessment, mechanical testing and histology.

Softer adhesions were found in ECM group, but strong adhesions and injury of the coronary bed were found in control group. The load at failure showed no differences between the ECM and native pericardium (199.9±59,2g vs. 405.3± 99.89g P=0.0536), but tissue was weaker than native pericardium (44.23±15.01g/mm vs. 146.5±24.38g/mm P<0.01).In ECM pigs, histology resembled that of native pericardium. Control pigs showed fibrotic tissue with mononuclear infiltrate and no organized collagen fibers. Both groups had normal results without cardiac motility disorders.

In conclusion, ECM may contribute to enhance pericardial repair with tissue characteristics that may protect against the formation of postoperative retrosternal adhesions, whereas cardiac function is not affected by the implant.

SAFE – ORAL PRESENTATION AWARD

MODULATORY EFFECT OF NATIVE AND NATURALIZED PLANT EXTRACTS ON P-GLYCOPROTEIN MULTIDRUG TRANSPORTER IN CHRONIC MYELOGENOUS LEUKEMIA CELLS.

JERÓNIMO LAIOLO, MARÍA LAURA GONZÁLEZ, MARIANA BELÉN JORAY, SARA MARÍA PALACIOS, MARÍA CECILIA CARPINELLA

Instituto de Investigaciones en Recursos Naturales y Sustentabilidad José Sánchez Labrador S.J. (IRNASUS-CONICET), Córdoba, Argentina

P-Glycoprotein (P-gp) is a unique ATP-dependent transmembrane efflux pump that plays a significant role in the intracellular decreasing of anticancer drugs. Over-expression of this protein leads to the development of multidrug resistance (MDR) and constitutes nowadays one of the main obstacles to successful chemotherapy. Natural product constituents are diverse and they have potential to offer novel chemical scaffolds and leads. With the aim of finding new novel P-gp modulators, one hundred and twenty native and naturalized plants collected from central region of Argentina were screened over K562 human myelogenous leukemia cell line and its MDR counterpart Lucena 1.

Ethanolic extracts dissolved in DMSO at 100 and 50 mg/ml were assayed for their cytotoxicity activity by MTT. Intracellular doxorubicin accumulation was determined, at non-cytotoxic concentration of each extract, using high throughput flow cytometry. Fluorescence intensity radio (FIR) was calculated as the ratio between the fluorescence intensity of each cell line treated and the fluorescence intensity of its respective DMSO control.

Nineteen extracts exhibited significant P-gp modulating effects (**p*-values ≤ 0.05) at 100 mg/ml, being the most relevant: *Ligaria cuneifólia* (FIR: 1,75±0,10*); *Jarava ichu* (FIR: 1,70±0,24*); *Senecio viravira* (FIR: 1,70±0,30*); *Melinis repens* (FIR: 1,62±0,22*); *Senecio madagascariensis* (FIR: 1,62±0,17*). On the other hand, *Aloysia gratissima* (FIR: 1,30±0,10*) and *Eupatorium viscidum* (FIR:

1,23±0,06*) were effective at 50 mg/ml.
The minimum inhibitory concentration of the extracts tested will be presented.
According to the results obtained, these plants could be source of compounds capable to reverse the MDR phenotype and sensitize the leukemia cells to conventional chemotherapy.

NMDA RECEPTOR ANTAGONIST KETAMINE INDUCES A REGULATORY MACROPHAGE PROGRAM ON HUMAN MONOCYTES

WANDA NOWAK(1), IVANA G ESTECHO(1), FEDERICO M DARAY(1), EUGENIO A CARRERA SILVA(2) ANDREA E ERRASTI(1)

(1)Instituto de Farmacología, Facultad de Medicina, UBA, (2) Instituto de Medicina Experimental, ANM-CONICET, Buenos Aires, Argentina.

Background: Ketamine, a NMDA antagonist, is still used as an anesthetic but recently is emerging as a fast and potent antidepressive drug. The biology of this effect is poorly understood but new research implicates that one of the main target of its action is the immune response. This associates with the concept that inflammation contributes to the physiopathology of depression.
Macrophages are key players in the balance of pro and antiinflammatory response; therefore, the aim of this study was to elucidate the effect of ketamine, type of receptor involved and gene program elicited on human macrophages during differentiation and polarization. **Methods:** Blood samples were drawn from healthy volunteers and mononuclear cells were isolated from the cellular fraction by Ficoll gradient. After CD14 positive selection, monocytes were cultured for 7 days and treated with ketamine at different time points (day 1 or 5). LPS+INFγ, IL-4 or dexamethasone were used as positive controls of macrophage polarization. To measure the inflammatory response, LPS was added ON in some experiments at day 6. Phenotype characterization was performed by FACS analysis and gene expression by qPCR. **Results**: We found that ketamine (0.1, 1 and 10 μM) induced an antiinflammatory profile on macrophages with high expression of CD163 and MERTK, intermediate levels of CD64 and no expression of CD206, compatible with a regulatory M2c-like phenotype. mRNA levels of TGM2 and CCL22 genes, related to a M2 profile, were also up-regulated in ketamine treated macrophages. Moreover, ketamine dampens macrophage activation, with lower expression of CD80 and HLADR and diminishes TNF-α production induced by LPS. Addition of MK801, a glutamate receptor antagonist, showed that the effect is mediated by NMDA receptors. **Conclusions:** These results show that ketamine not only dampens acute inflammation but also induces an antiinflammatory program on human monocytes skewing macrophages to a regulatory M2c-like profile.

TOXOPLASMOSIS DRUGS REPURPOSED FOR CHAGAS DISEASE: IN VITRO AND IN VIVO EVALUATION OF REFERENCE DRUGS.

ERNESTO GULIN,DANIELA MARISA ROCCO, FACUNDO GARCÍA-BOURNISSEN

Hospital de Niños "Dr Ricardo Gutiérrez", Buenos Aires, Argentina

Chagas disease is endemic in Latin America and a global burden due to migration. Benznidazole (BZ) and nifurtimox (NFX) are the only drugs available for treatment but are not exempt of severe adverse events. Thus, better drugs for Chagas disease are needed. Drug repositioning is a cost-effective strategy to identify active compounds that may move forward to clinical use. Taking advantage of phylogenetic similarities and common metabolic pathways between *Toxoplasma gondii* and *Trypanosoma cruzi*, drugs currently used for Toxoplasmosis were sequentially assessed for anti-*T. cruzi* activity in *in vitro* and *in vivo* models. Azithromycin, sulfadiazine, sulfamethoxazole, pyrimethamine (PYR), atovaquone (ATV) and paromomycin were initially evaluated *in vitro* by establishing the percentage of relative activity (%RA) compared to BZ and NFX on amastigote and trypomastigote stages at a fixed concentration (10 µM for each drug). PYR and ATV showed more than 98 %RA compared to NFX on amastigotes. Hence, these drugs were further evaluated to obtain the inhibitory concentration 50% (IC_{50}) on amastigotes, and citotoxicity on Vero cells. IC_{50} values were 0.47 µM for PYR and 6.92 µM for ATV; citotoxicity was not significant. Due PYR well-known favorable human pharmacokinetics and safety properties, there was rationale enough to continue its evaluation in a murine model of acute infection. Female 5 week old BALB/c mice were infected and, at onset of patent parasitaemia, treated with PYR 50 mg/kg for 20 consecutive days. Non-treated (NT) and BZ- or NFX-treated groups (100 mg/kg/day) were included as controls. PYR did not show a significant effect on parasitaemia levels or mortality (100%) compared to NT group at the end of the study. In this screening model, PYR was the most potent drug *in vitro* but this could not be demonstrated *in vivo*.

Further studies will be conducted studying ATV as monotherapy and combined with BZ or NFX.

THERAPEUTIC EFFICACY AND BIOCOMPATIBILITY OF TRIAMCINOLONE ACETONIDE-LOADED LIPID NANOCAPSULES

MARÍA LINA FORMICA(1); GABRIELA VERÓNICA ULLIO GAMBOA(1); JEAN-PIERRE BENOIT(2), DANIEL ALBERTO ALLEMANDI(1), SANTIAGO DANIEL PALMA (1)

Triamcinolone acetonide (TA) is a synthetic corticosteroid used to treat a broad spectrum of ocular diseases. The development of TA dosage forms is limited due to its poor solubility in physiologically acceptable solvents. The aim of this work was to evaluate therapeutic efficacy *in-vitro* of novel "solvent free" TA-loaded lipid nanocapsules (LNC).

An optimized phase inversion temperature method was used to obtain TA-loaded LNC with oleic acid or glyceryl triacetate into lipid matrix. The average particle size (APS), polydispersity index (PI) and loading capacity (LC) of LNC were measured. Cell viability of human corneal epithelial (HCE) cells after TA-loaded LNC exposure was evaluated using MTT assay. In addition, the secretion of the inflammatory cytokine IL-6 by HCE cells in response to tumor necrosis factor (TNF)-α exposure (inflamed cells) was measured after treatment with TA-loaded LNC. Inflamed cells were exposed to TA-loaded LNC for a 1h and IL-6 secreted into the culture medium was measured by ELISA.

Obtained TA-loaded LNC showed acceptable APS, PI and LC. Results of biocompatibility assay did not show any significant cytotoxic effect (cell viability>70%) of TA-loaded LNC in HCE cells over studied period.

Experimental findings exhibited efficacy of TA-loaded LNC to reduce cell inflammation. IL-6 levels secreted by TNF-α inflamed cells were upper compared to those basally secreted by non-inflamed cells($p \leq 0,05$). Exposition of inflamed cells to TA-loaded LNC (1μg/ml) for the 1h, significantly reduced IL-6 production compared to control inflamed untreated cells($p \leq 0,05$). Empty LNC increase the cell inflammation significantly($p \leq 0,005$) while that TA trademark suspension showed a significant IL-6 secretion decrease($p \leq 0,05$) in comparison to both controls: non-inflamed and inflamed untreated cells.

This strategy allowed the decrease of IL-6 level of HCE cells and it could be a potential alternative to treat several ocular diseases with less adverse effects.

INDIVIDUALIZED ANTIRETROVIRAL THERAPY. IMPACT OF PHARMACOGENETIC AND THERAPEUTIC DRUG MONITORING IN THE SAFETY AND EFFICACY OF FIRST LINE ANTIRRETROVIRAL THERAPY IN PATIENTS WITH HIV INFECTION. PRELIMINARY REPORT

Up to 20% of patients discontinue first-line antiretroviral therapy at currently standard doses. We explored the utility of prior pharmacogenetic (PG) analysis and ongoing drug monitoring (TDM) to individualize the dose of efavirenz or atazanavir in naïve HIV patients.

A multiplex approach was developed including main polymorphisms of *CYP2B6, CYP2A6, CYP3A4* y *ABCB1* for efavirenz; and *UGT1A1, ABCB1 and CYP3A4* for atazanavir. Drug plasma levels were analyzed with UPLC. Median turnaround time was 22 days.

First 40 patients included in the protocol -coming from 4 clinical sites in Buenos Aires- were randomized to standard of care –SC-(25 patients) or pharmacological adaptation –PA: PG + TDM- (15 patients).

One patient in the pharmacological adaptation arm received decreased individualized doses atazanavir with proper tolerance and maintaining treatment efficacy, in 69 patient/months of follow up.

Two patients from SC arm had adverse events, and both of them had to discontinue therapy.

Pharmacological adaptation of initial and ongoing doses of first line antiretrovirals appears feasible and useful for the individualized therapeutic approach of patients with HIV infection starting treatment.

PRECLINICAL PHARMACOKINETIC OF BENZNIDAZOLE-LOADED INTERPOLYELECTROLYTE COMPLEXES FOR IMPROVED TREATMENT OF CHAGAS DISEASE

MÓNICA CRISTINA GARCÍA(1), LAURA GUZMÁN(1), PILAR ZARAZAGA(2), NICOLÁS LITERIO (2), EUGENIA OLIVERA(1), ALVARO JIMENEZ-KAIRUZ (1)(3)

Chagas disease, caused by *Trypanosoma cruzi*, is an important public health problem in Latin America and worldwide. Benznidazole (BZ) is the selected drug for its treatment. However, it shows very low solubility, several side effects and toxicity, which compromise the efficacy and safety. Moreover, the available pharmaceutical dosage forms are immediate release tablets and the treatment is administered 2 or 3 times daily for 60 days. The high frequency of administrations and long-term treatment are issues that contribute to the abandonment of therapy, affecting therapeutic success. In a previous work, we have developed BZ-loaded interpolyelectrolyte complexes (IPEC) based on polymethacrylates (EE-EL-BZ) and polysaccharides (Ch-AA-BZ) that showed controlled release of BZ. These systems would reduce the adverse effects of BZ and/or allow reducing its frequency of administration. Therefore, this work aimed to evaluate the preclinical pharmacokinetics of BZ-loaded IPECs compared to the currently available tablets (Abarax). The studies were performed six healthy adult mixed breed dogs, with a 3×2 cross-over design. Each dog received all orally administrated treatments after three experiments, with a washout period of 15 days. They received 100 mg of BZ by single oral dose of EE-EL-BZ, Ch-AA-BZ or Abarax, with a randomization schedule. BZ quantification was performed in plasma by high performance liquid chromatography validated method. The AUC of BZ-loaded IPECs was higher than reference treatment ($p<0.01$). The C_{max} of Ch-AA-BZ and t_{max} of both IPECs were higher than Abarax ($p<0.05$). The k_a, $t_{1/2}$ and MRT were similar for all the treatments evaluated. Our results indicate that bioavailability of BZ was adequate in the administration of both IPECs. The pharmacokinetic parameters demonstrated that the BZ-loaded IPECs prolonged drug release and provided an increase in the maintenance of drug concentration *in vivo*, which would allow reducing

(1049) **β-LAP HALOGENATED-DERIVATIVE PFB AS A PROMISING NQO1-DEPENDENT ANTICANCER CHEMOTHERAPEUTIC AGAINST MELANOMA**

María Julia Lamberti (1), Marianella Chiaramello (1), Luis Exequiel Ibarra (1), Nadia Soledad Ualdegaray (1), Ana Belén Morales Vasconsuelos (1), Sabrina Ferreira (2), Natalia Belén Rumie Vittar (1), Viviana Alicia Rivarola (1)
(1) Universidad Nacional de Río Cuarto, (2) Universidad Federal de Río de Janeiro

The elevated expression of the NQO1 in many human solid tumors along with its ability to activate quinone-based anticancer agents, such as the natural product β-Lapachone (β-Lap), makes it an excellent target for enzyme-directed drug development. NQO1 plays an important role in the initiation stage of melanoma and its correlation with poor patient outcome make it an intriguing target. The most dangerous aspect of melanoma relay on the metastatic ability in later stages. Therefore, new effective and safe therapeutic agents for metastatic melanoma are needed. In this study, metastasis-derived human melanoma cell lines exhibited higher resistance to β-Lap (LD50 SkMel-2 and 1205Lu: not reached) compared to primary-site derived melanoma cells (LD50 SkMel-28: 1.48 μM) ($p<0.05$). The cytotoxic effect of β-Lap was reversed with coadministration of dicumarol, a specific inhibitor of NQO1. NQO1 inhibition preferentially prevented cell death of non-metastasis-derived human melanoma (94.5% of reversion; $p<0.001$). Interestingly, dicumarol had no effect as an antagonist of β-Lap in the murine melanoma cell line B16, but stable overexpression of NQO1 completely restored chemosensitivity ($p<0.001$). These results are in agreement with earlier studies suggesting that β-Lap-induced cytotoxicity might involve differential NQO1 status required for its bioactivation. In a previous report, we proposed halogenated β-Lap derivative PFB as an excellent NQO1 substrate and anticancer agent. Here, PFB had considerable higher potential chemotherapeutic activity than β-Lap on SkMel-2 (LD50 β-Lap: 3.50 μM; LD50 PFB: 2.89 μM; $p<0.05$). These data suggest that PFB possess properties that make it more attractive than the parent β-Lap for treating metastatic-derived melanoma cells. Our preliminary results support the necessity of design new strategies to induce NQO1 activity in cancer cells as a promising approach for bioreductive anticancer drugs.

(724) **A *N*^{4}-ARYL SUBSTITUTED THIOSEMICARBAZONE DOWN-MODULATES METASTASIS-RELATED PROPERTIES OF TRIPLE NEGATIVE 4T1 MOUSE MAMMARY CANCER CELLS**

Aldana Sólimo (1), María Cristina Soraires Santacruz (2), Andrea Loaiza Perez (1), Elisa Bal de Kier Joffé (1), Liliana Finkielstein (2), Mariana A Callero (1)
(1) Instituto De Oncología Ángel H. Roffo. (2) Universidad De Buenos Aires, Facultad De Farmacia Y Bioquímica, Departamento De Farmacología, Cátedra De Química Medicinal.

Triple negative breast cancer (TNBC) is defined by a lack of expression of estrogen (ER) and progesterone (PgR) receptors as well as HER2/neu. This pathology represents about 15% of all types of breast cancer and among all subtypes TNBC is associated with a worse prognosis and a higher incidence of visceral metastasis. The lack of targeted therapies and the poor prognosis of TNBC patients have fostered a major effort to develop new alternative treatments. Thiosemicarbazones are synthetic compounds that exhibit several pharmacological activities. Previously, we found that T_2, a *N*^{4}-aryl substituted thiosemicarbazone, had cytotoxic activity on 4T1 mouse mammary tumor cells. Now, we have investigated the action of T_2 on metastasis-related properties of 4T1 cells.

First, we found that T_2 significantly diminished 4T1 clonogenic capacity in a dose-dependent manner (T_2 2.5 mM= 58.8%; T_2 5 mM= 33.3% and T_2 10 mM=0.014% vs control cells). We also observed that 4T1 migratory capacity was down-regulated by T_2 (T_2 2.5 mM= 61.8 ± 2%; T_2 5 mM= 25.4 ± 4% and T_2 10 mM=19.6±2% respect to control cells, pÂ0.05). In order to evaluate T_2 action on cancer stem cells sub-population, we quantified Lin-/CD24+/CD29^h cells by cytometry and found that T_2 reduced this population (T_2 2.5 mM= 54.4 ± 2%; T_2 5 mM= 29.8 ± 14.6% and T_2 10 mM=27.9±14.6% vs control cells, pÂ0.05). This effect was in accordance with a significantly lower mammosphere-forming capacity shown by 4T1 cells after T_2 treatment ($p<0.05$). Finally, we evaluated pluripotential genes expression by real time qPCR and found that T_2 induced a significant down-regulation of Nanog, Oct-4 and Sox-2 expression ($p<0.05$).

In conclusion, our results show that T_2 inhibits some of the metastasis-related properties of 4T1 cells, placing this compound as a candidate for in vivo experiments to investigate its anti-metastasic potential against TNBC.

(1112) **ANTIMETASTATIC EFFECT OF THE PENICILLIN DERIVATIVE TAP6 IN MELANOMA CELLS**

Elizabeth Barrionuevo (1), Patricia G. Cornier (2), Carina M. L. Delpiccolo (2), Dora B. Boggián (2), Ernesto G. Mata (2), Leonor P. Roguin (1), Viviana Blank (1)
(1) Instituto de Química y Fisicoquímica Biológicas, Departamento de Química Biológica, Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, (2) Instituto de Química Rosario, Facultad de Ciencias Bioquímicas y Farmacéuticas, Universidad Nacional de Rosario, (3)

Abstract: Metastatic dissemination of cancer cells is the main cause of death in melanoma patients. In the search of new antimetastatic compounds, in a previous work, we found that the penicillin derivative named TAP6, formed by a penicillin linked to the dipeptide Phe-Leu through a triazole group, inhibited adhesion and migration of B16F10 metastatic murine melanoma cells. In order to continue studying the antimetastatic properties of TAP6, we investigated the effect of the penicillin derivative on B16F10 cells invasion. Transwell invasion assay results demonstrated that a 10 μM concentration of TAP6 inhibited cell invasion after 18 h treatment (96.1±0.4%, $p<0.001$). Gelatin zymography of supernatants collected after incubating B16F10 cells for 24 h in the presence of 10 μM TAP6 showed a reduction in matrix metalloproteinase (MMP)-2 and -9 proteinase activity of 33±4% and 43±5%, respectively. Additionally, under the same incubation conditions, we observed a significant decrease in the expression levels of MMP-2 (48.2±9.8%, $p<0.001$) and MMP-9 (81.7±6.8% $p<0.001$) by Western blot assay. Wnt/β-catenin signalling pathway is activated in various cancers and promotes metastatic spread by increasing invasion, however, it has controversial roles in the metastatic spread of melanoma. By Western blot analysis, we found that a 10 μM concentration of TAP6 inhibited 92.5±2.8% the expression of β-catenin after 18 h of treatment. Under these conditions, we have also observed a reduction in the cytosolic levels of β-catenin by immunofluorescence microscopy. In conclusion, we demonstrated that TAP6 exhibits antimetastatic properties through the inhibition of cell invasion and MMP-2 and 9 expression and activity. Furthermore, we found that TAP6 significantly inhibited β-catenin expression. These findings encourage us to continue studying this penicillin derivative as a potential candidate for the treatment of melanoma.

metalloproteinases

(681) **ANTITUMORAL IN VIVO EFFECT OF MICROSPHERES FOR CHEMOEMBOLIZATION**

Clara Sanchez Terrero (1), Jorge Cardoso (1), Silvia I. Vanzulli (1), Lucas L. Colombo (2), Edisón Rivera (3), Luisa Ambrosio (3), Luciano Parodi (4), Andrés Vidal (4), Gisela Ruthy Solá (1), Miguel Prado (3), A. Cristina Zarlenga (1)
(1) Centro Oncológico de Medicina Nuclear del Instituto Ángel H. Roffo (UBA-CNEA). (2) Área Investigaciones del Instituto Ángel H. Roffo (UBA). (3) División de Aplicaciones Médicas e Industriales del Centro Atómico Bariloche-CAB (CNEA). (4) Bioterio del Centro Atómico Ezeiza-CAE (CNEA).

Introduction: The Bariloche Atomic Centre (CAB-CNEA) develops Porous silica Microspheres (PME) as a drug carrier matrix. Our purpose is to evaluate the in vivo effect of Doxorubicin loaded PME (D-PME) on: (I) development and (II) growth of DHD/K12 rat colonic adenocarcinoma.

Materials and Methods: 600mg of 25-45um diameter PMEs were loaded by shaking for 24 hours in Doxorubicin Hydrochloride solution (Doxo, 2mg/ml) or saline (empty PME, Controls).

Two groups of BDIX rats were inoculated subcutaneously with 10^6 DHD/K12 tumor cells (TC) for two different experiments (Exp): Exp (I) TCs were inoculated mixed with D-PME (n=13) or mixed with empty PME (n=14). Exp (II) established tumors (60-80mm^3) were injected intra-tumor: with empty PME (n=14) or with D-PME (n=16).

In both Exp, animals were sacrificed thirteen days after treatment. Tumors were measured and processed for histopathology.

Results: Tumors volume at sacrifice were: Exp (I) Control (with empty PME): 60.99±34.66mm^3 vs Experimental (D-PME): 1.72±1.57mm^3 ($p < 0,0001$). Exp (II): Control (empty PME): 139,81±100,16mm^3 vs. Experimental (D-PME): 35,41± 19,13 mm^3 ($p < 0,0001$).

Histologically, in both experiments, tumors treated with D-PME showed more necrotic areas than those treated with empty PME (Controls). Only Exp II with D-PME showed damaged epidermis.

Conclusion: We demonstrate that the PMEs developed by CAB-CNEA, load and release Doxo enough to produce an antitumor effect on both development and growth of experimental DHD/K12 rat colonic adenocarcinoma.

(818) **CLOZAPINE AS A POTENTIAL ANTI-CANCER DRUG**

Melisa Nicoud (1), Helena Sterle (1), Noelia Massari (2), Mónica Táquez Delgado (1), Diego Martinel Lamas (1), Verónica Herrero Ducloux (2), Graciela Cremaschi (1), Vanina Medina (1)
(1) Instituto de Investigaciones Biomédicas (BIOMED, UCA-CONICET), Buenos Aires, Argentina, (2) Facultad de Ciencias Naturales y de la Salud, Universidad Nacional de la Patagonia San Juan Bosco, Chubut, Argentina.

We have previously demonstrated that clozapine, a well-known antipsychotic inhibited proliferation of human breast cancer and melanoma cells. The aim of this work was to investigate the effect of clozapine alone or in combination with a widely used chemotherapeutic agent (doxorubicin, Dox), on an immunocompetent triple negative breast cancer (TNBC) model. For that purpose, proliferation and apoptotic assays and DNA damage markers were studied in murine 4T1 TNBC cells. *In vivo* studies were performed in syngeneic mice, inoculated orthotopically with 4T1 murine TNBC cells. Results indicate that clozapine reduced proliferation in a concentration dependent manner. At 10 μM concentration it produced a 2.5-fold decrease in clonogenic proliferation and in BrdU incorporation of 4T1 cells ($P<0.01$). This effect was associated with an induction of apoptosis, evidenced by an increased Annexin-V staining, an increase in the differentiation marker Nile red, and enhanced ROS levels, all assays evaluated by flow cytometry. Accordingly, *in vivo* treatment of 4T1 tumors with clozapine (1 mg/kg.day, *sc*) reduced tumor weight (1.3±0.1 vs. 2.1±0.3 g, $P<0.05$). Histopathological analysis indicate that clozapine-treated tumors show extended areas of differentiation and reduced mitotic index. Combined treatment of clozapine and doxorubicin was more effective in reducing growth *in vitro* and *in vivo* than single treatments. Clozapine potentiated doxorubicin-induced apoptosis and proliferation reduction ($P<0.01$). We conclude that clozapine could be an effective drug for the treatment of TNBC. Prospective clinical trials are warranted to confirm the clinical efficacy of this currently used drug for breast cancer therapy.

Keywords: clozapine, breast cancer, apoptosis, combined therapy

(1230) **OCT-4 EXPRESSION WAS INCREASED IN RESISTANT CANCER STEM CELL-LIKE SUBPOPULATION IN COLORECTAL CANCER**

Julia Milena Gallino Fernández, Rodrigo Lloyd, Milena Batalla, Maria Belén Cerda, Florencia Giannoni, Alvaro Conde, Lucia Policastro

Radiochemoresistance of tumors has been associated with the presence of a small subpopulation of tumor cells called cancer stem cells (CSCs). These cells had been shown not only linked with high resistance to chemotherapeutic drugs but also are associated with metastatic recurrences. Embryonic markers such as Oct-4, Nanog, Sox-2 are associated with resistance to chemotherapeutic drugs in some cancer. However, little has been reported about the expression of these embryonic markers in colorectal (CRC) CSCs subpopulation. The aim of this work is the study of the mentioned embryonic marker in sensible and oxaliplatin-resistant (OXA) human CRC cancer lines, and in cultures derived of them enriched with CSC-like subpopulation, in order to detect novel markers associated to resistance in these cells. We characterized the expression of Oct-4, Nanog and Sox-2 by immunofluorescence, cell cytometer and real time-PCR in sensible or resistant human CRC cell to oxaliplatin (T-84 and HCT-116) and in cultures enriched by CSC-like subpopulation. The last cultures were obtained by growing tumor cells as colonospheres (CSPHE) in minimum medium in low adherence surfaces. On the other hand, we also measured the reactive oxygen species (ROS) levels as a characteristic associated to CSC-like subpopulation. The expression of Nanog and Sox-2 was not changed in sensible and resistant cell lines grown in monolayer or as CSPH cultures. However, the expression of Oct-4 was positive in 6-12% and 40-50% of sensible cells that were grown in monolayer or as CSPHE respectively. About chemoresistant cells lines, 40-60% and 75-85% of cells were positively for Oct-4 depending if cells were grown as monolayer or as CSPHE respectively. About ROS level, cells that were grown as CSPHE had shown significant lower levels in respect to cells that were grown as monolayer. These results showed that Oct-4 could be a promising marker to identify chemoresistant cells with CSC-like characteristics in CRC.

Abstract: Tumor stroma is one of the emerging topics of interest in cancer research. In the present work, we evaluated the effects of Conditioned Media (CMs) of human adipose tissue explants from normal (hRAN) and tumor (hRAT) kidney on proliferation of tumor (786-O, ACHN) and non tumor (NK-2) renal epithelial cells. We also evaluated: 1) leptin, adiponectin and versican mRNA expression in hRAN and hRAT; 2) adiponectin, ADAMTS1 and perilipin expression in hRAN- and hRAT-CMs; and 3) adiponectin and perilipin expression in hRAN- and hRAT.

Human renal adipose tissues were obtained from patients with re-

nal cell carcinoma (hRAT, n=6) and kidney donors (hRAN, n=8). The CMs from hRAN and hRAT were collected after 24h of incubation. 786-O, ACHN and NK-2 cells were grown and incubated with CMs for 24 and 48h. Proliferation was quantified by MTT; mRNA expression was evaluated by real-time PCR, protein expression by WB and immunohistochemistry. Statistical differences between experimental conditions were evaluated by one-way ANOVA or t test. Tukey´s post hoc tests were performed.

We found a higher RNA expression of leptin (a major adipokine with tumorigenic effects) and versican (a proteoglycan that is essential in epithelial-stromal interaction and intracellular signaling) in hRAT *vs.* hRAN explants (p<0.01). Also, we observed that adiponectin (a major adipokine with anti-tumorigenic effects), and perilipin expression were significantly increased in hRAN *vs.* hRAT explants (p<0.05) and in addition we observed a lower protein expression of perilipin (marker for mature differentiated adipocyte) in hRAT-CMs *vs.* hRAN-CMs (p<0.05). Added to this, hRAN-CMs significantly increased the proliferation of 786-O and HK-2 compared to control- and hRAT-CMs after 24h (p<0.05).

In conclusion, the changes observed in the adipose microenvironment could be favoring tumor progression and therefore, the tumor stroma should be taken into consideration when dealing with a malignancy.

Keywords: human adipose tissue, renal epithelial cells, cancer, epithelial-stromal interactions.

(830) **TISSUE CULTURES FROM PATIENT DERIVED XENOGRAFTS (PDX): A NEW FAST METHOD TO TEST THE EFFECT OF THERAPEUTIC AGENTS.**

Gabriela Pataccini (1), Silvia Vanzulli (2), Marcos Liguori (3), Paola Rojas (1), Andrés Elia (1), Paula Martínez (3), Javier Burruchaga (3), Pedro Gonzalez (3), Hugo Gass (3), Claudia Lanari (1), Gonzalo Sequeira (1)
(1) IBYME-Instituto de Biología y Medicina Experimental, (2) Academia Nacional de Medicina de Buenos Aires, (3) Hospital de Agudos Magdalena V de Martínez.

Precision medicine needs to be accompanied by diagnostic tools to determine which patient may benefit from therapeutic agents. For this purpose, to test drug efficacy, patient derived xenografts (PDX) or *ex vivo* assays are currently being developed. We have recently shown a 32% of success evaluating the effects of antiprogestins in tissue cultures (BCTC). However, with this technique few treatments can be simultaneously tested due to the small size of breast cancer samples. The main aim of this study is to develop PDX from luminal breast cancers and evaluate if BCTC from these PDX reproduce the observed drug effects. In this study, we evaluated the effect of doxorubicin (Dox; 1 μM) and/or paclitaxel (Pax; 50 nM) on 16 BCTC. In addition, 20 PDX were attempted inoculating breast cancer cells into NSG female mice treated or not with estrogen pellets (0.5 mg). The study was approved by institutional review boards. In the BCTC exposed to chemotherapeutic agents we observed histological and cytological changes related to Dox or Pax exposure such as macronuclei, necrotic foci and apoptosis. Most of the PDX developed small tumors and remained quiescent. PDX-485 started to grow similarly in E2-treated or untreated mice. Tumor 485 was a tumor relapse (luminal B; ER: 40%, PR: 30%, Ki-67 90%, HER2: negative). Dox inhibited tumor growth (p<0.05), and histological features of Pax effects were registered although no significant difference was observed in tumor size as compared with control group. Mifepristone (MFP), an antiprogestin, did not exert any effect. Sensitivity to Dox, Pax and MFP was evaluated in PDX-485 tissue cultures. Dox proved to be the most effective drug (p<0.05) inducing a decrease of Ki-67 expression and an increase in Casp-3, both evaluated by immunohistochemistry (p<0.05). We conclude that BCTC derived from PDX represent a promising tool that may be used for drug testing or to increase the number of drug combinations to be tested in short periods of time.

Keywords: breast cancer, patient derived xenografts, therapeutic agents

(1594) **CHLORPYRIFOS PROMOTES CELL INVASIVENESS AND ACTIVATES P-38/GSK3B PATHWAY MEDIATED BY ROS INCREMENT IN BREAST CANCER CELL LINES.**

Chlorpyrifos (CPF) is one of the most common pesticide used for control pest in agriculture in our country. Previously, we reported that 0.05 uM CPF induced cell proliferation in an estrogen receptor dependent way in MCF-7 cells and 50 uM CPF inhibited cell proliferation via p-ERK induced by an increment of reactive oxygen species (ROS) in MCF-7 and MDA-MB231 cells. Objective: Our aim was to analyze if CPF may promote cell invasion and the associated signaling in breast cancer cell lines. Methods: MCF-7 and MDA-MB231 cells were exposed or not to CPF (0.05 or 50 uM). Cell invasiveness was examined by the Matrigel® invasion assay and c-SRC, p38 and GSK3β phosphorylations by Western Blot. Results: 50 uM CPF induced the invasion in MDA-MB231 after 24 h, (60% over control, p < 0.01) and MCF-7 cells after 48 h (400% over de control, p< 0.001). CPF at 0.05 and 50 uM increased c-SRC phosphorylation (p-cSRC) after 60 min in MCF-7 cells (19% and 14% over control respectively, p< 0.05) and this effect was reverted by catalase (30 IU/mL). In MCF-7 cells, 50 uM CPF enhanced phospho-p38 (p-p38) after 30 minutes of exposure (27% over control, p<0.05) and both, CPF 0.5 (145% over control, p <0.01) and 50 uM (70% over control, p< 0.01), incremented p-p38 after 1 h. In MDA-MB231, 50 uM CPF induced p-p38 after 1h of exposure (34% over control, p<0.05). In both, MCF-7 and MDA-MB231 cells, 50 uM CPF action on p38 was reversed by adding catalase (30 IU/mL). In MCF-7 cells, CPF 0.05 uM induced phospho-GSK3β (p-GSK3β) after 5, 30 and 60 min (67%, p<0.01; 75%, p<0.05%; 55%, p<0.05 over control respectively); CPF 50 uM induced p-GSK3β after 5 min (26% over control, p<0.05) and could be reverted by catalase (30 IU/mL). In MDA-MB231, p-GSK3β was also induced by CPF 50 uM (p< 0.05). Conclusions: All together, our results indicate that CPF 50 uM induces cell invasion in MCF-7 and MDA-MB231 attended with c-SRC phosphorylation and/or the activation of p-38/GSK3β pathway mediated by ROS.

(031) **CIRCADIAN CONTROL OF LIPID AND REDOX METABOLISMS IN PROLIFERATIVE GLIOBLASTOMA CANCER CELLS**

Paula Micaela Wagner, Lucas Sosa-Alderete, Lucas Gorné, Mario Eduardo Guido
CIQUIBIC-CONICET; Dept. Biol Chem Ranwel Caputto. FCQ-UNC

Immortalized cell lines contain circadian clocks conducting transcriptional/translational rhythms in gene expression whereas metabolic rhythms can persist without transcription. Circadian rhythm disruption by modern life may cause higher cancer risk; however, little is known about clock functioning in tumor cells. Here we evaluated glycerophospholipid (GPL) and redox metabolisms in cultures of glioblastoma T98G cells under proliferation (P) or partial arrest (A), synchronized with dexamethasone (100 nM) (time 0) and collected at different times. In arrested cultures, mRNAs for clock- (*Bmal1, Per1, Rev-erbα)* and GPL enzyme genes, and ^{32}P-GPL labeling exhibited circadian rhythmicity; oscillations were also found in the redox state/peroxiredoxin oxidation cycles. In proliferating cells, circadian rhythms of gene expression were lost or their periodicity shortened whereas the metabolic rhythms persist with a similar or longer period to that observed under A Also, cell viability significantly changed over time after bortezomib (500 nM) treatment. Nevertheless, cell viability and redox state rhythms were altered when *Bmal1* expression was knocked down by CRISPR/Cas 9 genomic editing

technology. Results support that a metabolic clock operates in proliferative tumor cells regardless the molecular clock; property that may confer tumor susceptibility for a time-dependent chemotherapy.

Keywords: circadian rhythm, tumor cell, glioblastome, clock gene, glycerophospholipid metabolism, redox state.

(1363) **IN VITRO EFFECTS OF T_4 ON APOPTOSIS AND PROLIFERATION OF MAMMARY TUMORS**

IMBECU

Our aim was to study the genomic effects produced by thyroid hormones (TH) on mammary tumors from hypo-, eu- and hyperthyroid rats. Female Sprague Dawley rats were treated with a single dose of dimethylbenzathracene (15 mg/rat) at 55 days of age, and were divided into three groups: hypothyroidism (HypoT; 0.01% 6-N-propyl-2-thiouracil in drinking water, n=10), hyperthyroidism (Hyper, 0.25mg / kg / day Tyroxine -T_4- via sc; n=10) and EUT (untreated control, n=10). At sacrifice, tumor explants were obtained and treated with 10^{-10} M T_4 and/or 10^{-9} M 17β-estradiol (E_2) in DMEM/F12 without phenol red with 1% Charcoalized Fetal Bovine Serum (SFBc) for 24 h to evaluate changes in the expression of hormone receptors and proteins related to apoptosis and proliferation by immunohistochemistry and Western Blot. Statistical analysis was performed using ANOVA I and Bonferroni's test as post hoc. Administration of T_4, E_2 and T_4+E_2 induced a significant increase in KI67 expression in all tumors. Only T_4 stimulation decreased total and cleaved caspase 3 and PARP expression in HypoT tumors while a slight increase of both apoptotic markers was observed in the Hyper tumors. No significant apoptotic changes were observed in the tumors of EUT. Regarding hormone receptors, administration of T_4 increased cytoplasmic progesterone receptor (PgR), nuclear expression of thyroid hormone receptor β (TRβ) and favored the translocation to the nucleus of estrogen receptor (RE) β in HypoT tumors. T_4 enhanced the nuclear and cytoplasmic expression of REα and REβ in Hyper tumors. T_4 and T_4+E_2 augmented the expression of REα and PgR in EUT. E_2 did not significantly modify the expression of hormone receptors. In conclusion, the administration of T_4 induced a differential expression of hormone receptors according to the thyroid state of the tumor. It has a proliferative effect on all mammary tumors independent of the thyroid state but it only showed an antiapoptotic role in Hypot tumors.

Keywords: caspase 3, PARP, tyroxine, KI67, dimethylbenzathracene.

(1168) **PHOSPHORILATED S6 (pS6) EXPRESSION AND TUMOR LOCALIZATION IN RESPONSE TO NEOADJUVANT CHEMOTHERAPY IN BREAST CANCER**

María Cecilia Perrone (1), María Laura Polo (1), María Jimena Rodríguez (1), Marina Riggio (1), Diego Enrico (1), Marina Benes (2), María Mac Donnell (3), Ariel Zwenger (3), Virginia Novaro (1)

Neoadjuvant treatment benefits include *in vivo* assessment of tumor response to treatment as well as tumor reduction before surgery. In a recent study, we observed that neoadjuvant endocrine therapy in luminal breast cancer induced a reparative stromal reaction, including neovascularization, immune cells infiltration and carcinoma-associated fibroblasts that stain for phosphorylated S6 (pS6), a protein downstream PI3K/AKT/mTOR pathway. We also demonstrated that stromal levels of pS6 correlated with tumor shrinkage percentage after treatment ($p<0.05$). Here, we aim to analyze if pS6 expression and localization are also associated with the therapeutic response to chemotherapy in breast cancer. To accomplish this, we assembled tissue microarrays with pre and post neoadjuvant chemotherapy samples of 129 invasive luminal breast carcinomas obtained from Hospital Provincial de Neuquen, and performed immunohistochemistry for aSMA (smooth muscle actin) and pS6. We confirmed that stromal fibroblastic-like pS6+ cells are mainly aSMA+ whereas epithelial pS6 was reduced after therapy. To study the mechanisms involved in tumor response to chemotherapy, in a mouse model of luminal breast cancer we used two chemotherapic regimens: FAC (fluorouracil, adriamycin and cytoxan) and CMF (cyclophosphamide, methotrexate and fluorouracil). After 7 days of treatment, we observed high levels of apoptosis, cytostasis and necrosis that cover nearly 50% of the tumor area, together with some stromal reaction. Immunohistochemistry assessment showed a switch of pS6 stain from epithelial to stromal cells, along with higher levels of aSMA. We conclude that, as reported for endocrine therapy, chemotherapy induces S6 activation in the stroma. Our efforts are now set on trying to identify the pS6+ stromal cell population and to understand its regulation in order to evaluate its potential use as a predictive biomarker.

Key Words: breast cancer; chemotherapy; PI3K/AKT/mTOR pathway.

(514) **THYROID HORMONE MEMBRANE RECEPTOR INHIBITION IN THE TREATMENT WITH REXINOIDS OF CUTANEOUS T CELL LYMPHOMA**

Maria Mercedes Debernardi (1), Alejandra Paulazo (1), Helena Sterle (1), Maria Celeste Diaz Flaque (1), Leandro Cerchietti (2), Graciela Cremaschi (1), Maria Florencia Cayrol (1)

CTCL are exposed to a complex paracrine and endocrine environment that influence their progression from skin to visceral disease. One of the most common treatments for CTCL, the rexinoid bexarotene (Bex), is associated with hypothyroidism being patients candidate for thyroid hormone (TH) replacement therapy. We recently found that TH, mostly through the action on its membrane receptor (mTR, integrin $\alpha V\beta 3$) is required for the proliferation of T cell lymphomas (TCL), including CTCL. The consequences of TH administration on the activity of Bex in CTCL cells are unknown. Our aim was to study the effect of TH on the anti-lymphoma activity of rexinoids.

We first evaluate cell viability and apoptosis induction of human CTCL cells HuT78 and MJ and murine TCL EL4 cells treated with Bex in the presence and absence of physiological levels of TH. As expected, Bex decreased the viability and induce apoptosis on all the cell lines, but in presence of TH both effects decreased by 15-40% ($p<0.01$). These results support the notion that Bex should not be administered with TH replacement. However, beside the metabolic dysfunction, hypothyroidism could also favor tumor progression.

We thus determine if the inhibition of the mTR would be sufficient to decrease the pro-survival effect of TH on cells treated with Bex. We found that the inhibitor of the integrin $\alpha V\beta 3$, cilengitide, not only avoided the pro-survival effect of TH but increased the activity of Bex *in vitro* on HuT78, MJ and EL4 cells. We also found that the combination of both drugs results in a significant increase in the inhibition of the transcriptional expression of anti apoptotic (*BCL2, BCL2L1)* and cell cycle genes (Cyclins) and in the induction of pro apoptotic genes (*BID, BAX)* (in all the cases at least $p<0.05$ vs Bex alone).

These results will be the rationale to perform *in vivo* experiments using a murine model of EL4 LCT tumor to evaluate if this mechanism can be therapeutically capitalized to improve Bex treatment.

Buenos Aires, Argentina

Immunophilins (IMMs) are a family of proteins that bind to immunosuppressive drugs and show peptidylprolyl isomerase (PPIase) activity. FKBP51 is an Hsp90-binding cochaperone able to bind the macrolide FK506, which in turn, abolishes PPIase activity. We have previously demonstrated that FKBP51 forms complexes with the reverse transcriptase subunit of telomerase, hTERT, via de molecular chaperone Hsp90. hTERT is highly expressed in cancer cells, where it is required to compensate the loss of telomeric DNA after each successive cell division, and also shows the antiapoptotic action in tumor cells. The IMM FKBP51 also shows antiapoptotic action and is overexpressed in cancer cells. Therefore, we investigated the potential anticancer activity of the IMM ligand FK506. In vitro treatment of HeLa tumor cells with FK506 decreases cell viability, possibly due to inhibition of the PPIase activity of the IMM. Importantly, in vivo treatments with FK506 of xenographic tumors generated in Squid/Nod mice significantly decreases tumor growth. Inasmuch as FK506 shows similar affinity for both IMMs FKBP51 and its close-related partner FKBP52, we tested a new synthetic drug named SAFit1, which is a potent and selective inhibitor for FKBP51. We evaluated the possible effect of this synthetic drug compared to FK506 in tumor processes, and demonstrate that SAFit1 exhibits a significant antitumor activity. Interestingly, the molecular chaperones Hsp90 and Hsp70 relocalize in the cytoplasm of drug-treated cells generating aggregation bodies that are not classified as stress granules since they do not contain the stress granule RNA-binding protein TIAR-1. Taking together, these studies confirm the hypothesis that FKBP51 is a novel antiapoptotic factor related to tumor development.

(1698) **MCF7 CELLS OVEREXPRESSING A NOVEL HUMAN EPITHELIAL CADHERIN SPLICE VARIANT ACQUIRE A TRIPLE NEGATIVE PHENOTYPE. STUDIES *IN VITRO* AND *IN VIVO***

Marina Rosso, Lara Lapyckyj, María Laura Matos, María José Besso, María Victoria Mencucci, Mónica Hebe Vazquez-Levin
IBYME (CONICET-FIBYME)

Breast cancer (BC) is the fifth most common cancer and the leading cause of cancer death in women worldwide. Alterations in Epithelial cadherin (Ecad) expression and functions have been associated with BC progression. However, the molecular mechanisms underlying Ecad deregulation have not been fully elucidated. We have recently reported the identification of a novel human Ecad alternative splice variant (Ecadvar) that differs from the wild-type mRNA (Ecadwt) by lacking the first 34 nucleotides of exon 14. MCF7 cells stably transfected with pcDNA3-Ecadvar (MCF7-Ecadvar) showed a fibroblast-like morphology, downregulation of Ecadwt (transcript/protein) and changes in other epithelial-to-mesenchymal transition markers, reduced cell-cell adhesion and increased cell migration and invasion, when compared to MCF7-pcDNA3 (control) cells.

To further characterize the relevance of Ecadvar expression in BC progression and aggressiveness, mRNA levels of estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor 2 (HER2), three key markers of BC prognosis and treatment, were evaluated. As result, a decrease ($P<0.05$) in ER alfa, PR and HER2 mRNA levels was found in MCF7-Ecadvar compared to control cells, while no changes were observed in ER beta mRNA levels. Moreover, no detectable levels of ER alfa protein were registered in MCF7-Ecadvar cells.

Injection of MCF7-Ecadvar and MCF7-pcDNA3 cells into immunodeficient female mice receiving exogenous estradiol supplementation led to tumor generation with sustained growth over time in both cell lines. However, only MCF7-Ecadvar cells produced tumors without exogenous hormone supplementation, which were similar in size to those obtained for this cell line in mice injected with estradiol.

These findings revealed the acquisition of a triple negative phenotype in MCF7-Ecadvar cells. Alterations in Ecadvar expression levels may promote tumor progression and resistance to hormone therapy in women with BC.

Key words: cancer, breast, Epithelial Cadherin, alternative splicing, triple negative

(051) **MULTIDIMENSIONAL ANALYSIS OF IN VITRO TRIDIMENSIONAL (3D) CULTURES: COMPUTATIONAL TOOLS DEVELOPMENT FOR MICROSCOPY IMAGES**

Marina Belén Cuenca (1,2), Melina Muñoz Bernart (1), Lucía Canedo (1), Hernán Edgardo Grecco (2), Carolina Perez Castro (1)

Understanding cellular processes such as tumor progression and asymmetric division requires biological models that replicate as close as possible the conditions found in living tissue. Tridimensional (3D) cell culture technologies such as spheroids and organoids provide this model systems but create new methodological challenges to efficiently characterize their growth and internal structure. In this work, we present a modular, extendable and easy to use open source Python toolbox to obtain parameters of interest in this kind of culture. Using glioblastoma multicellular spheroids in suspension and embedded in agarose, we demonstrate a pipeline of automatic segmentation of transmission or fluorescence images, recognition of cells clusters, and morphological characterization with the possibility to apply it to tridimensional reconstructions. By making this available to the scientific community, we expect that improving the characterization of 3D cell systems provides a way to better optimize and standardize culture and assess the effect of drug in screening assays.

(1300) **OPTIMAL LACTATION EARLY IN LIFE ACTIVATES THE EXTRINSIC APOPTOTIC PATHWAY IN MAMMARY TUMORS IN ADULTHOOD**

Flavia Santiano (1), Corina Sasso (1), Leila Zyla (1), Fiorella Campo Verde-Arboccó (1), Flavia Bruna (1), Virginia Pistone-Creydt (1), Francisco López-Aguilera (2), Constanza López-Fontana (1), Rubén Carón (1)
(1) IMBECU. (2) Innovis Laboratorio Bioquímico Integral.

Studies in rodent models show that exposures to diet during the posnatal life, in periods when the mammary gland undergoes extensive modeling and re-modeling, alter susceptibility to carcinogen-induced mammary tumors. The objective of the present study was to analyze if adequate breastfeeding generates changes in the biology of mammary tumors developed in adult life. To do this we used Sprague Dawley female litters divided into 3 (L3), 8 (L8) or 12 (L12) pups per mother, and, at the age of 55 days, they were treated with a single dose of dimethylbenzanthracene (15 mg / rat) to study the latency, incidence, progression and tumor bilology. *We performed a microscopic analysis of mitosis and apoptosis to asses the effect of differential lactation on the development of the tumors. We additionally evaluated mitosis by IHC of PCNA and determined the expression of caspase 8, Bid, Bax, Bcl2 and caspase 9 by western blot from the tumors.* Incidence was expressed as percentages and compared by Fisher test. Other comparisons were performed by ANOVA I and Bonferroni's test as post hoc. *There was a lower incidence and a higher latency in L3 compared to the other groups. The mitotic index was significantly augmented in tumors of L12 rats compared with L3 and L8 ($p<0.001$), while the apoptotic index was augmented in tumors of L3 versus L12 ($p<0.05$). We observed an increased expression of PCNA in tumors of L12 compared to L8 ($p<0.05$).* The expression of Bax, Bcl2, Bid and caspase 9 were similar in the three groups. However, cleaved caspase 8, was higher in tumors from L3 than L12 ($p<0.01$). All this results indicate that optimal lactation early in life is associated with the activation of the extrinsic apoptotic pathway in mammary tumors. Moreover, we showed a greater cell proliferation of tumors in rats with a deficient lactation (L12). These results are in accordance with the augmented tumor incidence and the tendency of tumors to grow faster in this group of animals.

Keywords: mammary cancer, apoptosis, proliferation, lactation

(123) **THYROID HORMONES INDUCES CHEMOSENSITIVITY TO DOXORUBICIN IN JURKAT CELLS THROUGTH THE MODULATION OF ENZYMES INVOLVED IN CHEMOTHERAPY DRUG METABOLISM**

María Celeste Díaz Flaqué, María Florencia Cayrol, Helena Sterle, Cinthia Rosemblit, Alejandra Paulazo, Johanna Díaz Albuja, Alicia Klecha, Maria Laura Barreiro Arcos, Graciela Cremaschi
BIOMED UCA-CONICET

Thyroid hormones (TH) – 3,3´,5-triiodo-L-thyronine (T3) and L-thyroxine (T4) – are important regulators of the metabolism and physiology of most normal tissues. We recently showed that TH stimulate the proliferation and metabolism of T cells.

To assess the effect of TH on the response to conventional chemotherapy, we determined the Doxorubicin (DOX) dose that inhibits proliferation by 50% (IC_{50}) in presence or absence of TH. As expected, DOX induces cytotoxicity in a dose-dependent manner in cells treated or not with TH. It is important to note that under proliferative conditions, pretreatment with TH sensitizes Jurkat cells to DOX treatment. Noteworthy pretreatment with TH significantly decreases chemosensitivity to DOX by 50% ($p<0,01$). It is well known that CYP3A4 is the major enzyme involved in the metabolism of chemotherapeutic drugs. We have previously demonstrated that TH induce a significant increase of CYP3A4 mRNA synthesis, protein expression and metabolic activity through both the canonnical (TR) and membrane (integrin $\alpha v\beta 3$) receptors. We reasoned that TH-induced CYP3A4 modulation may act as an important regulator in the metabolisms of DOX. To further explored the role of CYP3A4 in TH-chemosensitivity to DOX we used siRNA knock down of CYP3A4 in Jurkat cells. As expected, in CYP3A4 knocked down cells, no TH-mediated chemosensitivity was observed. We also found that TH modulate these functions by activating the membrane receptor integrin $\alpha v\beta 3$. We found that inactivation of integrin $\alpha v\beta 3$ by either a chemical inhibitor or siRNA inhibit TH-induced DOX chemosensitivity.

These results present a new mechanism by which TH could modulate chemotherapy response. These findings highlight the importance of evaluating thyroid status in patients during application of T cell lymphoma therapeutic regimens.

(213) **DEVELOPMENT OF BIOTECHNOLOGICAL STRATEGIES INVOLVING CDPKS AND PGPB TO GENERATE POTATO PLANTS TOLERANT TO SALINITY AND *Phytophthora infestans***

Cecilia Eugenia María Grossi, Elisa Fantino, Franco Santin, Rita Ulloa
INGEBI-CONICET

Abstract: Salinity of soils affects plant development and is responsible for great losses in crop yields. Potato plants can grow well in soils with an electrical conductivity (EC) of 1,7 dS/m, however tuber yield decreases more than 50% at 5.9 dS/m. Calcium is a universal second messenger that responds to biotic and abiotic stimuli. Calcium dependent protein kinases (CDPKs) sense the fluctuation in cytosolic Ca2+ levels and participate in stress responses. Particularly, StCDPK2 promoter contains elements responsive to ABA, dehydration and desiccation. Transgenic plants 35S::StCDPK2 lines B and E presented higher biomass and greater root development under 50 mM NaCl. In order to compare the expression profile of CDPK2 in both normal and saline conditions we analyzed two transgenic lines (St2B and St2K) harboring reporter gene beta-glucuronidase (GUS) under the control of CDPK2 promoter. These plants were grown in solid MS media (2% agar) and were then treated with 150 mM NaCl for 1, 4 and 12 hours. Histochemical and fluorometrical GUS activity was conducted in leaves and roots. GUS activity was higher on the cells of the root cap under saline stress. Fluorometrical analysis correlated with this observation in line St2B. On the other hand, line 35S:CDPK2 A that exhibited a stronger tolerance to saline stress presented bacterial colonies associated to the root. The microorganism was isolated and 16S rDNA partial sequencing identified it as belonging to *Methylobacterium sp*. Treatment with 50 mM NaCl produced a reduction in chlorophyll content and root development which was mitigated with *Methylobacterium* inoculation. Moreover, a preliminary study showed its capacity to antagonize the phytopathogenic oomycete *Phytophthora infestans* the causal agent of late blight. Taken together, our results suggest that potato StCDPK2 could mediate the response to salt stress and that this plant growth promoting bacteria (PGPB) could play a significant role in saline tolerance and biocontrol.

(1851) **ADVANCES IN THE FUNCTIONAL STUDY OF THE *ARABIDOPSIS* DNA GLYCOSYLASE MBD4L**

Jose Roberto Torres, Ignacio Lescano, Maria Elena Alvarez
Centro de investigaciones en Química Biológica de Córdoba (CIQUIBIC, CONICET-UNC), Departamento de Química Biológica, Facultad de Ciencias Químicas, Universidad Nacional de Córdoba

DNA glycosylases play important roles in the life of all organisms, acting at initial stages of the base excision DNA repair system that excises and replaces damaged bases from DNA. Interestingly, some particular DNA glycosylases remove 5-methylcytosine (5-mC), whose replacement by cytosine (C) can produce DNA demethylation. In Arabidopsis, DNA glycosylases from the DEMETER family have such capacity, and act over some well characterized targets. Here, we studied a novel DNA glycosylase recently described named MBD4L (methyl-binding domain protein 4 like), that is homologous to the human DNA glycosylase MBD4. Curiously, MBD4L does not recognize 5-mC *in vitro*. Even so, we evaluated if MBD4L can affect DNA methylation of some particular genomic regions. For that, we selected genomic targets with different chromatin states (euchromatic- heterochromatic) and used CHOP-PCR assays to determine their methylation level. Studies were conducted in wild-type, *mbd4l* mutant and MBD4L over-expressing plants, under both basal and stress conditions. We found that MBD4L controls DNA methylation at loci having different chromatin states. Moreover, the enzyme affects DNA methylation both at basal and stress condition. These results suggest that the action of MBD4L is not restricted to a particular chromatin state and probably contributes to stress-induced responses. The putative effects of MBD4L on the different genomic sites and on transcriptional regulation will be discussed.

Keywords: epigenetics, DNA demethylation, chromatin state, gene expression, DNA glycosylases, stress.

(1610) **CHANGE IN LIPID COMPOSITION OF *Bradyrhizobium* CELL ENVELOPED REVEAL A RAPID RESPONSE TO WATER DEFICIT INVOLVING LYSOPHOSPHATIDYLETHANOLAMINE SYNTHESIS IN OUTER MEMBRANE**

Adriana Cesari, Natalia Paulucci, Alicia Biasutti, Marta Dardanelli
Universidad Nacional de Río Cuarto

Cell enveloped is the primary targets affected by variations in the medium. Membrane behavior of *Bradyrhizobium* sp. SEMIA6144 during adaptation to water deficit induced by polyethylene glycol (PEG) was evaluated. *B.* sp. SEMIA6144 was exposed to PEG shock (1 h, 5 h and 24 h).

To investigate if PEG caused changes in cell morphology we used AFM. Fractions of internal and external cell membrane were obtained and lipids were extracted. The fatty acids (FA) were analyzed by GC and phospholipid (PL) were identified by TLC. For its quantification, [1-14C] sodium acetate was added to culture. Fluidity membrane cell and multilamellar vesicles (MVLs) from lipids cell was determined by measuring fluorescence polarization of DPH. To determine the PLA activity during PEG shock, outer membrane was used as enzyme source.

A dehydrating effect on the morphology of the cell surface as well as a fluidizing effect on the membrane was observed 10 min after PEG shock ($p<0.05$). The bacteria were able to restore optimal membrane fluidity. MVLs exposed to 1 h shock presented higher

rigidity compared to the control ($p<0.05$). A rapid response (1 h) was mediated by an increase in lysophosphatidylethanolamine (LPE) ($p<0.05$) at the expense of phosphatidylethanolamine(PE) ($p<0.05$) and an increase in saturated fatty acids ($p<0.05$). After 5 h and 24 h of PEG shock, the amount of LPE decreased ($p<0.05$) while PE increased ($p<0.05$). Shock of 1 h caused an increase of LPE ($p<0.05$) in the outer membrane through an increase in PLA activity ($p<0.05$) on PE. LPE amount did not remain constant during the shock. The inner membrane composition showed an increase of PC at the expense of PE ($p<0.05$) after 1 h of shock. However, the proportions of these PL reach values similar to the control after 24 h of shock.

Our results suggest that during PEG shock, the membranes composition of *B.* sp. SEMIA6144 is rapidly remodeled to counter fluidizing effect; then, this response is dynamically modified via PL turnover.

(538) **GENERALIZED MUTAGENESIS AND TAIL-PCR FOR THE IDENTIFICATION OF COMPONENTS INVOLVED IN THE INVERSE REGULATION BETWEEN T3SS AND MOTILITY IN *Mesorhizobium loti***

Ana Clara Gonzalez, Laura Ana Basile, Viviana Claudia Lepek
IIB-UNSAM

Mesorhizobium loti presents a type 3 secretion system (T3SS) that is involved in the determination of bacterial competitiveness for the nodulation of *Lotus* spp. It was found that TtsI, the transcriptional factor that induces T3SS expression, inhibits bacterial motility in soft agar plates. This effect is accompanied by a down regulation of flagellar genes and flagella production. Besides, it was found that T3SS must be localized in membrane for that inhibition to occur. The objective proposed was to determine which mechanisms are involved in the motility inhibition. A generalized mutagenesis was performed by using mini-Tn5 transposon in order to isolate mutants that do not show this inhibition under T3SS induction conditions. A bacterial suspension was inoculated in soft agar plates containing naringenin (for T3SS induction) and those mutants that presented a higher motility were transferred to a new motility plate. After 5-6 passages, isolated colonies were obtained. In order to identify the gene in which the transposon was inserted, a TAIL-PCR method was performed for each mutant. We used a combination of random primers and transposon specific primers for the amplification of the region flanking the Tn5 sequence. By the evaluation of the presence or absence of the pili protein in culture supernatants, as indicative of T3SS functionality, mutants are being classified in two groups, those which the mutation affected a component of the T3SS and those in which a different gene was affected.

(1593) **GENERATION OF HYBRID BACTERIOCINS VARIANTS WITH ENHANCED ANTIMICROBIAL ACTIVITY**

Silvia Adriana Navarro, Miguel Fernandez De Ullivarri, Lucia Lanza, Augusto Bellomio, Miriam Carolina Chalón
Instituto Superior de Investigaciones Biológicas

Bacteriocins are bacterial antimicrobial peptides of ribosomal synthesis active on phylogenetically related microorganisms. The chimerical BACTERIOCIN-HINGE-MICROCIN named PedA1-GGG-ColV and Ent35-GGG-MccV are new hybrid peptides with broader antimicrobial spectrum than the parental molecules. Based on the hypothesis that changes in the hinge connecting the bacteriocins could improve the activity of the hybrids, the inter-peptide region was subjected to gene-based bioengineering to generate novel derivatives with enhanced bioactivity. In this work, we generate a bank of randomly mutated hybrid bacteriocin genes by saturation mutagenesis. The employed site-directed saturation mutagenesis method uses two primers containing a degenerate mixture of the four bases at the central codon of the three-amino-acids hinge-encoding region. These primers were added to starting plasmid template and thermal cycled to produce mutant DNA plasmids, which were subsequently transformed into competent *Escherichia coli* DH5α. The plasmid DNA was purified from all the obtained colonies and the preparation containing a plasmid mix was analyzed by DNA sequencing. Approximately equal quantities of the four bases were seen at each position of the mutated codon. The plasmid mixture was used to obtain an expression library in *E. coli* BL21. One hundred colonies were randomly selected and the expression of hybrid peptides was further induced with 0.01 mM IPTG. The antimicrobial activity of cellular extracts was determined against the Gram (+) and Gram (-) indicator strains (*L. monocytogenes* FBUNT and *E. coli* MC4100). Some of the extracts showed higher antibiotic activity compared to the Ent35-GGG-MccV extract (parental hybrid). In particular, the extract obtained from the strain SN35 was four times more active on both *E. coli* and *L. monocytogenes*. The approach was highly successful to obtain mutants with improved bioactivity with respect to the original hybrids.

(211) **STNDPK3 IS A MITOCHONDRIAL NUCLEOSIDE DIPHOSPHATE KINASE FROM *Solanum tuberosum***

Elisa Fantino, Cecilia Eugenia María Grossi, Franco Santin, Marcelo Sciorra, Rita María Ulloa
INGEBI-CONICET

Abstract: Nucleoside diphosphate kinases (NDPKs) are capable of altering the set of nucleoside triphosphates, participating in the intracellular energy communication network and have been described in several signaling cascades associated to stress responses in plants. Plant NDPKs are organized in four distinct types (I to IV) according to their subcellular localization and their phylogenetic relationships. The cytosolic isoform Type I NDPK (NDPK1) has been shown to be the major NDPK isoform in plants (Dorion et al., 2006). An *in silico* search of the*Solanum phureja* genome (PGSC) and ClustalW alignment with NDPKs from other plants, animals and microorganisms allowed us to identify two chloroplastic (type II) and two mitochondrial (type III) isoforms that belong to group I and one secreted isoform (type IV) that belongs to group II. In this work we characterize one of the potato mitochondrial isoforms. The complete coding sequence of StNDPK3 was cloned from potato sprouts and the recombinant protein was expressed. The analysis of its expression profile reveals that it is an ubiquitous isoform. RT-qPCR assays of plants infected with *Phytopthora infestans* suggest that it could be involved in biotic responses.

Herbicide-resistant weeds is one of the main problems of modern agriculture. Timely diagnosis is crucial for resistance management and mitigation, so confirming resistance in weed populations requires rapid and accurate methods to identify resistant biotypes. Bioassays are commonly used for detecting resistances. However, these methods are laborious, time consuming and do not discriminate between different mechanisms of resistance. When target site resistant mechanism is involved, it is possible to develop DNA-based assays, and thus, the polymerase chain reaction (PCR) technique can be used to detect resistant genotypes.

In this work, we cloned the CT domain of the plastidic acetyl-coenzyme A carboxylase (ACCase) encoding gene, target enzyme of herbicides group A, from a subpopulation of *Sorghum halepense* found in production fields of Gobernador Crespo (Santa Fe province). This subpopulation showed a resistance factor higher to 14.41 to haloxyfop-p-methyl (FOP) compared to a susceptible subpopulation from Zavalla (Santa Fe province).

The study of the sequences from bulks of genomic DNAs allowed to identify two alleles in the resistant subpopulation. The R1 allele carries the previously reported substitution (I2041N) as responsible for the resistance to FOP, and the R2 allele has a novel mutation that

could contribute to the resistance phenotype. To evaluate this last hypothesis, genetically identical Johnsongrass plants were obtained by clonal dispersion of rhizome after the application of the herbicide at the field dose. Then, these vegetative clones were subjected to specific allele PCR assays to screen the presence of each allele and to characterize the individual phenotype.

Accordingly, a simple method based on allele-specific PCR was developed to detect point mutations in the *accase* gene, allowing the rapid identification of different models of studies to elucidate resistance mechanisms.

Detection of $NADP^+$/NADPH in living organisms is a major analytical resource in biology. However, available methods are not efficient enough and are not able to distinguish existing levels in different cellular compartments. In this work, a non-invasive sensor was designed to determine the $NADP^+$/NADPH fraction based on the ratiometric properties of roGFP2: a GFP variant sensitive to reduction/oxidation which has two fluorescence excitation maxima at 390 and 485 nm and shows reversible ratiometric changes at 510 nm emission both *in vitro* and *in vivo*, responding to thiol-containing redox metabolites. We designed a biosensor to determine the cellular redox state of NADP(H), by fusing roGFP2 to the coding region of rice NADP(H)-thioredoxin reductase C (NTRC) by spacer arms of variable lengths. The resulting construct, NTRC-roGFP2, was expressed in *Escherichia coli* strains which over-express molecular chaperones, and purified by affinity chromatography. Fluorescence ratios reflecting NTRC-roGFP2 redox state varied with NADP(H) concentrations, indicating that NTRC-roGFP2 is capable to poise with NADP(H) and works as a sensor, therefore translating pyridine-nucleotides redox variations to the universe of thiols. The redox potential of this couple was determined by fluorescence measurements of the sensor redox status, applying the Nernst equation adapted to the $NADP^+$/NADPH pair.

The biosensor was also characterized by studies *in vivo* in tobacco plants and bacteria using confocal microscopy. Measurements on *E. coli* were assayed in cultures that were grown in defined minimal media as well as in anaerobic conditions. Concurrently, we are also working to improve electronic exchange between NTRC and roGFP2, to achieve a more efficient detection which can be then used for the study of fundamental redox mechanisms in living beings.

Keywords: biosensor, fluorescence, redox potential, NADP(H)

(843) **STRUCTURAL AND FUNCTION ANALYSES OF D199A MUTATION PROVIDE NEW INSIGHT INTO *XCC*BPHP BACTERIOPHYTOCHROME SIGNALING IN *XANTHOMONAS CAMPESTRIS PV. CAMPESTRIS***

Valeria Paola Conforte (1), Hernán Ruy Bonomi (2), Lisandro Otero (2), Jimena Rinaldi (2), Sebastián Klinke (2), Fernando Goldbaum (2), Adrián Vojnov (1), Florencia Malamud (3)

Many organisms possess photoreceptors that are capable of detecting light wavelengths and transduce this information within cells. Phytochromes constitute a major superfamily of light-sensing proteins that are reversibly photoconverted between a red-absorbing (Pr) and a far-red-absorbing (Pfr) state. *Xanthomonas campestris* pv. *campestris* (*Xcc*), the causal agent of black rot disease, codes for a functional bacteriophytochrome (*Xcc*BphP). Previous work of our group have demonstrated that *Xcc*BphP is a bathyphytochrome that acts as a negative regulator of virulence. Here, we go deeply into the study of the *Xcc*BphP structure and function. In this work, we analyze the role of the conserved residue Asp_{199} located in the photosensory domain, which is crucial for photochemical Pr-to-Pfr conversion. For this aim, we purified the recombinant *Xcc*BphP-D199A full-length mutant, crystalized it and solved the crystal structure, revealing a Pr state identical to the wild-type Pr structure. We also evaluated its UV-Vis absorption spectroscopic properties showing that this mutation locks *Xcc*BphP in Pr state. Once the effect of the mutation was established, we tested the effect of D199A during infection. We first complemented an *Xcc*bphP null mutant strain with *Xcc*BphP-D199A (D199A). We inoculated 10-day-old *Arabidopsis* plant seedlings with bacterial strains cultured under red, far-red or dark conditions. After 2 days p.i., bacterial CFU per plant mg were determined. We found that D199A was less virulent than the wild-type and the *XccbphP* strains in all cases regardless of the light treatment. D199A ability to infect plants remained comparable to null mutant strain carrying the plasmid with an intact *XccbphP* copy. Exopolysaccharide production, a known virulence factor, correlated with the infection results. Taken together, these results indicate that D199A mutation locks *Xcc*BphP in an activated Pr-like state, irresponsive to light, inhibiting virulence factors and plant infectivity.

(468) **DEVELOPMENT OF METHODS TO VALIDATE SYNTHETIC LETHALITY INDUCTION *IN VITRO* AND *IN VIVO***

Andrés Castellaro, Ayelen D. Nigra, Sofia Carbajosa, María Celeste Rodrguez-Baili, Lucía Rodriguez-Berdini, Ana C. Racca, María Florencia Pansa, Alejandra I. García, Germán A. Gil, Gastón Soria

CIQUIBIC-CONICET, Departamento. de Química Biológica, Facultad de Ciencias Químicas, Universidad Nacional de Córdoba.

One of the current challenges in the development of anticancer therapies lies in the identification of drugs that selectively kill cancer cells with minor impact on normal cells. A strategy of selective cytotoxicity that has yielded promising results is the induction of synthetic lethality (SL). SL induction involves tumor-acquired mutations that sensitize cells to a given treatment when they are in combination. We are focused in the study of drugs that cause SL in BRCA1/2-deficient cancer cells (Bd-cells). Herein we show the validation of potential drugs which have been previously identified as SL-inducers using a cell-based high-throughput screening platform based on flow cytometry. Three validation methods were developed to assess the performance of these drugs on a Bd-cell model in comparison to the wild type cell line (Bw-cells). The first method evaluates the clonogenic potential of Bd-cells and Bw-cells after the treatment with the drugs, using an adaptation of the colony formation assay. The second method involves the use of 3D chimeric spheroids constituted by an equal proportion of Bd-cells and Bw-cells. Both cell populations are tagged with different fluorescent proteins and can therefore be quantified by flow cytometry after the treatments with the drugs. The third model is a double tumor xenograft approach in Nude mice. This model consists in the generation of flanking tumors in a single mouse, one from Bd-cells and the other from Bw-cells. Mice are then treated with potential SL-inducers or vehicle and the progression of each tumor-type is assessed in order to expose the SL phenomena *in vivo*.

(521) **NUCLEAR TRANSLOCATION OF PROTEINS *VIA* IMPORTIN PATHWAY IN PROTOZOAN PATHOGEN *TRYPANOSOMA CRUZI***

María Laura Kevorkian (1), Ezeogo Obaji (2), Salomé C. Vilchez Larrea (1), Lari Lehtiö (2), Silvia H. Fernández Villamil (1)

(1) INGEBI-CONICET-UBA. (2) Biocenter Oulu and Faculty of Biochemistry and Molecular Medicine, University of Oulu, Finland.

In higher eukaryotes, active transport of proteins to the nucleus

occurs through the nuclear pore complexes (NPCs), directed by nuclear localization signal (NLS) sequences. The NLS is recognized by importin α in the cytoplasm that then binds to importin β which transports this trimeric complex across the NPC. The importin α consists of two functional domains, a short basic N-terminal domain (the IBB domain) sufficient for importin β binding, which also acts as an autoinhibitory domain, and a NLS-binding domain comprised of armadillo (arm) repeats. There is limited amount of information about nuclear protein targeting in lower eukaryotes such as trypanosomatids. Therefore, we aimed to study the importin pathway in *Trypanosoma cruzi* (*T. cruzi*), causative agent of Chagas Disease, using the N-terminal domain of the poly(ADP-ribose)polymerase from *T. cruzi* (TcPARP-NT) as a tool, which is known to be sufficient for nuclear translocation. Through a bioinformatic approach we found a sequence encoding for a putative importin α (TcIMPα) in this parasite. This gene was cloned and expressed as a full length protein (TcIMPα FL) or lacking the IBB domain (TcIMPα ΔIBB). A pull down assay using His-tag capture confirmed binding of TcPARP-NT with TcIMPα ΔIBB. In a Size Exclusion Chromatography this protein complex did not elute together, but by using centrifugal filters, with a cut off higher than the TcPARP-NT molecular weight, binding was observed. In addition, interaction of TcIMPα with TcPARP was confirmed by Bio-Layer Interferometry that enables real-time, label-free analysis for determination of affinity, which resulted in μM dissociation constant. It was established that TcIMPα FL and TcPARP-NT do not bind reinforcing the idea of importin α autoinhibition, also present in the parasite. Taken together, these results give us a first insight into the presence of an operative importin system in *T. cruzi* which could play an active role in protein translocation.

(516) **ROLE OF THE ESCRT COMPLEX IN TRYPANOSOMATIDS: FUNCTIONAL CHARACTERIZATION OF Vps32**

Nadia Maricel Barrera, Tamara Sternlieb, Patricio D. Genta, Milena Massimino Stepñicka, Alejandra Schoijet, Guillermo D. Alonso
INGEBI; CONICET; UBA

The ESCRT (Endosomal Sorting Complex Required for Transport) is a machinery that drives a diverse collection of membrane remodeling events such as endocytosis, multivesicular body biogenesis, autophagy, release of enveloped viruses, reorganization of the nuclear envelope and cytokinetic abscission during mitosis exit. This complex is composed of four subcomplexes (0-III) been ESCRTIII the effector of the complex. Vps32 is the most abundant protein in ESCRTIII and the abscission capability is given for its molecular structure alternating between a monomeric-closed state to polymeric-open state. Here we investigate the conservation of Vps32 in *Trypanosoma cruzi* and *Trypanosoma brucei*. The *Saccharomyces cerevisiae* gene corresponding to the Vps32 (Snf7) was used to screen TriTrypDB databases. We found the *T. cruzi* orthologue (TcVps32) which have two alleles in CL Brener strain: TcCLB.511589.250 (Esmeraldo) and TcCLB.511229.100 (Non Esmeraldo). These sequences were used to screen *T. brucei* database resulting in a high-scored target: Tb427tmp.01.1390. Protein domains, secondary structure and isoelectric point were determinated showing the presence of Snf7 motif, alpha helices with the MIM motif in the last helix and basic N-terminal and acid C-terminal which implies a structure conservation among eukaryotic cells. To perform a functional characterization, TcVps32 coding sequence was amplified by PCR fused to a hemagglutinin tag at N-terminal (HA-TcVps32) or without tag (TcVps32). The PCR products were subcloned into pRIBOTEX and the constructs (pRibo-HA-TcVps32 and pRibo-TcVps32) were transfected in *T. cruzi* epimastigote cells. Simultaneously, in *T. brucei* procyclic form we designed an RNAi strategy where a 405bp of TbVps32 was cloned into the p2T7 vector (TbVps32-RNAi) which allow a tetracycline inducible silencing of this protein. The TcVps32 overexpressing *T. cruzi* epimastigotes and the procyclic form of *T. brucei* transfected with TbVps32-RNAi are under evaluation.

Keywords: membrane remodeling, multivesicular body biogenesis, autophagy, cytokinetic.

(1854) **THE ROLE OF SUMO CHAINS IN NUCLEAR FOCI FORMATION AND CHROMATIN ORGANIZATION IN *Trypanosoma brucei* PROCYCLIC FORMS**

Paula Ana Iribarren, Lucía Ayelén Di Marzio, María Agustina Berazategui, Javier Gerardo De Gaudenzi, Vanina Eder Alvarez
Instituto de Investigaciones Biotecnológicas "Dr. Rodolfo A. Ugalde" (IIB-INTECH) (CONICET-UNSAM)

SUMOylation is a post-translational modification conserved in eukaryotic organisms that involves the covalent attachment of the small ubiquitin-like protein SUMO to internal lysine residues in the target proteins. This tag usually alters the interaction surface of the modified protein and can be translated into changes in its biological activity, stability or subcellular localization, among other possible outputs. SUMO can be attached as a single moiety or as SUMO polymers in case there are internal acceptor sites in SUMO itself. These chains have been shown to be important for proteasomal degradation as well as for the formation of subnuclear structures such as the synaptonemal complex in *Saccharomyces cerevisiae* or promyelocytic leukemia (PML) bodies in human cells.

In this work, we have examined SUMO chain formation in the ancient protozoan parasite *Trypanosoma brucei*. Using a recently developed bacterial strain engineered to produce SUMOylated proteins we confirmed the ability of *Tb*SUMO to form polymers and determined the type of linkage using site-directed mutational analysis. By generating transgenic procyclic parasites unable to form chains we demonstrated that although not essential for normal growth, SUMO polymerization determines the localization of the modified proteins at the nuclear periphery. In addition, FISH analysis of the telomeres showed a differential localization depending on the polySUMOylation abilities of the cells, and MNase accesibility assays revealed structural changes in the chromatin. A bioinformatic analysis showed that the *T. brucei* proteome contains about a hundred of good SUMO interactor candidates. Specifically, these proteins are sequences containing SUMO interactive motifs enriched in nuclear processes. Thus, our observations indicate that SUMO chains play an important role in establishing interaction platforms at the nuclear periphery likely contributing to chromatin organization.

(1095) **UNRAVELLING THE FUNCTION OF THE UNIQUE N-TERMINAL DOMAIN OF *TRYPANOSOMA CRUZI* HIGH MOBILITY GROUP B PROTEIN.**

Luis Tavernelli, Victoria Lucía Alonso, Alejandro Pezza, Esteban Serra, Pamela Cribb

High Mobility Group B (HMGBs) are a family of chromatin proteins capable of binding non-canonical DNA structures through one or more "HMG box" domains. These proteins are highly conserved among eukaryotic organisms and are involved in key nuclear processes like transcription, replication, recombination and DNA repair. The HMGB from *Trypanosoma cruzi* (*Tc*HMGB) contains two "HMG box" domains and a unique N-terminal sequence present only in trypanosomatids' HMGBs. *In silico* studies showed that within this region there is a nuclear localization signal (NLS) and a DEK-C terminal domain, a putative third DNA-binding domain in trypanosomes´ HMGBs.

We obtained parasites capable of overexpressing truncated forms of TcHMGB (N-terminal domain and *Tc*HMGBΔN) and the full length *Tc*HMGB as well. Immunofluorescence assays showed that the wild type version is located in the nucleus but when we overexpressed TcHMGB lacking the N terminal domain (*Tc*HMGBΔN) the protein is distributed along the whole parasite but excluded from the nucleus. On the other hand, when we overexpressed only the N-terminal region, this fragment accumulated in the nucleus but also it was detected in the cytoplasm. These results suggest that the NLS is necessary but not sufficient to drive the protein to the nucleus.

We previously determined that overexpression of TcHMGB results in changes in chromatin structure that is detrimental for the parasite fitness. We now evaluated the effect of overexpressing the N-termi-

nal region alone, which caused a dramatic decrease in epimastigotes growth. In order to clarify this phenotype we analyzed the cell cycle by flow cytometry with synchronized cultures in the G1 phase, showing a clear delay in the cell progression compared to the negative control. *In vitro* infection assays showed that amastigotes replication can also be affected. We propose that the DEK-C terminal domain may be another contact point of TcHMGB with nuclear DNA contributing to chromatin structure remodeling.

Key words: TRYPANOSOMA CRUZI, DEK-C, NLS, CHROMATIN.

(561) **PROTEOMIC ANALYSIS OF EXTRACELLULAR VESICLES FROM *Trypanosoma cruzi* TRYPOMASTIGOTES REVEALED THAT CONTAIN A LARGE AMOUNT OF PROTEINS INVOLVED IN PATHOGENESIS**

Lucas D. Caeiro, Valeria S. Tekiel
Instituto de Investigaciones Biotecnológicas - Instituto Tecnológico de Chascomús, Universidad Nacional de San Martín - CONICET, San Martin, Buenos Aires, Argentina.

The trypomastigote is the circulating bloodstream and non-replicative stage of *Trypanosoma cruzi*, the causative agent of Chagas disease. Many of the surface proteins of the trypomastigote, involved in cell invasion and/or in the infection process, are also secreted. We have previously found that trypomastigotes secrete into extracellular vesicles (EVs) virulence factors that should be hidden from the immune system. Data currently available from exoproteomes were derived from total secreted material (free and vesicle-contained, Y strain) or from a mixture of EVs from parasites and host cells (Tulahuen strain). Here we present a proteomic analysis of trypomastigote EVs (reference CL Brener strain), to search for putative virulence factors secreted into trypomastigotes EVs. To isolate EVs, conditioned media from cell-derived trypomastigotes were sequentially ultracentrifugated to obtain, after 2 and 16 hs, EVs fractions V2 and V16, respectively. Both fractions were analyzed in a Q Exactive HESI-Orbitrap coupled to a nano HPLC Easy-nLC 1000. MS/MS data were used to search *T. cruzi* database (Tritrypdb.org, v.30). Each EV subpopulation presented a differential set of major proteins (V2: n=270; V16: n=228), and a minor core of 142 common proteins. GO Analysis (UniprotKB) revealed that V2 and V16 had mostly proteins involved in pathogenesis (37,8%; 56,7%) and cellular process (22,1%; 12%). We also found known virulence factors like KMP-11, several members of multigene families (TS, TcTASV) and immune system modulators (i.e. TcHMGB), some of them were among the common core like TcTASV-C, TS group I and TolT. This data demonstrate that EVs contain a large number of key proteins involved in multiple regulatory and pathogenic processes. Characterization of trypomastigote EVs cargo may be helpful to identify novel vaccine or drug targets for the control of Chagas disease.

(293) **ANALYSIS OF THE NADPH CYTOCHROME P450 REDUCTASE GENE: ITS RELATIONSHIP WITH PYRETHROID RESISTANCE IN THE CHAGAS DISEASE VECTOR *Triatoma infestans***

Gonzalo Matías Varela, María Mercedes Stroppa, Carla Gisela Grosso, Beatriz Alicia García
INICSA, CONICET y Cátedra de Bioquímica y Biología Molecular, Facultad de Ciencias Médicas, Universidad Nacional de Córdoba, Argentina.

Abstract: Pyrethroid resistance has been detected in the Chagas disease vector *Triatoma infestans* (Hemiptera: Reduviidae), which has been attributed to target site insensitivity and increased oxidative metabolism of the insecticide by cytochrome P450s. NADPH cytochrome P450 reductase (CPR) plays an essential role in transferring electrons from NADPH to the P450-substrate complex. In this study, the full length CPR cDNA of *T. infestans* was isolated and gene expression was determined by quantitative PCR. The open reading frame is 2046 bp long, encoding a protein of 682 amino acids. Amino acid sequence analysis indicates that the *T. infestans* CPR and the putative *Rhodnius prolixus* and *Triatoma dimidiata* CPRs, present conserved ligand-binding domains. The expression of the CPR gene at transcriptional level was determined in muscle, heads, gonads and fat body of fifth instar nymphs and adults. In both stages, gonads and fat body presented significant levels of expression. It was detected a higher level of expression in gonads of nymphs than in adults, while the fat body presented a higher level of expression in adults. On the other hand, congruently with a previous study of our laboratory, in which the expression of three cytochrome P450 genes (CYP4EM7, CYP3085B1, and CYP3092A6 genes) was induced by deltamethrin, the levels of *T. infestans* CPR mRNA were up-regulated in the fat body of fifth instar nymphs after topical application of deltamethrin. Besides, similarly to the observed in the CYP4EM*7* gene, it was detected overexpression of the CPR gene in the most resistant strain of *T. infestans* included in the study. These results suggest that CPR plays an essential role in P450-mediated resistance of *T. infestans* to insecticides.

Keywords: chagas disease, *Triatoma infestans,* pyrethroid resistance, CPR gene

(305) **ANALYSIS OF THE CLOCK GENES PERIOD AND TIMELESS IN CHAGAS DISEASE VECTORS**

María Mercedes Stroppa, Sonia Diaz, Beatriz Alicia Garcia
INICSA, CONICET y Cátedra de Bioquímica y Biología Molecular, Facultad de Ciencias Médicas, Universidad Nacional de Córdoba, Argentina.

In *Rhodnius prolixus* and *Triatoma infestans* circadian rhythms seem to control basic biological processes. In order to better understand the molecular bases of the circadian rhythms, we explored the biological central clock at the molecular level in triatomine insects. With this purpose, we identified coding regions of the clock genes *period* (*per*) and *timeless* (*tim*) from the genome of *R. prolixus* and analyzed their expression at mRNA level in *T. infestan*s. The *per* and *tim* genes expression in nervous tissue of adults *T. infestans* varies with a daily rhythm in groups of individuals maintained under photoperiod (LD), showing a significant peak of expression at sunset. These rhythms of expression agrees with those described in *Drosophila melanogaster* and would be compatible with the daily oscillation in the levels of PER and TIM proteins detected by other authors in *R. prolixus*. Contrary, in the group maintained under constant light (LL), no daily increase were detected in *per* and *tim* transcript level. This result suggests a disruptive action of light in the transcription of the clock genes *per* and *tim*. Besides, the presence of *per* transcript in different tissues of adult individuals and in nervous tissue of nymphs evidenced activity of peripheral and central clocks in adults and activity of the central clock in nymphs of *T. infestans*.

Keywords: Chagas disease, vectors, clock genes, *period* and *timeless*.

IMMUNOLOGY (ADAPTATIVE IMMUNITY) 1

(466) **REGULATION OF DENDRITIC CELLS INTRACELLULAR TRAFFICKING BY SNX17 DURING ANTIGEN CROSS-PRESENTATION**

Sofía Dinamarca, Alejandro Zalazar, Cristina Croce, Luis Mayorga, Ignacio Cebrián
IHEM-CONICET

Cross-presentation by MHC class I molecules allows the detection of exogenous antigens by CD8+ T lymphocytes. This process is crucial to initiate cytotoxic immune responses against many pathogens (i.e. *Toxoplasma gondii*) and tumors. To achieve efficient cross-presentation, dendritic cells (DCs) have developed highly specialized adaptations of their endocytic network. Consequently, DCs are the most potent antigen presenting cell type to accomplish this immunological process. However, a complete view of the many molecular effectors involved in antigen cross-presentation is still missing. Sorting nexin (SNX) proteins are characterized by the presence of a phox-homology (PX) domain that interacts with elements of the endocytic pathway enriched with phosphatidylinositol-3-monophosphate. In this way, SNXs control key features of endocytosis, as well as endosomal signaling, sorting and tubulation. In this study, we fo-

cus on the role of SNX17, which associates with compartments of the early endocytic network and participates in several processes of intracellular recycling. Here, we identify SNX17 as a crucial regulator of antigen cross-presentation by DCs. By silencing the expression of SNX17 with shRNAs, we evaluated in DCs the role of this molecule in the fast and slow recycling pathways by flow cytometry. Furthermore, the knock-down of SNX17 hampered the cross-presentation of soluble, particulate and *T. gondii*-associated antigens. Our results also demonstrate that SNX17 is actively recruited to the vacuole containing *T. gondii* parasites in DCs, as observed by immunofluorescence labelling and confocal microscopy analysis. Our findings provide compelling evidence that SNX17 plays a central role in the endocytic trafficking of DCs and is crucial to guarantee an efficient antigen cross-presentation.

Keywords: Dendritic cells, cross-presentation, SNX17, recycling, *Toxoplasma gondii*.

(192) **CHARACTERIZATION OF TONSILLAR IL10 SECRETING B CELLS AND THEIR ROLE IN THE PATHOPHYSIOLOGY OF TONSILLAR HYPERTROPHY**

Lindybeth Sarmiento Varon (1), Javier De Rosa (1), Ariel Billordo (1), Placida Baz (1), Pablo Fernandez (1, 2), Andres Blanco (3), Eloísa Arana (1, 2)

(2) Department of Immunology, School of Medicine, University of Buenos Aires. (3) Institute of Otolaringology Arauz, Buenos Aires, Argentina.

The immune actions of tonsillar B cells (Bc) must be tightly regulated to balance the protection against virulent germs and the tolerance to harmless flora and innocuous Ags in food and air. Despite the logic of such presumption, the potential role of tonsils in oral tolerance induction has not been completely elucidated so far. The aim of our work was to test the ability of tonsillar Bc to secrete IL10 (regulatory cytokine) and to assess the physiological relevance of this population. All measurements were done by FACS. We determined the phenotype of tonsillar IL10 secreting Bc (tBregs). Also, we found that the frequency of tBregs as determined by FACS upon 72 hs stimulation *ex vivo,* via TLR9 and CD40L, depended on the cause of surgery. The hypertrophied (HT) tonsils´ samples showed a significantly ($p<0.05$) lower percentage of tBregs (4.4±0.4) compared to those from recurrent tonsillitis (RT, 9.9±1.5) as well as a significantly ($p<0.05$) higher proportion of the germinal center (GC) population (23.8±4.3) than those from children with RT (7.9±1.8). A comparative increment of the GC percentage was not accompanied by a proportional growth of the memory B cell population in those HT samples. In contrast, these samples displayed a significantly ($p<0.05$) lower percentage of the eBm5 subset (7.8±0.5) than RT samples (15.5±2.1), indicative of a putative blockade between the GC and memory B cell stages on HT patients. Collectively, our results demonstrate that a defective tBregs compartment indicates an increase in the proportion of GC *in vivo* and therefore unrestrained Tfh function, suggesting that Tfh are a target population of tBreg function. Finally, tBreg modulated TNFα intracellular expression by CD4+ cells in co-cultures of autologous tonsillar lymphocytes. Our findings provide greater insight into the role of tBregs in GC reactions and characterized for the first time their involvement in the pathogenesis of tonsillar dysfunction.

(202) **CHARACTERIZATION OF CYTOKINE SECRETING B CELL SUBPOPULATIONSIN HUMAN TONSILS**

Javier Enrique De Rosa (1, 2), Lindybeth Sarmiento Varon (1), Ariel Billordo (1), Placida Baz (1), Pablo Fernandez (1, 3), Andres Blanco (4), Karina Pasquevich (2, 5), Eloísa Arana (1, 3)

(1) Institute of Immunology, Genetics and Metabolism (INIGEM), Clinical Hospital, University of Buenos Aires, National Council for Scientifc and Technological Research, Buenos Aires, Argentina. (2) Universidad Nacional de San Martín. (3) Department of Immunology, School of Medicine, University of Buenos Aires, Buenos Aires, Argentina. (4) Institute of Otolaringology Arauz, Buenos Aires, Argentina. (5) Instituto de Investigaciones Biotecnologicas (IIB-INTECH).

Tonsils are secondary lymphoid organs which must grant immunologic protection against pathogens and tolerance against inoffensive Ags in air and food. They are mostly B-cell (Bc) maturation and differentiation sites. Bc are able to secrete multiple cytokines under different stimuli, independently of their role as Ag presenting and Ab producing cells. It is likely that alteration of the immune equilibrium activation/regulation may trigger recurrent tonsillitis (RT) and/or hypertrophy (HT) leading in turn to tonsillectomy. Hence, the aim of our work was to characterize such unconventional immune functions of tonsillar Bc, *i.e* different Bc subsets with regulatory and pro-inflammatory profiles, within the human oropharyngeal cavity. All measurements were done by FACS. We determined tonsillar Bc expression of IL6, IL8, IFNγ, IL5, TNFα, IL21, IL10 and TGFβ at different time-points post stimulation. Also, we established the kinetics of appearance of IL10 (regulatory cytokine) expressing Bc (B10) and compared it with that of pro-inflammatory cytokine-expressing Bc (IL6 and IL8) for 5 patients upon 0; 16; 32 and 72 hs stimulation, via TLR9 and CD40L. The proportion of B10 increased between 16 and 72 hs in all cases. Notably, the percentage of B10 detected at the different time points depended on the cause of surgery, an issue that is addressed in a different poster in the same Congress. The results varied across individuals; hence, we showed the contour plots of a single patient and graph lines plotting the results of 5 different patients for the cytokine kinetics. Importantly, we also found a relevant proportion of IL17-expressing B cells in tonsils which is, to our knowledge, the first time that is reported in literature. Collectively, these results demonstrate that despite disease-associated changes, Bc from those damaged tonsils preserve their immune competence to secrete a number of cytokines. This study advances our understanding of the immune functions of the tonsils.

(1282) **LOW TLR9 EXPRESSION IN ADAPTIVE CELLS PROTECTS AGAINST PROGRESSION OF NONALCOHOLIC FATTY LIVER DISEASES**

Nadia Soledad Alegre (1), Cecilia Claudia Garcia (1), Luis Ariel Billordo (1), Javier Benavides (2), Luis Colombato (2), Daniel Poncino (3), Daniel García (3), Alejandra Claudia Cherñavsky (1)

(1) Instituto de Inmunología, Genética y Metabolismo, Hospital de Clínicas "José de San Martín". (2) Sección Hepatología, Servicio de Gastroenterología, Hospital Británico de Buenos Aires. (3) Sección Hepatología, Sanatorio Méndez ObSBA.

T cells play a key role for the progression of Nonalcoholic Fatty Liver Diseases (NAFLD). Signaling through toll-like receptors (TLR) co-stimulates activation/ differentiation and generation of memory T cells. No study correlates clinical facts of NAFLD patients with TLR9 expression and functionality of adaptive cells. We aimed to study TLR9 expression in peripheral and liver adaptive cells during NAFLD progression, its link with metabolic changes and the differentiation of effector and memory cells. Biochemical/anthropometric parameters were measured. PBMC were obtained by Ficoll-hypaque gradient and liver cell suspensions by mechanical disruption. Cells were stained with anti-CD4, -CD8, -TLR9 or -IFNg mAbs and studied by flow cytometry (FC). Analysis of $CCR7^{+/-}$ subpopulations of $CD4^+$ and $CD8^+$ memory cells was performed after negative selection of CD45RO cells. Mann-Whitney, Kruskal-Wallis and Spearman´s correlation tests were used. Blood and liver samples came from 13 patients with simple steatosis (SS), 15 steatohepatitis (SH) and 21 healthy controls (CO). We found a correlation between plasmatic AST and ALT levels with TLR9 expression in peripheral $CD8^+$ cells ($r=0.645$, $p=0.037$; $r=0.645$, $p=0.034$), and between plasma triglycerides levels with TLR9 expression in hepatic $CD4^+$ cells ($p=0.034$, $r=0.821$) from NAFLD patients. Liver $CD4^+$ cells (p=0,020) and peripheral $CD4^+$ and $CD8^+$ cells ($p=0.022$; $p=0.002$) from SS patients

showed a low TLR9 expression vs. CO. $CD8^+$ cells from SS patients exhibited a low frequency of $CD8^+IFNg^+$ cells (p=0,002 vs SH). A higher frequency of $CD4^+CCR7^-$ cells (p=0.013, vs. CO) was found but unrelated to a higher expression of TLR9 in the $CCR7^+$ and $CCR7^-$ cells. The overall lesser expression of TLR9 and particularly its association with cytotoxic cells differentiation in SS, but not with memory cell generation, might confer protection against NAFLD progression.

Keywords: TLR9, NAFLD, adaptive cells

(1116) **ALPHA-(2,6) SIALYLATION INFLUENCES B CELL FUNCTIONALITY IN THE MUCOSAL COMPARTMENT**

Anabela M. Cutine (1), Luciano G. Morosi (2), Verónica Martinez Allo (2), Rosa Morales (2), Sabrina Gatto (2), Marianela Sasso Ferrer (1), Yamil Mahmoud (3), Maria May (4), María R. Girotti (3), Gabriel A. Rabinovich (2), Marta A. Toscano (2), Karina V. Mariño (1)

Glycosylation is a common post-translational modification that has the potential to regulate cellular processes relevant to immune tolerance and disease. Here, we aim to examine the impact of α(2,6) sialylation (α2,6sia) on B-cell functionality, specifically in the context of intestinal immunity. In a α(2,6) sialyltransferase (ST6Gal1) KO mouse model, we found that the animals exhibited a decreased percentage of IgA+ plasma cells (PCs) in the intestinal lamina propria and alterations in fecal bacterial coating with IgA. Moreover, 16S rRNA gene sequencing analysis of fecal microbiota also showed significant differences in bacterial composition and a reduction in diversity compared to wild type (WT) mice. In order to study α(2,6)sia influence on B-cells during intestinal inflammation, we established a chronic T-cell transfer model of colitis in $RAG2^{-/-}$ mice. Co-transfer of CD4+CD45RBhi T-cells and WT B-cells reduced colonic inflammation and IFN-γ expression in lamina propria (LP). However, co-transference with $ST6Gal1^{-/-}$ B-cells resulted in decreased percentage of B-cells in mesenteric lymph nodes, lower amounts of IgA+ plasma cells and increased number of CD4+ T-cells in LP. Additionally, we observed a decreased percentage of IgA-coated bacteria when compared to co-transference of WT B-cells. These results show an unrecognized role of sialic acid in the mucosal compartment, B-cell functionality and reveal potentially novel mechanistic roles for B-cell glycobiology in intestinal inflammation.

(5) Programa Disciplinario de Inmunología - Facultad de Medicina - Universidad De Chile.

Juvenile polyps are common in paediatric patients, leading to rectal bleeding and diarrhea. The aetiology is largely unknown and we have previously characterized the allergic inflammatory infiltrate of the polyp tissue in children with clinical suspicion of milk allergy. We found high frequency of eosinophils, IgE-producing plasma cells, Th2 cells, high level of type 2 cytokines and augmented expression of ST2 and IL33. These results lead us to investigate the production of thymic stromal lymphopoietin (TSLP) and IL-33 as contributors to the development of the Th2 local immune response.

TSLP and IL-33 expression were assessed in the epithelial compartment and lamina propria of colonic polyps (P) and surrounding colonic tissues (SCT). Biological samples were obtained in 7 patients by colonoscopy and analysis were performed by confocal microscopy and qPCR.

We found a significant increased expression of IL-33 in epithelial cells from P compared with SCT (p<.04), while no expression was observed for TSLP in P and SCT. In contrast, TSLP (p<.07) and IL-33 (p<.05) were increased in the lamina propria of P compared with SCT. Confocal microscopy revealed the presence of $IL33^+$ epithelial cells (11.50±3.96 vs 1.00±0.41 cells in 600x field, P vs SCT respectively) (p<.04). TSLP was not detected in epithelium of P or SCT. In addition, the lamina propria revealed the presence of $TSLP^+$ cells (11.75±2.81 vs 1.50±0.30 cells in 600x field, P vs SCT respectively) (p<.01) and $IL33^+$ cells (27.40±4.02 vs 2.25±0.95 cells in 600x field, P vs SCT respectively) (p<.001).

In conclusion, we found different cell sources of TSLP and IL-33 with a strong production of IL-33 in the epithelial compartment of the inflammatory tissue. These findings may shed light to understand the etiology of the allergic infiltrate found in the inflammatory colonic tissue of patients with food allergy.

(1890) **BLIMP-1: A NEGATIVE REGULATOR OF IFN-g EXPRESSION IN THE IMMUNE RESPONSE TO *Mycobacterium tuberculosis*.**

Martín Andrés Estermann (1), Josefina Celano (1), Angela María Barbero (1), Rodrigo Emanuel Hernandez Del Pino (1), Cristian Doñas Cuadras (2), Mónica Machain (3), Mario Rosemblatt (2), Alejandra Loyola (2), Virginia Pasquinelli (1)

(1) CITNOBA (CONICET-UNNOBA). CIBA. (2) Fundación Ciencia para la Vida. (3) Laboratorio Hospital Interzonal General de Agudos (HIGA), Abraham Piñeyro.

Tuberculosis now ranks alongside with HIV as the leading cause of death from an infectious disease. Protective immunity against *Mycobacterium tuberculosis* (*Mtb*) is mediated by Th1 immune response and IFN-g secretion.

Blimp-1 plays key roles in many cell lineages and in early development, promotes Th2 lineage commitment by opposing the differentiation of IFN-g-secreting Th1 cells. Overexpression of Blimp-1 in T cells attenuates Th1 cell expansion through downregulation of IFN-g.

Therefore, we evaluated Blimp-1 protein expression in PBMCs from healthy donors stimulated with *Mtb* at different time points. We found the highest Blimp-1 expression after 3 days of *Mtb*-stimulation. Blimp-1 expression decreased at 4 days and showed the lowest expression after 5 days of *Mtb*-stimulation. Blimp1 kinetic was opposite to IFN-g; with the highest levels at 5 days of *Mtb* stimulation (as determined by ELISA).

We further studied Blimp-1 expression levels in $CD3^+$ $CD4^+$ T cells by flow cytometry. We observed high levels of Blimp-1 on CD4+ T cells. Moreover, *Mtb*- stimulation decreased Blimp-1 expression after 5 days. Interestingly, Blimp-1 expression among IFN-g producing cells was reduced after 5 days of *Mtb*-stimulation.

Finally, to evaluate if Blimp-1 directly regulates IFN-g expression, we determined Blimp-1 binding to the IFNG gene regulatory sites CNS-22 and -242 by ChIP-qPCR. At CNS-22 site of IFNG gene we found higher binding of Blimp-1 at 3 days of *Mtb*-stimulation compared to 5 days. We did not find binding differences at -242 binding site.

Taken together, our results demonstrate that *Mtb* stimulation regulates Blimp-1 expression on T cells and further suggest that Blimp-1 could act as an IFN-g repressor, trough the binding to CNS-22 site during *Mtb* stimulation.

During the immune response against *Mtb*, IFN-g is regulated by epigenetic modifications. Blimp1 could be responsible to recruit histone modification complex to the IFN-g regulatory sites.

(241) **B CELLS SUSTEIN *Trypanosoma cruzi* SPECIFIC CD8+ T CELL RESPONSE VIA IL-17**

Facundo Fiocca Vernengo, Cristian Gabriel Beccaria, Laura

Almada, Cintia Liliana Araujo Furlan, Jimena Tosello Boari, Carolina Lucia Montes, Eva Virginia Acosta Rodriguez, Adriana Gruppi
CIBICI-CONICET. Fac. de Cs. Químicas, UNC.

CD8+T cells are key in the defense against *T.cruzi* infection. Then, factors that promote the generation and maintenance of CD8+T cell response need to be studied in deep. The aim of our work was to analyze the role of B cells on CD8+T cell response during *T.cruzi* infection.

For this, 8 days before intraperitoneal (ip) infection with 5000 trypomastigotes of *T.cruzi* Tulahuén strain, C57BL/6 mice were ip injected with anti-CD20 (BcD mice), to deplete B cells, or with control isotype. At 20 days post infection (dpi), tissue parasitic DNA quantification was assessed by real time PCR and *T.cruzi*-specific CD8+T cell response was measured by FACS using tetramers loaded with the parasite immunodominant peptide Tskb20. Phenotype and function of CD8+ T cells were also analyzed by FACS.

Infected BcD mice exhibited higher parasitism than controls. Further, infected BcD mice had a significant lower frequency and number of Tskb20+CD8+T cells in blood, spleen and liver (p=0.01), lower frequencies of short-lived (p=0,03) and memory (p=0,02) effector cells, and a significant higher frequency of naïve CD8+T cells, than infected controls. Total and *T.cruzi*-specific CD8+T cells from infected BcD mice exhibited a lesser extent of activation and proliferation but higher levels of inhibitory receptors. In agreement, CD8+T cells from infected BcD mice presented reduced cytotoxicity, degranulation, IFN and TNF production (p=0,02). When infected mice with a settled down specific-CD8+T cell response (12dpi) were depleted from B cells, interestingly, they exhibited the same characteristics than those depleted before infection. Injection of recombinant IL-17 rescued the frequency, phenotype and function of CD8+T cells generated in B cell absence.

Results indicate that B cells are key for *T. cruzi* specific CD8+T cell maintenance and function, but are not necessary for their induction. Considering B cells produce IL-17 in *T. cruzi* infection probably its function on CD8+ T cells depends on IL-17.

Keywords: B cell, CD8 T cell, *T. cruzi*, IL-17

(6) Departamento de Patología Experimental, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.

The ability of Mycobacterium tuberculosis (Mtb) to persist relies on its numerous immune evasion strategies such as the dysregulation of the lipid metabolism leading to foamy macrophages (FM). Although FM provide an environment which is essential for bacilli to escape from host immune system, the specific host factors leading to FM induction are unknown. We aimed to characterize which host factors may contribute to FM differentiation in Mtb infection. For that we use the acellular fraction of tuberculous pleural effusions (PE) as a source of local factors released during *Mtb* infection. We treated human macrophages with PE and evaluated the accumulation of lipid bodies by oil O red staining, cytokines by ELISA, ACAT and pSTAT-3/STAT-3 by western blot, cholesterol by enzymatic assays, CD36 and CD210 by FACS, and bacillary loads by colony-forming units assays.

PE induced FM differentiation as observed by the increased in lipid bodies ($p<0.01$), intracellular cholesterol ($p<0.05$), CD36 expression –receptor which mediates lipids uptake- ($p<0.05$), and ACAT expression –enzyme that esterifies cholesterol- ($p<0.05$). All these parameters could be prevented after IL-10-depletion unlike the depletion of IL-1**β**, IL-6, IFN**γ**, IL-4, or TNFα ($p<0.05$). In line with it, while PE induced the activation of STAT-3 –transcription factor activated by IL-10- ($p<0.05$) and the expression of IL-10 receptor (CD210; $p<0.05$), the inhibition of STAT-3 prevented FM differentiation ($p<0.05$). Interestingly, PE treatment enhanced the bacillary loads in an IL-10 dependent manner ($p<0.01$). To confirm the role of IL-10, we evaluated whether BMDM from IL-10 KO mice could indeed become FM. IL-10 deficiency prevented FM induction after Mtb lipids exposure in comparison with wt BMDM ($p<0.05$). In conclusion our results provide evidence for a role of IL-10 in promoting FM differentiation in the context of Mtb infection contributing to our understanding of the host metabolic alterations driven by Mtb.

(488) PROKARYOTIC RNA MODULATES ENDOTHELIAL-NEUTROPHIL INTERACTIONS

Nahuel Rodriguez-Rodrigues, Luis A. Castillo, Daiana Martire-Greco, Federico Birnberg-Weiss, Veronica I. Landoni, Gabriela C. Fernandez
Instituto de Medicina Experimental (CONICET), Academia Nacional de Medicina. Buenos Aires, Argentina.

Human neutrophils (PMN) are able to sense bacterial viability, activating and generating a response only against live bacterial stimuli. In this regard, we have demonstrated that prokaryotic RNA (pRNA), present only in live bacteria, is capable of triggering PMN activation and the generation of bactericidal responses. Because endothelial cells can actively regulate the migration of PMN through the endothelium by the expression of adhesion molecules and chemokines, our objective was to determine if pRNA can directly activate the endothelium and modulate the interaction with PMN. In all experiments, a microvascular endothelial cell line (HMEC-1) was stimulated with RNA (1 μg/ml) extracted from *E. coli* (pRNA) or from human eukaryotic (mononuclear) cells (eRNA), or left untreated, for 24 hs. After stimulation, the expression of ICAM-1 (CD54) in HMEC-1, measured as the MFI by FACS was increased in pRNA-treated cells compared to the other groups ($p<0.001$). Moreover, the secretion of IL-8 after pRNA exposure was higher ($p <0.05$) measured by ELISA. To determine the effect on PMN, stimulated-HMEC-1 free supernatants were incubated for 30 min with PMN isolated from healthy donors. Both, cell size (% of high FSC) and CD11b expression (MFI) measured by FACS were increased in PMN incubated with cell free supernatants obtained from pRNA-treated HMEC-1 ($p<0.05$). Through the use of a chemotaxis chamber, a significant migration of PMN was observed only when supernatants from HMEC-1 that had been pre-treated with pRNA were used as the chemotactic stimuli ($p<0.05$). We also evaluated the adhesion of PMN to HMEC-1 treated cells, by measuring the activity of PMN alkaline phosphatase with the substrate p-nitrophenylphosphate in the adhered PMN after washing. Higher adhesion was observed only when HMEC-1 were pre-treated with pRNA ($p<0.05$). Our results indicate that the presence of pRNA directly activates the endothelium, which releases signals for the recruitment and adhesion of PMN.

(625) PROSTAGLANDIN E2 INTERFERES WITH TGF-β SIGNALLING IN MONOCYTE-DERIVED DENDRITIC CELLS

Ana Paletta, Melina Gonzalez Prinz, Augusto Varese, Clara Pavillet, Juan Sabatté, Jorge Geffner, Ana Ceballos, Federico Remes Lenicov
INBIRS

Abstract: Monocytes infiltrate infection sites and tumors, where they sense microenvironmental cues and become dendritic cells (DCs) or macrophages that will be key players of the ensuing immune response. TGF-β and prostaglandin E2 (PGE2) are two ubiquitous immunomodulators, known to influence differentiation of DCs. Presence of TGF-β during differentiation of DCs with IL-4 and GM-CSF leads to DCs with enhanced inflammatory properties. Conversely, PGE2 drives differentiation towards generation of myeloid-derived suppressor cells.

In this study we aim to investigate the impact of PGE2 on the profile induced by TGF-β during differentiation of DCs. To this end, we incubated human monocytes for 5 days with IL-4 and GM-CSF alone (control DC) or with TGF-beta (T-DCs), with or without the addition of PGE2 (10-7M) at the beginning of the culture.

Compared to control DCs, T-DCs showed higher CD1a and decreased CD14 expression, as well as enhanced LPS-induced IL-12 production. Notably, LPS-induced expression of IL-10 was completely abolished. However, simultaneous addition of PGE2 led to DCs showing a CD1a-CD14+ phenotype and unable to fully mature or produce IL-12 after LPS stimulation (12 vs 1347 pg/ml in T-DCs). These DCs, which produced higher levels of IL-10 (1410 vs 35 pg/ml in T-DCs) and IDO (22 times more than T-DCs, by qPCR), elicited the expansion of CD25+FoxP3+ T cells when cultured with allogeneic CD4+ lymphocytes (17.9% vs 8.0% in T-DCs). These results indicate that the presence of PGE2 can override TGF-β signaling and drive DCs towards a tolerogenic phenotype. Furthermore, we demonstrated that inhibition of TGF-beta by PGE2 requires prostanoid receptors EP2 and EP4, elevation of cyclinc AMP and PKA activity.

Taken together, these results suggest that potential TGF-β pro-inflammatory actions on myeloid differentiation in the context of tumor or inflammatory microenvironment could be masked by the simultaneous presence of PGE2.

Keywords: inflammation, monocytes, dendritic cells, PGE2, TGF-β

(626) SEMINAL PLASMA INHIBITS SPERM-INDUCED ACTIVATION OF NEUTROPHILS

Melina Gonzalez Prinz, Ana Paletta, Augusto Varese, Jorge Geffner, Ana Ceballos, Federico Remes Lenicov
INBIRS

Semen deposition on the genital mucosa induces an infiltration of neutrophils to the vaginal lumen, where they rapidly outnumber sperm cells. Previous reports have shown that neutrophils interact with sperm cells, but details are lacking regarding the impact of this interaction on their function. This study analyzes the influence of spermatozoa and seminal plasma (SP) on the immune properties of neutrophils, in paticular their ability to modulate dendritic cell (DC) phenotype and thus influence adaptive immunity.

Semen samples from healthy donors were used to obtain SP and spermatozoa (purified by density gradient centrifugation). Neutrophils were purified from blood by Ficoll-Paque centrifugation followed by dextran sedimentation. DC were obtained from monocytes cultured with GM-CSF and IL-4 for 5 days. Neutrophil and DC phenotype were analyzed by flow cytometry and cytokine production was assessed by ELISA.

Incubation of neutrophils with sperm cells led to increased expression of CD11b (MFI 548 +/- 34 vs 1048 +/- 51, n=5), CD66 (MFI 987 +/- 144 vs 1348 +/- 151, n=5), and increased production of IL-6 (pg/ml: 701 +/- 105 vs 387 +/- 51, n=4) and TNF (pg/ml: 1038 +/- 234 vs 617 +/- 42, n=4). Addition of SP in dilution 1:20 inhibited neutrophil phenotypic activation and secretion of cytokines. Interestingly, this result was mimicked by addition of prostaglandin E2 (10^{-6} M), a known inhibitor of neutrophil function that is abundant in SP. In a second set of experiments, neutrophils pre-incubated with SP were co-cultured with DCs. When compared to DCs co-cultured with control neutrophils, DCs co-cultured with SP-treated neutrophils had diminished production of LPS-induced IL-6 (pg/ml: 2456 +/- 344 vs 677 +/- 98, n=3) and IL-1β (pg/ml: 1415 +/- 168 vs 419 +/- 84, n=3).

Taken together, these results indicate that SP can block the sperm-induced activation of neutrophil and also educate them to modulate the function of DCs, suggesting a novel immunoregulatory function of SP.

Keywords: seminal plasma, PGE2, neutrophils, semen, dendritic cell

(675) THE SPLEEN TYROSINE KINASE SYK PARTICIPATES IN THE ACTIVATION OF GAMA DELTA T CELLS BY MONOSODIUM URATE CRYSTALS

Carolina Maiumi Shiromizu, Nadia Yasmín Towstyka, Ana Colado, Irene Keitelman, Florencia Sabbione, Mercedes Borge, Analía Silvina Trevani, Carolina Cristina Jancic
IMEX CONICET - Academia Nacional de Medicina

γδ T cells act as sensors of cellular stress and infection. They recognize danger and pathogen-associated molecular patters, such as phosphoantigens. Uric acid is a cellular stress signal, which is released from dying cells and promotes the generation of innate and adaptive immune responses. The inflammatory effect of uric acid depends on its precipitation into monosodium urate (MSU) crystals. MSU crystals activate different intracellular pathways, i.e. p38 MAPK, Syk kinase and PI3K. We have previously reported that MSU crystals activate γδ T cells and that this activation was reduced in presence of a Syk tyrosine kinase inhibitor. Now, we aim to investigate more in detail the participation of Syk tyrosine kinase during the intracellular signaling triggered by MSU crystals in γδ T cells. To this purpose, γδ T cells were purified from human peripheral blood mononuclear cells by using an anti-TCR γδ MicroBead isolation kit. After purification, γδ T cells were incubated or not with MSU crystals (200 μg/ml) at different time points, and then we analyzed the expression of phospho(p)-Syk (the active form of the tyrosine kinase) by immunofluorescence and confocal microscopy analysis. We observed an increase in p-Syk expression at 5 and 15 min post-stimulation by MSU crystals ($p<0.05$, n= 2), followed by a decrease in the level of expression at 45 min. The maximum values obtained after MSU crystals stimulation were similar to that observed in cells treated with peroxide oxygen (positive control). Our results suggest that, in γδ T cells, MSU crystals induce the activation of the tyrosine kinase Syk pathway.

Key words: γδ T cells, MSU crystals, Syk kinase

(976) RELEVANCE OF PLATELETS IN NETS-INDUCED ENDOTHELIAL DAMAGE IN HEMOLYTIC UREMIC SYNDROME.

Verónica Inés Landoni, Nahuel Rodriguez-Rodrigues, Luis Alejandro Castillo, Agostina Carestia, Marcelo de Campos Nebel, Daiana Martire-Greco, Federico Birnberg Weiss, Mirta Schattner, Pablo Schierloh, Gabriela Cristina Fernández
IMEX-CONICET/ANM

Hemolytic Uremic Syndrome (HUS) is the most common cause of pediatric renal failure. Linked to Gram (-) Shiga toxin-producing (Stx) infections, lipopolysaccharide (LPS) and neutrophils (PMN) can potentiate the disease. Since endothelial damage is characteristic of HUS, PMN-platelet (Plts) interaction in the context of Stx could promote netosis causing endothelial damage. We have shown that Stx2 increases netosis induced by LPS-treated Plts and endothelial cytotoxicity in vitro. The aim of this work is to study in detail this phenomenon and determine the relevance of netosis in a murine model of HUS. We determined in vitro by FACS that Stx2 stimulation of LPS-treated Plts increased the formation of PMN-Plts mixed aggregates (% CD11b+CD61+ p≤0,05) and increased the activation of both PMN (CD11b p≤0,05) and Plts (P-selectin p≤0,05). Additionally, the increased netosis promoted by Stx2 stimulation of LPS-treated Plts was dependent on the PMN-Plts-mediated P-selectin junction. In order to corroborate in vitro findings, mice administrated with LPS and Stx2 showed an increased % of PMN-Plts blood aggregates (%Gr1+CD61+ p≤0.05) in LPS+Stx2 treated mice. Also the NETs in this group were increased measured using an ELISA kit (PMN Elastase-DNA levels p≤0.05).Correlating with this, endothelial damage was higher in LPS+Stx2 treated mice (von Willebrand Factor, vWF levels in plasma p≤0.05). NETs were digested and levels of Elastase-DNA decreased correlating with vWF diminution. Finally, in order to evaluate the role of circulating Plts mice were depleted of Plts. We observed in LPS+Stx2 mice without Plts that, both netosis (Elastase-DNA levels p≤0.05) and endothelial damage levels (vWF

p≤0.05) decreased compared to LPS+Stx2. These results demonstrate the relevance of LPS+Stx2 induced netosis on vascular damage and the fundamental role of Plts in this phenomenon.

Key-words: HUS, platelets, NETs, endothelial damage.

(1002) **ROLE OF ALPHA-GLUCANS FROM *Mycobacterium tuberculosis* IN DENDRITIC CELL MATURATION AND PHAGOCYTOSIS**

Alejandra Duarte, Daniela Montagna, Mercedes Alemán
IMEX-CONICET-ANM

Tuberculosis remains the single largest infectious disease with two million deaths estimated to occur yearly. The spread of *Mycobacterium tuberculosis (Mtb)* from the lungs to other sites occur before the development of adaptive immune responses. The major carbohydrate constituents from *Mtb* surface are α-glucans, a sugar which has been implicated in fungal virulence, and represent up to 80% of the extracellular polysaccharides in Mycobacteria. Previous results demonstrated that reactive oxygen species (ROS) in neutrophils are generated by non-opsonized mycobacteria through α-glucans and that the lack of a-glucans in *Mtb* leads to the loss of their ability to induce ROS and also dendritic cell (DC) maturation and antigen presentation. Here we evaluated the role of α-glucans in the entrance of bacteria in DC and the endogenous production of ROS as effectors of the maturation of DC. Results Monocyte-derived DC were incubated 24 hours with LPS and thereafter were treated with *Mtb* (H37Rv) subjected or not to a-amyloglucosidase treatment (*Mtb-e*) for 15 min with or without H2O2. Thereafter maturation markers were evaluated by cytometry. Expression of CD86 ($p<0.001$) and MHC-II ($p<0.01$) were induced by *Mtb* but significantly less induced by *Mtb-e* ($p<0.001$) whereas treatment with H2O2 restored parameters of maturation ($p<0.05$). In addition, LPS primed DC were incubated with 123Dihidrorhodamine (123DHR) treated *Mtb* and thereafter emission of oxidized DHR was evaluated by flow cytometry as a measure of phagocytosis. Whereas *Mtb* induced significant ROS production ($p<0.002$), *Mtb-e* induced less but significant signal ($p<0.002$). Conclusion Here we show that lack of the ability to induce DC maturation by a-glucans in *Mtb* is due to the loss of their ability to induce ROS. In addition, a-glucans in *Mtb* participate in entrance to DC being essential for the onset of the protective immune response because maturation and function of DC are critical against tuberculosis disease.

Key Words: tuberculosis, dendritic cell, alpha-glucans

(1372) ***Tc*13Tul ANTIGEN FROM *Trypanosoma cruzi* INDUCES B-CELL PROLIFERATION IN SPLENOCYTES FROM *NAIVE* BALB/C MICE**

Laura Mónica Tasso, Andrea Bruballa, Patricia Garavaglia, Mónica Esteva, Cecilia Albareda, Gabriela García
Instituto Nacional de Parasitología "Dr. Mario Fatala Chabén" - ANLIS "Dr. Carlos G. Malbrán"

Several soluble factors of *Trypanosoma cruzi*, the ethiological agent of Chagas´ disease, modulate host immune responses, among them the enzyme trans-sialidase (*Tc*TS), a member of group I of the trans-sialidase superfamily (TS). Here, we evaluated the effect of *Tc*13Tul antigen on splenocytes from *naive* BALB/c mice. *Tc*13Tul belongs to group IV of TSs, characterized by C-terminal EPKSA repeats.

Splenocyte proliferation were assessed by CFSE staining after 72 h of incubation with recombinant *Tc*13Tul, EPKSA repeats or the carrier protein MBP as a control. Flow cytometry analysis showed an increase in the % of divided cells when incubated with *Tc*13Tul (11.65 ± 0.07 % vs. 0.93 ± 0.12 % for EPKSA or 1.29 ± 0.05 % for MBP; $p<0.001$). *Tc*13Tul induced B-cell (CD19+) proliferation (12.9 ± 0.28 % vs. 1.50 ± 0.34 % for MBP, $p<0.0001$). Conversely, no differences were observed in the % of divided T-cells (CD3+) respect to MBP. Stimulation with *Tc*13Tul also resulted in an increased IgG secretion (16.26 ± 5.21 µg/ml vs. 3.57 ± 1.84 µg/ml for MBP; $p<0.05$). However, no IL-17 was produced as it has been reported for *Tc*TS.

*Tc*13Tul also induced B-cell proliferation and IgG secretion in *naive* splenocytes from the mouse strain C3H/HeJ, deficient in the LPS receptor, confirming that these effects are due to *Tc*13Tul and not to LPS in the antigen preparation.

Splenocyte-antigen interaction assays using FITC conjugated proteins showed 2.6-fold higher labeling in lymphocyte population with *Tc*13Tul-FITC than with MBP-FITC. *Tc*13Tul-FITC bound to 96.06 % of CD19+ and 78.73 % of CD3+ populations, while the control protein MBP-FITC bound to 34.6 % and 11.1 % of CD19+ and CD3+ cells, respectively. Therefore, these results suggest that *Tc*13Tul may interact with surface antigens on both B and T cells.

Our results indicate that *Tc*13Tul antigen may participate in the innate immunity against *T. cruzi* by favoring immune system evasion through B-cell activation and non-specific IgG secretion.

Keywords: Chagas´disease, innate immune response, lymphocyte.

(1802) **AUTOPHAGY IS REQUIRED FOR THE *TRYPANOSOMA CRUZI* ELIMINATION IN MACROPHAGES BY XENOPHAGY**

María Cristina Vanrell, Ana Florencia Casassa, Patricia Silvia Romano
IHEM-Conicet-UNCuyo

Trypanosoma cruzi is the etiologic agent of Chagas, an endemic disease of Latin-American countries. Autophagy is a cellular process required for the removal of aged organelles and cytosolic components through lysosomal degradation. In previous studies, we observed that mice deficient in autophagy displayed a more aggressive infection indicating that this process could be participating as a component of the immune response against the parasite. The main objective of this work was the study the participation of xenophagy in the elimination of *T. cruzi* in macrophages. Xenophagy is a specialized type of autophagy responsible for the capture and elimination of intracellular microorganisms in macrophages. To study this process we detect specific xenophagic-related proteins in peritoneal cells obtained from C57wt mice and C57 Beclin-1 +/- mutant mice (deficient in autophagy) that was previously infected with trypomastigotes of *T. cruzi* Y strain. We also infected Raw cells under different conditions of autophagy inhibition. Data showed that infected macrophages displayed higher levels of LC3 expression compared with non-infected cells. This LC3 was recruited surround the parasitic bodies in the cell cytoplasm. We also observed that when autophagy is inhibited, the number of amastigotes per cell increased. Other proteins involved in xenophagy were found decorating the parasites. We conclude that the autophagic pathway is participating in the elimination of intracellular amastigotes in macrophages by xenophagy.

Key words: Autophagy, Xenophagy, *Trypanosoma cruzi*, macrophages.

(1873) **THE BACULOVIRUS ACMNPV INDUCES THE PRODUCTION OF INTERFERONS IN THE PORCINE MODEL**

Guido Nicolás Molina, Sabrina Amalfi, Oscar Taboga, Paula Molinari
Instituto de Biotecnología, INTA Castelar.

Baculoviruses (BVs) are dsDNA viruses that infect insects and belong to the *Baculoviridae* family. The model species *Autographa californica nucleopolyhedrovirus* (AcMNPV) is able to transduce mammalian cells, but not to replicate, and to induce a strong innate immune response. Because of the high frequency of CpG motifs present in its genome, they stimulate the production of inflammatory cytokines and type I and II interferons (IFNs) via the Toll-like receptor 9 (TLR9)/MyD88-dependent signaling pathway in mice. However, there are cytosolic DNA sensing pathways involved in the IFNs induction in some cells. Mice inoculated with BVs were protected at short term against challenges with influenza H1N1, encephalomyocaditis virus and foot and mouth disease virus. There are not studies about the effects of the BVs in the porcine innate immune response.

The aim of this work is to evaluate if the BV AcMNPV is able to induce the production of IFNs in swine peripheral blood mononuclear cells (PBMCs), macrophages and the epithelial cell line of kidney PK15. Each cell type was infected with different multiplicities of infection of BVs. After 16 hours, the supernatants were collected and the presence of IFNs was determined by a bioassay in MDBK

cells based on their antiviral effect against vesicular stomatitis virus (VSV) infections. The specific presence of IFN-alpha in supernatants was detected by ELISA. The BV was able to promote the production of IFNs in the supernatants of all the cell types studied ($p \leq 0.01$), and quantities of IFN-alpha were detected in supernatants of PBMCs ($p \leq 0.01$).

In conclusion, AcMNPV induces the production of high levels of IFNs in porcine cells and the specific presence of IFN-alpha could be identified. Therefore, this work showed that BVs are a potential tool that deserves to be studied for the development of antiviral strategies in pigs.

(080) **BRAIN DISTRIBUTION OF IMMUNOREACTIVE NEURONS AND FIBERS EXPRESSING GnIH IN PEJERREY, Odontesthes bonariensis.**

Ana María Pahí-Rosero (1), María Rita Pérez (1), Gabriela Carina López (1), Paula Gabriela Vissio (2), Gustavo Manuel Somoza (1)
(1) IIB-INTECH (CONICET-UNSAM). (2) DBBE (FCEyN, UBA).

Gonadotrophin-inhibitory hormone (GnIH) is a RFamide peptide, originally characterized in the japanese quail as an inhibitor of gonadotropins, changing the classical view of the regulation of vertebrate reproduction. Later, it was also found in others vertebrate species, with similar function. However, the effects in fish remain controversial. In this context, as a first step, the objective of this work was characterized the neuroanatomic distribution of GnIH neurons and fibers in the brain of adult pejerrey by immunohistochemistry. Our results showed that neuronal somata with immunoreactivity to GnIH (ir-GnIH) were localized at the olfactory bulbs, the junction of the olfactory bulbs and telencephalon (Terminal Nerve Ganglion or *Nucleus Olfacto Retinalis*) and the *Nucleus Posterioris Periventricularis* (NPPv). This distribution was similar to that reported in other teleost fish species. Moreover, some isolated neuronal somata were detected in the *Nucleus Paraventricularis Posterioris* (NPP) in the preoptic area (POA). While ir-GnIH fibres were present in all brain areas examined, and also at the pituitary gland. In addition, double labelling with GnIH and GnRH I (also known as pjGnRH) antisera was performed, in order to analyze a possible relationship between GnIH and the hypophysiotropic GnRH variant of this species. In double labelling immunocytochemistry, ir-GnIH fibers were localized very close to ir-GnRH neurons in the preoptic area, suggesting that both neurons could interact. This is the report on the GnIH distribution in the brain of pejerrey and its relation with GnRH.

(1732) **COMPARATIVE MORPHOLOGICAL STUDY OF BRISTLES ON CATERPILLARS WITH MEDICAL RELEVANCE IN MISIONES.**

Milena G. Casafús, Matías N. Sánchez (1,2), Adriana I. Zapata (3), María M. Matínez (1), Danny A. Soto (1), Ana T. Bittencourt Guimarães (4), Ma. Elisa Peichoto (1,2)

Caterpillars (larval stage of butterflies and moths) have urticating bristles which protect them from predators and are also responsible for the cutaneous reactions observed when human beings inadvertently lean against them. In recent years, accidents caused by different species of caterpillars have become more common among people living in Misiones. Taking into account that the biology of these animals remains to be poorly understood, we conducted a morphological study of the urticating bristles in representatives of the two families that are most frequently involved in accidents in this province: Saturniidae (*Automeris naranja, Hylesia nigricans, Leucanella memusae, Lonomia obliqua*) and Megalopygidae (*Megalopyge lanata, Podalia orsilochus and Podalia* aff. *fuscescens*). The external morphology of the caterpillars (scoli and spines) was observed and photographed under a stereomicroscope. The median dorsal region of caterpillar bodies were dissected and isolated, cleaned, critical-point dried, coated with a thin layer of gold, and finally examined by scanning electron microscopy. In this study, all caterpillars exhibited scoli with spines that bear a hollow canal. In *L. obliqua*, we could observe some spines that possessed a circular groove similar to a ring-like structure, and other spines that lacked this groove. The latter were the only type of spines that we could observe in *A. naranja, H. nigrincans and L. memusae*. The scoli of *P. orsilochus*, *P.* aff. *fuscescens* and *M. lanata* exhibited similar structures, showing long hairs with transverse striations and spicules, and short and hollow spines. It is noticeable that the saturnid *H. nigricans* also exhibited long hairs with spicules. Altogether, this is the first comparative morphological study showing the way in which different species of Argentinian caterpillars can induce an irritant or toxic dermatitis in humans.

Key words: caterpillars, urticating bristles, Saturniidae, Megalopygidae.

(1864) **COMPARATIVE ONTOGENY OF THE TEGUMENTARY SYSTEM OF RHINELLA SCHNEIDERI (ANURA: BUFONIDAE), *LEPTODACTYLUS CHAQUENSIS* (ANURA: LEPTODACTYLIDAE) AND *SCINAX ACUMINATUS* (ANURA: SCINAXIDAE)**

Profound changes and complexation of anurans tegument accompany morphological, physiological and behavioral modifications that take place during metamorphosis. Also, its structure allows interpreting specific biological characteristics of the habitat of each species. The objective of this work was to analyze comparatively the external morphology and histology of the tegument during the ontogeny of *Rhinella schneideri* (Rs), *Leptodactylus chaquensis* (Lc) and *Scinax acuminatus* (Sc). Larval, juvenile and adult specimens of the species were analyzed in stereoscopic magnifying glass and scanning electron microscopy (SEM) to establish macro-structural comparisons. Histological sections were obtained by a conventional technique and were stained with H&E, Mallory Trichrome, and PAS for contrast tissue aspects. The three species coincided in general tegument configuration (epidermis and dermis), and its changes that go through ontogeny. Significant differences were found in presence and time of appearance of specialized structures. Giant cells associated with gregarious behavior were recorded at different larval stages for Rs and Ls. Multicellular glandular outlines appeared in pro-metamorphosis for Rs and Sa, but just in the metamorphic climax for Lc. Tubercles and spines were described for Rs, pustules and minor protuberances for Sa and a smooth tegument without macroscopic specializations for Lc. The mucosal glandular content match the serous one in Lc, while the others two species had higher serous contents. That agrees with the habitat of each species, mostly associated with water bodies and terrestrial surroundings, respectively. This work will serve as a basis for future comparative studies with other anurans and for ecomorphological analyses that will deepen in the relationship between the skin properties, the way of life and habitat of species.

Key words: integument, anurans, metamorphosis, glands

(1819) **COMPARATIVE STUDY OF PRENATAL DEVELOPMENT BETWEEN *Myotis albescens* (Chiroptera: Vespertilionidae) AND *Eumops patagonicus* (Chiroptera: Molossidae).**

Florencia Evelyn Rodriguez (1), Maria Teresa Sandoval (1), Blanca Beatriz Alvarez (1), Daniel Marcelo Lombardo (2)
(1) Universidad Nacional del Nordeste. Facultad de Ciencias Exactas y Naturales y Agrimensura. Argentina. Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET).

(2) Universidad de Buenos Aires, Facultad de Ciencias Veterinarias, Instituto de Investigación y Tecnología en Reproducción Animal (INITRA).

The order Chiroptera comprises two suborders, Megachiroptera and Microchiroptera, the Microchiroptera is cosmopolitan, within the order, exist a great diversity of study about reproductive biology. Notwithstanding, there is still important information gaps respect to different aspects of the embryonic development of bats, The staging system proposed for *Carollia perspicillata* is, the most complete and includes the embryo sequence from fertilization until the end of development, and is used as a reference table. Moreover, the characteristics of chorionic vesicle have not been considered in previous studies. The present study aimed to characterize the embryonic development of *Myotis albacescens* and *Eumops patagonicus*, two Center and South American species, widely and commonly distributed in northern Argentina.This study was realized using 60 specimens obtaining of wildlife. There are measured and photographed, and the embryonic stage was assigned what the staging system created for *Carollia perspicillata*. We observed that the chorionic vesicle, in both, showed similarities in the disposition of the extraembryonic membranes, but they differed in characteristics of yolk sac and chorioallantoic placenta, in *E. patagonicus* was more glandular than *M. albescens*. *M. albescens* presented a discoid placenta well developed with the caudal anti-mesometrial position, but *E. patagonicus* presented a diffuse placenta which persists until the final stages of gestation and a discoid placenta in the uterus tubal junction. Respect to the embryogenesis was recognized, in both, early stages (ES), middle stages (MS) and late stages (IS). In the ES, the embryonic morphology is similar. The MS is characterized by the muzzle and pinna formation, fore and hind limb regionalization, and the formation of the patagium primordium. In the IS, occur the overall growth of the embryo, of its fore and hind limbs, patagium, and the typical craniofacial features of each species are configured.

Keywords: South American bat; Chiroptera; Vespertilionidae; Molossidae; embryogenesis; chorionic vesicle

(055) **GHRELIN AND NUCB2/NESFATIN-1: CO-LOCALIZATION IN BRAIN AND INTESTINE, POSSIBLE INTERACTION WITH DIGESTIVE ENZYMES IN THE INTESTINE OF PEJERREY (*Odontesthes bonariensis*).**

Juan Ignacio Bertucci (1), Ayelen Melisa Blanco Imperiali (2), Aída Sánchez-Bretaño (3), Suraj Unniappan (4), Luis Fabián Canosa (1)

(3) Department of Pharmacology and Toxicology, and Neuroscience Institute, Morehouse School of Medicine, Atlanta, GA, United States. (4) Laboratory of Integrative Neuroendocrinology, Department of Veterinary Biomedical Sciences, Western College of Veterinary Medicine, University of Saskatchewan, Saskatoon.

Abstract: Ghrelin and nesfatin-1 are two metabolic peptides with opposing actions on food intake regulation. Ghrelin is a potent orexigenic, mainly synthesized in the gastro-intestinal (GI) tract of vertebrates, although is also present in central nervous system. Nesfatin-1 is an anorexigenic peptide, mainly synthesized in the hypothalamus although it gene expression was reported in the GI tract. The aim of this work was to characterize by immunohistochemistry the localization of ghrelin and nesfatin-1 in brain and intestine of pejerrey (*Odontesthes bonariensis*), a species with commercial importance in South America. Additionally, the co-localization of both peptides with enzymes involved in the digestion process such as lipoprotein lipase, aminopeptidase A, trypsin and sucrase-isomaltase in the intestine of pejerrey was studied. Results show that both ghrelin and nesfatin-1 have a similar anatomical distribution in brain, with the highest immunoreactivity detected in some hypothalamic nuclei (such as the preoptic nucleus and the posterior recess nucleus) and in the pineal gland, and lower levels observed in telencephalon, optic tectum, cerebellum and some hindbrain nuclei. Both peptides are presents and co-localize in some cells from the mucosa and submucosa layers of pejerrey intestine. Co-localization of ghrelin and nesfatin-1 with lipoprotein lipase, aminopeptidase A, trypsin and sucrase-isomaltase was found in intestine, in cells from the brush border and from the deep part of the mucosa and in the submucosa. In conclusion, in this work we present evidence for the presence and co-localization of ghrelin and nesfatin-1 in brain areas and intestine of pejerrey, which supports the role of both peptides in the food intake regulation. Additionally, the co-localization of ghrelin or nesfatin-1 with digestive enzymes suggests a role for both peptides on nutrient assimilation in pejerrey.

Keywords: digestive enzymes, food intake, ghrelin, nesfatin-1.

(299) **MALE REPRODUCTIVE SYSTEM OF THE "RED CHERRY SHRIMP" *NEOCARIDINA DAVIDI* (CARIDEA)**

Ana Laura Tomas (1), Maria Alice Garcia Bento (2), Fernando Zara (2), Laura Susana López Greco (1)

(1) Departamento de Biodiversidad y Biología Experimental, Laboratorio de Biología de la Reproducción y el Crecimiento de Crustáceos Decápodos, FCEN, UBA e IBBEA, CONICET-UBA. (2) Departamento de Biologia Aplicada, Invertebrate Morphology Laboratory (IML) and Aquaculture Center (CAUNESP), Universidade Estadual Paulista (UNESP).

Caridea is a diverse taxon of marine, freshwater and brackish shrimps poorly studied as far as their reproductive anatomy. This study aimed to describe for the first time the functional anatomy of the male reproductive system in an Atyidae, *Neocaridina davidi, a* very popular ornamental species. For this purpose mature males were cold-anaesthetized and their reproductive systems were dissected for routine histological and histochemical tests. Male reproductive system consists of two coiled testes continuous to the vasa deferentia opening in the gonopores located in the coxae of the fifth pair of pereiopods. Testes are positioned on the dorsal side of the cephalothorax, above the hepatopancreas and below the heart. Testes comprise seminiferous tubules where spermatogenesis occurs. Each vas deferens (VD) is a long tube *dorsolaterally* positioned with respect to the *hepatopancreas,* and divided in proximal, middle and distal zones. The proximal part has a cylindrical epithelium with secretory cells while in the proximal to medial zone the vas deferens has a dorsal fold with high columnar epithelium with secretory activity, the typhlosole. This typhlosole is similar to that observed in *Macrobrachium rosembergii,* yet different from those in penaeid shrimps. The VD increases in diameter distally and the spermatophore (SPF) formation begins at the proximal part of VD. The SPF is a continuous cord with two acellular layers: the inner is thicker with high protein content, and the outermost is much thinner with low protein content, and strongly reactive to the PAS staining. The spermatozoa are arranged in clusters of 3-4 spermatozoa and immersed in an eosinophilic, and strongly PAS positive secretion. Spermatozoa have many spikes. Although further analyses are necessary, the composition of the spermatophore, and the arrangement and form of the spermatozoa appear to be novelties within Caridea. UBACYT-2014-2017-20020130100186BA,PIP-2015-2017-11220150100544, PICT 2016-0759.

Keywords: *Neocaridina davidi,* male reproductive system, spermatophore, testes, vasa deferentia.

(300) **STUDY OF SILYMARIN ACTIVITY ON BRAIN MICROSOMES AND MITOCHONDRIA**

Patricio Jose Leaden, Viviana Piergiacomi, Monica Marmunti, Javier Barberon, Pedro Zeinsteger, Alejandro Palacios

Cátedra de Bioquímica - Facultad de Ciencias Veterinarias, Universidad Nacional de La Plata.

Production of reactive oxygen species can damage cell membranes by forming free radicals, involved in tissue diseases associated with aging processes. Antioxidant activity is the ability of a substance to inhibit oxidative degradation by reacting with free radicals. Vegetables are a source of natural antioxidants: vitamin E, vitamin C, carotenoids. The silymarin (SM) present in the seeds of the Thistle Asnal, is a known liver protector that possesses *Silybum marianum L.* (Gaertner). SM (silymarine phosphatide 16%) used in this work was kindly supplied by Vetanco Laboratories S.A.

In previous studies its antioxidant capacity on liver membranes was observed. The objective of this work was to analyze the in vitro antioxidant activity of SM on the peroxidation of microsomes and brain mitochondria of Wistar rats AH / HOK. Ascorbate-Fe^{++} -dependent non-enzymatic peroxidation assays were performed by incubating 1 mg of protein samples in 0.05 M phosphate buffer, pH 7.4 at 37 ° C. Peroxidation was initiated with ascorbate (final concentration 0.4 mM). Controls without ascorbate were used. The light emission for 180 min was quantified as counts per minute (cpm) every 10 min in a Packard 1900 TR, (Meriden, CT, USA) chemiluminescence program. To study the effect of SM, different concentrations of the product were used: 6.25; 12.5; and 25 µg per mg of mitochondrial and microsomal protein. In the peroxidation assays the protection against oxidative damage in both membranes was SM concentration dependent. Inhibition percentages were in microsomes 31.27%, 51.62% and 71.27%, and in mitochondria 27.99%, 52.92% and 63.76% with respect to the control. These results shown that SM may act as an antioxidant protecting rat brain microsomes and mitochondria from oxidative damage.

(433) **PROTEASOME INHIBITORS IMPROVE TREACHER COLLINS SYNDROME (TCS) IN A ZEBRAFISH (*Danio rerio*) MODEL.**

Gabriela Coux, Agustín Lorenzatti, Mauco Gil Rosas, Nora B. Calcaterra
IBR (CONICET/IBR)

TCS is a congenital disease characterized by defects in the craniofacial skeleton and absence of mental alterations. We modeled TCS in *D. rerio* embryos through the microinjection of Morpholino oligonucleotides blocking the translation of the ortholog of the causative gene (*TCOF1*). Cnbp, a protein required for proper craniofacial development, was detected in lower levels (without changes in its mRNA expression) in TCS-like embryos. As Cnbp degradation is carried out through the proteasomal pathway, we tested if proteasome inhibitors (MG132 and Bortezomib) were able to ameliorate cranial skeleton malformations in TCS.

Two-cell embryos were injected with control Morpholino (C) or *tcof1* translation blocking Morpholino (TC). At 6 hours post fertilization (hpf) embryos were exposed to MG132 (5 μM), Bortezomib (0.5 μM) or vehicle for 18 hours. Cnbp protein level was measured by western-blot in total extracts from 24 hpf specimens. Cranial cartilages measurements were performed in 4 days post-fertilization larvae stained with Alcian Blue by using the ImageJ software. Embryo viability was not affected by any treatment. Control injected embryos did not show any effect on cranial cartilages induced by MG132, Bortezomib or vehicle and were pooled together as control group (C). In arbitrary units, Meckel length: C:100.0 ±0.7, TC: 89.3±3.1*, TC+Bort: 98.7266±2.0, TC+MG132: 91.5795±2.8, Ceratohyal angle: C: 99.4±1.3, TC: 157.3±14.9*, TC+Bort: 103.0±4.6, TC+MG132: 124.3±10.7, $p<0.05$ vs. C, ANOVA. All the craniofacial parameters measured behaved similarly. The results suggest that both drugs (especially Bortezomib) partially rescued the phenotype. Cnbp protein recovered under both treatments although not to control levels.

Data suggest that proteasome inhibitors improve TCS in the zebrafish model, likely by preventing Cnbp protein proteasome degradation. This finding may have potential therapeutic implications for TCS management.

Keywords: proteasome inhibitors, therapy, zebrafish, mandibulofacial dysostosis

(1474) **SURFACE ULTRASTRUCTURE OF THE SCOLEX AND HISTOCHEMISTRY OF THE GLANDULOMUSCULAR ORGAN IN *Orygmatobothrium schmitti* (CESTODA: PHYLLOBOTHRIIDEA)**

Leonardo Damián Mutti, Verónica Adriana Ivanov
Universidad de Buenos Aires. Consejo Nacional de Investigaciones Científicas y Técnicas. Instituto de Biodiversidad y Biología Experimental y Aplicada (IBBEA) Facultad de Ciencias Exactas y Naturales, Departamento de Biodiversidad y Biología Experimental. Buenos Aires, Argentina

Cestodes are parasites of the intestinal tract of vertebrates. Attachment organs in the scolex are used to maintain their position on the intestinal wall of their hosts. *Orygmatobothrium schmitti* (Cestoda: Phyllobothriidea) is a parasite of the shark *Mustelus schmitti* (Chondrichthyes). It possesses a scolex with four bothridia, each having an apical sucker, and a central glandulomuscular organ. The objective of the present study was to describe the microtriches, glandulomuscular organ, subtegumental musculature of bothridium, sensory organs ultrastructure and the histochemical composition of the secretion of the glandulomuscular organ of *O. schmitti*. Seventeen scolices were stained with four histochemical techniques: coomassie brilliant blue, periodic acid-Schiff, toluidine blue and sudan black. Five worms were observed with scanning and transmission electron microscopy. The glandulomuscular nature of the central bothridial organ is confirmed and its ultrastructure is described in detail. Also the internal structure of the tegumental microtriches, two types of sensory organs and subtegumental muscular papillae are described for the first time. The glycoproteic nature of the secretion of the glandulomuscular organ and the apocrine mechanism of secretion are determined. All the microtriches on the apical sucker possess a more developed cap than filitriches on the bothridia, the scolex proper and the cephalic peduncle. These specializations of the scolex might be involved in adhesion and abrasion to the intestinal mucosa of the shark. The microtriches with developed caps could be involved in the attachment to the mucosa, whereas those small caps might be related to the absorption of nutrients.

Keywords: Orygmatobothrium schmitti, cestoda, scolex, glandulomuscular organ, ultrastructure.

(1489) **SURFACE ULTRASTRUCTURE AND HISTOCHEMISTRY OF THE SCOLEX GLANDS OF *Clestobothrium cristinae* (CESTODA: BOTHRIOCEPHALIDEA) PARASITE OF *Merluccius hubssi* (TELEOSTEI)**

Leonardo Damián Mutti, Verónica Adriana Ivanov
Universidad de Buenos Aires. Consejo Nacional de Investigaciones Científicas y Técnicas. Instituto de Biodiversidad y Biología Experimental y Aplicada (IBBEA) Facultad de Ciencias Exactas y Naturales, Departamento de Biodiversidad y Biología Experimental. Buenos Aires, Argentina

Clestobothrium cristinae (Cestoda: Bothriocephalidea) is an intestinal parasite of the hake *Merluccius hubssi* (Teleostei).The scolex of the tapeworms is the principal attachment organ. In *C. cristinae* it possesses an apical disk and two bothria. It is covered with capilliform filitriches and gladiate spinitriches, and possesses tumuli (frontal glands type I) in the proximal bothrial surface. In this study the internal morphology of all these structures and the nature of the secretions of the glands in the scolex are described for the first time in *Clestobothrium*. Ten scolices were stained with several histochemical techniques: coomassie brilliant blue, periodic acid-Schiff and toluidine blue. One worm was analyzed using conventional techniques for transmission electron microscopy. As a result, the internal ultrastructure of the tumuli, and the internal structure of gladiate spinitriches in this genus are described. Groups of cells PAS positive were observed in the same area where the tumuli were described using SEM. It is possible that these groups of gland cells are in fact a constitutive part of the so called tumuli; however, the internal structure is different from the tumuli described in other genera of bothriocephalideans. The secretion is based on mucopolysaccharide, which might indicate they are involved in the adhesion to the intestinal mucosa of the hake.

Keywords: *Clestobothrium cristinae*, cestoda, scolex, *Merluccius hubbsi*, ultrastructure.

Diabetes mellitus is a chronic disease that represents a major problem for the countries health systems. Thus the search of new alternative treatments is constant. Numerous studies indicate that 85% of world population still uses “medicinal plants” to treat its health. *Oxalis erythrorhiza* (Oe) and *Tessaria absinthioides* (Ta) are two species that growth in Argentine, in Cuyo region, and are consumed to regulate the glucose (Glu) and cholesterol (Chol) levels, even when their effects lack of scientific support. On the other hand, the liver X receptors (LXRα and LXRβ) are related with the systemic Chol clearance and the Glu metabolism in the hypothalamus (HT). Forty two days old male rats (SD), diabetics (Ed, i.p. STZ 30mg/Kg) or controls (C, i.p. vehicle) received (5 or 10% W/V) decoctions (Dcs) of Oe (EdOe and COe) or Ta (EdTa and CTa), or water (EdW and CW) as drink for 4 weeks. Glu, Chol and triglycerides (TG) were determined on weekly obtained blood samples by colorimetric kits. LXRs expression was evaluated by WB in HT. At the end of the treatment, the Glu level was lower in EdOe and EdTa (both at 10% W/V) compared to DW (36% and 37% respectively; $p<0.05$), but higher than CW (147% and 305% respectively; $p<0.05$). No significant effects were observed in Chol and TG in these groups. However, Ta 5%W/V significant reduced the LXRα expression in EdTa compared to EdW (64%; $p<0.05$) but still was higher than CW. On the other hand, in Ed groups, Oe (10%) and Ta (5% and 10%) reduced LXRβ expression compared to W (20%, 11% and 18% respectively; $p<0.05$), and also the values were higher than CW group. The Dcs did not produce any effect on the parameters evaluated into the C group. Thereby, Oe and Ta could have regulatory effects on Glu and LXRs expression. Therefore, a more extended treatment will be necessary to achive the research objective and to propose these native plants like new therapeutic tools. (PIP 0243, PIO-SECITI 2250, CICITCA UNSJ, CONICET).

Keywords: diabetes mellitus, hypoglycemic, LXR receptor, phytomedicine.

(789) **ALTERATIONS IN VASCULAR INTEGRITY AND NEURONAL FUNCTIONALITY RELATED TO EARLY STAGES OF DIABETIC RETINOPATHY IN A METABOLIC SYNDROME MOUSE MODEL**

María Constanza Paz (1), Pablo Federico Barcelona (1), Paula Virginia Subirada (1), Magalí Évelyn Ridano (1), Claudia Castro (2), Gustavo Alberto Chiabrando (1), María Cecilia Sánchez (1)

(1) CIBICI-CONICET-UNC, (2) IMBECU-CONICET-UNCuyo.

Diabetic retinopathy (DR) is the most serious ocular complication associated with Type 2 Diabetes Mellitus (T2DM), which is a metabolic syndrome (MS), and one of the leading causes of blindness. Thus, we proposed to analyze in a MS mouse model, markers of retinal vascular integrity and neuronal functionality, related to early stages of DR.

We used C57BL/6 (WT) and Apolipoprotein E knockout (ApoE-KO) mice either fed with a normal diet (ND) or a 10% w/v fructose diet (FD) in drinking water from 2 months of age. We demonstrated ApoE-KO after 2 month of FD, presented hypercholesterolemia, hypertriglyceridemia, hyperglycemia and hyperinsulinemia. Here, retinal functionality was assessed by scotopic ERG at 4 month of FD treatment. Extravasation of serum proteins and levels of proteins involved in neuro-glial injury were analyzed by WB. Vascular permeability was evaluated by albumin–Evans blue complex leakage and astrocyte GFAP levels on whole mounts of retina.

The ERG a-wave and the OPs amplitudes were significantly decreased in retinas of ApoE-KO after 4 month of FD vs WT DN ($p<0.05$), correlating with an increase in TUNEL positive cells. Higher vascular permeability was observed in ApoE-KO FD, evidenced by the Evans blue leakage and the albumin and α2-M extravasation. At this early stage of the DR, the GFAP expression levels were observed just in astrocytes but not in Müller glial cells (MC) demonstrating non-reactive gliosis in retinas of ApoE-KO FD, which correlated with the GS expression pointing out a normal function of MC. However, a reduction in GFAP immunoreactivity was observed in ApoE-KO FD whole mounts, which may be linked to a reduced ability to maintain BRB characteristics in ECs.

The results showed that ApoE-KO after 4 months of FD, which represent features of human MS, presented vascular dysfunction and neurodegeneration. Thus, this model could offer the opportunity to investigate DR at an early stage, whose prevalence has increased substantially worldwide.

Insulin resistance and obesity associated with the consumption of hyperlipidic diets are considered risk factors for the development of cognitive disorders and neurodegenerative diseases such as Alzheimer’s disease. Insulin resistance, inflammation and cognitive dysfunction are common manifestations in the context of both neurodegenerative and metabolic pathologies. Our objective is to study the effect of juvenile exposure to a moderately high fat diet (HFD), since weaning until 2 months of age, on cognitive performance and hippocampal glial and neuronal changes in C57BL/6 mice. HFD exposure induced an increase in blood glucose and peripheral inflammation shown by significantly augmented levels of seric IL1β ($p<0.05$), without changes in body weight. HFD mice showed alterations in spatial memory evidenced by the impaired performance in the novel object localization recognition test, a hippocampus-dependent task (Discrimination index= CD 33.89% vs HFD 14.11%, $p<0.01$). No significant differences were detected between groups in the elevated plus maze, a test employed to evaluate emotional behavior. Immunohistochemistry for Iba1 microglial marker allowed the analysis of morphologic alterations induced by HFD exposure. We found an enlargement in the soma size of Iba1+ cells ($p<0.01$) in response to HFD, evidencing a marked activation of this brain immune cell population. In consonance with the neuroinflammatory context and spatial memory deficits observed upon HFD, analysis of adult neurogenesis is now in progress, assessing the number and morphology of doublecortin + immature neurons in the dentate gyrus of the hippocampus. Our results indicate that juvenile consumption of a hyperlipidic diet promotes metabolic and inflammatory alterations that are associated with cognitive impairment and glial activation in the hippocampus, changes that could lead to neurological deficits in adulthood as well as in the development of neurodegenerative diseases.

Keywords: high fat diet, hippocampal neuroinflammation, cognitive impairment

(571) **INFLUENCE OF CHRONIC MILD STRESS IN METABOLIC AND BEHAVIOURAL ALTERATIONS INDUCED BY A HIGH FAT DIET. INVOLVEMENT OF NEUROTROPHINS AND CYTOKINES**

Nowadays obesity has become a worldwide disease affecting millions of people. Clinical studies have shown an association between cognitive impairment and obesity, marking it as a risk factor for dementia development, such as Alzheimer’s disease. In a previous study we’ve gathered evidence showing that in C57BL/6J mice, a high fat diet (HFD) decreases learning and memory capacity, and desregulates sugar metabolism. Chronic Mild Stress (CMS) enhanced the metabolic desregulation while causing anxious-like behaviour.The objective of this study is to analize the role of neurotrophin and cytokines expression in behavioural alterations and their potential use as conductual disfunction markers. For this purpose

one month old male C57BL/6J mice were randomly divided in two groups receiving either HFD (35% fat w/w) or standard diet (SD, 5% fat w/w) during 6 months. Two months after starting the diet, mice under HFD were randomly subdivided: One group received CMS and the other served as control. Cytokines and neurotrophins mRNA levels were determined in hippocampus and spleen by real-time RT-PCR, using GAPDH as housekeeper. In spleen, HFD+CMS increased both IL4 and IL10 mRNA levels ($p<0.05$ vs SD) while HFD and HFD+CMS lowered BDNF expression ($p<0.05$ vs SD). In hippocampus BDNF levels diminished non-significantly with HFD and HFD+CMS ($p=0.18$). Furthermore, we found a positive correlation between discrimination index and BDNF mRNA levels in both hippocampus (coefficient=0.52) and spleen (coefficient=0.62). No relevant correlations were found between neurotrophins or cytokines levels and anxious-like behaviour. In conclusion, neurotrophin and cytokine participate in behavioural alterations induced by HFD and/or HFD+CMS. In particular BDNF mRNA levels, both peripherical and central, correlated with cognitive performance. These findings suggest that BDNF expression in spleen could be a potential marker of cognitive deficit in obesity.

(046) **LONG-TERM CHANGES IN ANXIETY-LIKE BEHAVIOR FOLLOWING SUCROSE EXPOSURE IN JUVENILE VERSUS ADULT RATS.**

Maria Sol Kruse, Mariana Rey, Héctor Coirini
IByME-CONICET

Abstract: Sucrose consumption has increased dramatically in our society. This phenomenon is mainly associated with increased obesity and diabetes, among other metabolic disorders. The youngest populations have the highest sugar consumption and, during this period of life, profound changes occur as part of the maturation of the CNS. However, little is known about the impact of overconsumption of sucrose on the developing CNS. Here we studied the long-term effects of unlimited access of sugary water during the juvenile stage (childhood-adolescence) in the open field test. The animals are allowed to freely explore a 75 cm x 75 cm x 30 cm sand for 5 min. The session was recorded and the active time, distance traveled, rearing and grooming were analyzed using the ANY-maze© software. The arena was divided into 3 zones, the central zone 1, the intermediate zone 2 and the peripheral zone 3. Although we did not find differences in the total distance traveled nor the total active time between the four groups (juvenile control-sucrose and adult control-sucrose), significant differences were found by treatment-age interaction in the number of visited zones and the distance traveled in the central zones 1+2 (all, two-way ANOVA, $p<0.05$). A deeper analysis revealed that only the animals that consumed sucrose during youth visited less number of zones, evidenced by a decrease entries to the central zones 1+2 and the distance traveled there (all, one-way ANOVA, $p<0.05$). The rearing and grooming were also compromised in animals over-exposed to sucrose in the early stages of development. The two-way ANOVA showed significance by treatment-age interaction both in the number of times and the time invested to perform these actions. Altogether these results suggest that individuals exposed to sucrose consumption during their infancy-youth, but not during adulthood, explore less in the adult stage and present an anxious profile.

(199) **MATERNAL CAFETERIA DIET MODIFIES THE EXPRESSION OF DOPAMINERGIC RELATED-GENES IN THE RAT OFFSPRING BY EPIGENETIC MECHANISMS.**

Maria Florencia Rossetti, Rocio Schumacher, Cora Stoker, Gisela Paola Lazzarino, Maria Florencia Andreoli, Jorgelina Varayoud, Jorge Guillermo Ramos
Instituto de Salud y Ambiente del Litoral (ISAL), UNL-CONICET. Santa Fe, Argentina

The aim of the present study was to determine the effect of maternal cafeteria diet (CAF) on the expression of key genes related to the brain reward system in the offspring during the perinatal period. Female Wistar rats were fed with standard chow (CON) and/or CAF (snacks, biscuits, cookies, pudding, chocolate) from weaning. After 120 days of diet, females were randomly placed with Wistar males and vaginal smears were performed to confirm successful mating. Dams were maintained on their respective diets throughout pregnancy and lactation. Female offspring from CON and CAF dams were sacrificed on embryonic day 21 (E21) and postnatal day 10 (PND10). Offspring brains were removed and, using a micropunch technique, ventral tegmental area (VTA) and accumbens nucleus (NAc) were removed and stored at –80 °C. For mRNA analysis, real-time quantitative PCR was performed. For methylation studies, digestion with methylation-sensitive restriction enzymes followed by real-time PCR was used. Data was analyzed by two-way ANOVA and Bonferroni post-test; differences were significant at $p<0.05$. From PND1 to PND10, the body weight of pups from CAF dams was significantly lower than pups from CON dams. No changes in gene expression and methylation levels were found in the studied areas in E21. However, maternal CAF diet decreased the transcription of tyroxine hidroxylase (TH), dopamine receptor 2 (DRD2), dopamine transporter (DAT) and ghrelin receptor (GR) in VTA in the PND10. Interestingly, the changes in TH and DRD2 expression were related to the methylation status of their promoter regions. In NAc, maternal CAF diet reduced DRD1 and DRD2 expression in the offspring at PND10; although no alternations in their methylation patterns were detected. This study shows the importance of maternal nutrition during the perinatal period of their offspring and provides novel insights into the mechanisms through which maternal junk-food feeding can affect reward system in early postnatal life.

Keywords: maternal cafeteria diet; offspring; dopamine receptor; tyroxine hidroxylase; methylation.

(1534) **OPPOSING EFFECTS OF CATECHOLAMINERGIC AND SEROTONINERGIC SYSTEMS IN *C.elegans:* POTENTIAL IMPLICATIONS FOR HUMAN POSTTRAUMATIC STRESS DISORDERS**

María Gabriela Blanco, Tania Veuthey, Natalia Andersen, Diego Rayes, María José De Rosa
INIBIBB

Post-traumatic stress disorder (PTSD) is a clinical condition characterized by recurrent disrupting memories of a traumatic event, hyperarousal and anxiety. Despite it is known that PTSD patients exhibit high levels of catecholamines (CA), even in the absence of stress, the neural mechanisms underlying this condition are not understood. The selective serotonin (5-HT) reuptake inhibitors (SSRIs), paroxetine and sertraline, are the only drugs approved by the FDA for PTSD treatment. However, the role of 5-HT in PTSD and its relationship with CA is unknown and difficult to study in the complex human nervous system (NS). *C. elegans* is suited to provide insights into the crosstalk between 5-TH and CA as its NS is simple, has a defined neural wiring diagram and conserved neurotransmitter systems. Moreover, *C. elegans* coordinates stress response by releasing tyramine (TA) and octopamine (OA), which are structural and functional counterparts of CA, the mammalian “fight or flight” hormones.

We here studied parameters that, in *C. elegans*, depend on 5-HT such as egg laying, pharyngeal pumping and letargus. We exposed *tdc-1* and *tbh-1* null mutants (unable to synthetize TA and OA, respectively) to exogenous 5-HT. We found that these mutants are hypersensitive to 5-TH. Moreover, we observed a reduction in the pharyngeal pumping rate in *tph-1* null mutants (unable to synthetize 5-HT), which is partially rescued in *tph-1;tbh-1* double mutants. These results strongly suggest that 5-HT acts antagonistically to CA in *C. elegans*. These opposite actions could be conserved in mammals and explain the efficiency of SSRIs in PTSD treatment. We are now digging into the molecular and cellular underpinning of these antagonistic effects by analyzing mutants in serotonin receptors (many of them homologous to human 5-HT receptors). This study will widen the understanding of the mechanisms involved in neuronal regulation of stress response and could also provide new insights for PTDS treatment.

(278) **ATYPICAL ARRANGEMENT AND DISTRIBUTION**

OF KISSPEPTIN, NEUROKININ B AND DYNORPHIN A IN THE HYPOTHALAMUS OF VIZCACHA

Alejandro Raúl Schmidt, Pablo Ignacio Felipe Inserra, Santiago Elías Charif, Santiago Andres Cortasa, Sofía Proietto, María Clara Corso, Julia Halperin, Alfredo Daniel Vitullo, Veronica Berta Dorfman
CEBBAD Universidad Maimónides

Abstract: Considering that KNDy (kisspeptin, neurokinin B and Dynorphin A) cells are localized in the arcuate nucleus (ARC) of most mammals and modulate gonadotropin-releasing hormone (GnRH) expression and secretion, the aim of this work was to identify the presence of the KNDy cells in the hypothalamus of South American plains vizcacha (*Lagostomus maximus*) and its relation with GnRH and hormone receptors involved in reproduction. Adult non-pregnant female vizcachas were captured in the Estación de Cría de Animales Silvestres (ECAS) during March (n=7). Its brains were removed and fixed. Kluwer-Barrera staining was performed to determine ARC and anteroventral periventricular hypothalamic nucleus (AVPV) localization. To study KNDy cells arrangement, immunofluorescence followed by paired confocal microscopy was developed. NeurokininB (NKB), dynorphin-A (DYN), kisspeptin (Kiss), Kiss receptor (GPR54), GnRH, estrogen receptor alpha (ERα) and progesterone receptor (PR) were labelled. A few number of NKB/Dyn immunoreactive neurons, somas and fibers, were found in ARC. Surprisingly, NKB^+/Dyn^+ neurons were more abundant in AVPV than in ARC. However, Kiss was not detected in NKB^+/Dyn^+ neurons of both ARC and AVPV but were individually found in somas of AVPV and in fibers of ARC. In addition, GPR54 colocalized with GnRH in neurons of AVPV. Both $Kiss^+$ and NKB^+/Dyn^+ cells showed colocalization of ERα and PR. This is the first description of the KNDy components distribution in the hypothalamus of the vizcacha. An atypical arrengement of KNDy system was detected in AVPV. The expression of NKB/Dyn and Kiss in separate neurons and the lack of Kiss immunoreactive somas in ARC, suggest a singular model of KNDy system in the vizcacha with physical separation but possibly with a coordinated function. This results may indicate that GnRH neurons could be directly regulated by the hormonal environment via ERα and PR, and indirectly by Kiss and NKB/Dyn in *Lagostomus maximus*.

Keywords: Sexual dimorphism, KNDy, AVPV, ERα, vizcacha

(118) **ANALYSIS OF CEREBROSPINAL FLUID AMYLOID BETA 1-43 AS AN ALZHEIMER'S DISEASE BIOMARKER**

Nahuel Omar Carrizo, Patricio Chrem-Méndez, Ismael Calandri, Horacio Martinetto, Jorge Campos, Lucía Pertierra, María Julieta Russo, Ricardo Allegri, Gustavo Sevlever, Ezequiel I. Surace
Fundación para la Lucha contra las Enfermedades Neurológicas de la Infancia

Core biomarkers: amyloid beta 1-42 (Aβ42), total tau and phospho-tau have been included in the most recent diagnostic guidelines for Alzheimer's disease. New biomarkers are being intensively studied to improve diagnostic accuracy. Here, we have investigated cerebrospinal fluid amyloid beta 1-43 (Aβ43) in a group of patients with Dementia of Alzheimer's Type (DAT, n=10), Mild Cognitive Impairment (MCI, n=7) and 9 non-demented controls, using a commercially available ELISA kit. CSF Aβ43 levels were significantly decreased in DAT and MCI patients compared to controls (ANNOVA p=0.0484). Comparison of Aβ43 with the established biomarker Aβ42 revealed that both performed comparably well when analyzing receiver operating characteristic (ROC) curves between controls and DAT patients (area under the curve for Aβ43= 0.9222 vs AUC=0.9000 for Aβ42). Our results suggest that both biomarkers could be equally used as part of the diagnostic algorithm in Alzheimer's disease.

Keywords: alzheimer's disease, biomarker, diagnosis, amyloid beta

(543) **ATROGLIAL MGLU3R FUNCTIONS IN AGING ASTROCYTES AND HIPPOCAMPUS IN A MODEL OF ALZHEIMER DISEASE**

Juan Turati (1), Delia Ramirez (1), Lila Cariniglia (1), Julieta Saba (1), Carla Caruso (1), Juan Beauquis (2), Flavia Saravia (2), Daniela Durand (1), Mercedes Lasaga (1)
(1) INBIOMED, UBA-CONICET, Facultad de Medicina UBA. (2) IBYME. CONICET.

Our laboratory recently showed that metabotropic glutamate receptors (mGlu3R) in astrocytes presents a strong neuroprotective action against different inflammatory agents like NO and Aβ. Physiological cerebral aging is characterized by an increase in oxidative stress, neuroinflammation, which among others alterations compromise cognitive functions. As an in vitro aging model, we developed primary astrocytes cultures of 3 weeks (3w) and 9 weeks (9w), treating them with the mGlu3R agonist LY379268 (LY), 0.01μM/24hr. We found that the cells reach a senescence state at 9w (β-Galactosidase assay). Furthermore, we observed decreased cell viability at 9w, MTT assay. We also observed an important decrease of SOD activity comparing 9w astrocytes to 3w, while LY treatment induced a significant ($p<0.05$) increase of SOD activity in 9w astrocytes. Intracellular and extracellular Glutathione (GSH), show a significant increase comparing 9w to 3w non-treated astrocytes ($p<0.01$ and $p<0.05$). GSH production was not modified by LY. No group shows difference in ROS production. In order to characterize the expression profile of cognition-associated genes, we performed RT-qPCR from hippocampus of wild-type (wt) and transgenic (Tg) PDAPP-J20 mice of 5, 9, 14 and 20 month (m) old. mGlu3 mRNA levels were higher ($p<0.01$) in 9m-wt mice compared with 5m-wt mice and in 20m-Tg mice compared with 9m-Tg mice ($p<0.05$). We also found a significant difference ($p<0.05$) between wt and Tg mice at 9m. Serine Racemase (SR), D-Serine synthetic enzyme involved in memory, shows lower expression in 14m-Tg mice than 5m-Tg mice ($p<0.01$), we also found a significant difference ($p<0.05$) between wt and Tg mice at 5m. This results show changes in the expression of mGlu3 and SR during aging, whereas the expression pattern is modified in Tg animals. Besides, mGlu3 during aging could modulate the oxidative stress by increasing SOD levels.

Keywords: astrocytes, mGlu3R, aging, LY379268.

(1742) **THE ER-UNFOLDED PROTEIN RESPONSE MODULATES NEUROTOXICITY INDUCED BY DEMENTIA-ASSOCIATED AMYLOID PEPTIDES**

Nadia Irina Bocai, María Silvina Marcora, Lautaro Francisco Belfiori Carrasco, Laura Morelli, Corina Ileana García, Eduardo Miguel Castaño
Fundación Instituto Leloir- IIBBA CONICET

Alzheimer's disease (AD), the most common neurodegenerative disorder and Familiar Danish Dementia (FDD), a rare autosomal dominant disease, shares some features, including amyloid accumulation, ADan and Aβ respectively, progressive dementia and presence of neurofibrillary tangles.

Growing evidences suggest that amyloid accumulation induces ER stress in early stages of neurodegeneration. Disturbed ER homeostasis engages an adaptive reaction known as the unfolded protein response (UPR) that protects the cell against toxic misfolded proteins.

IRE1 activation, the most conserved UPR branch, includes the unconventional splicing of XBP1, a transcription factor that up-regulates genes related to protein folding (including BIP) and ER-mediated degradation.

In order to study the relation between UPR and amyloid peptides neurotoxicity we used transgenic *Drosophila melanogaster* lines.

The neuronal expression of ADan caused impairment in climbing ability in 3-day old flies, while in Aβ42 flies the impairment began at 21 days as compared to BRI2-23, a non-amyloidogenic control (ANOVA RM, $p<0.05$). To study UPR induction, we co-expressed each peptide with XBP1-GFP and found a correlation with IRE1/XBP1 activation and the onset of climbing dysfunction. In addition, HSC3/Bip levels measured in 14 day-old flies by Western blot, were higher in ADan than in Aβ42 (ANOVA $p<0.05$) These results indicate that these amyloid peptides can induce early UPR activation that correlate with the severity of their toxicity.

Modulation of XBP1 levels by down-regulation enhanced neu-

rotoxicity and the accumulation of Aβ42, while overexpression reduced Aβ42 and improved geotaxis in old flies (ANOVA p<0.01). Our results indicate that IRE1/XBP1 activation is neuroprotective and enhances Aβ42 clearance. Further analyzes with ADan expressing flies are being performed. Understading the role of UPR activation in early stages of disease may help to develop new treatments to delay the onset of dementia.

Keywords: Neurodegeneration, Aβ, Adan, Upr, Xbp1.

(413) **ROLE OF APP/GO PROTEIN Gβγ COMPLEX SIGNALING ON Aβ NEURODEGENERATION IN ALZHEIMER´S DISEASE MODELS**

Anahi Bignante (1), Nicolás Ponce (1), Florencia Heredia (1), Juliana Musso (1), María Krawczyk (2), Julieta Millán (2), Gustavo Pigino (1), Mariano Boccia (2), Alfredo Lorenzo (1)
INIMEC-CONICET. (2) Laboratorio de Neurofarmacología de los Procesos de Memoria, Cátedra de Farmacología, Facultad de Farmacia y Bioquímica, UBA.

Deposition of amyloid-β peptides (Aβ) causes neurodegeneration in Alzheimer's disease (AD). Aβ is generated by regulated proteolysis of the amyloid precursor protein (APP). However, the involvement of APP, beyond its role as source of Aβ, in the mechanism of Aβ-induced degeneration remains elusive. Methods. FRET and co-immunoprecipitation were performed in primary hippocampal cultures and HEK293T in order to identify the effect of Aβ on APP and Go interaction. The physiopathological relevance of APP and Go signaling in Aβ neurodegeneration was determined by analyzing neuronal dystrophy, tau phosphorylation and neuronal death in primary hippocampal cultures and by assessment of memory performance in the 3xTgAD mice using the novel object recognition (NOR) test. Results. We found that toxic Aβ assemblies enhance APP and Go interaction ($p < 0.001$). APP overexpression renders hippocampal neurons vulnerable to Aβ-toxicity by a mechanism that requires Go-Gβγ signaling and p38-MAPK activation ($p<0.05$). We used gallein, a pharmacological inhibitor of Gβγ complex, to demonstrate that the activation of Go protein Gβγ complex mediates Aβ-induced p38-MAPK activation and neuronal degeneration ($p < 0.001$). In mature hippocampal cultures expressing endogenous proteins, treatment with gallein and PD503208 reduced neuronal degeneration, tau phosphorylation at the PHF-1 epitope induced by toxic Aβ assemblies ($p < 0.05$). Gallein also inhibited Aβ-induced synaptic loss in hippocampal cultures ($p < 0.001$). Finally, in the 3xTgAD mice, an AD model, acute application of gallein in dorsal hippocampus restores memory performance in the NOR test ($p < 0.05$). Conclusions. Our data reveal that APP/Go-Gβγ complex is a signaling hub potentially relevant for developing therapies for halting Aβ-degeneration and cognitive dysfunction in AD based on a molecular disease mechanism. Keywords. Alzheimer, Aβ, APP, Go protein, Gβγ complex, degeneration, tau phosphorylation, gallein, p38 MAPK, 3xTg-AD.

In our laboratory, we have previously studied the role of phospholipase-mediated signaling in different models of neuronal injury. In this work, our aim was to characterize the effect of wild type α-synuclein (WT α-syn) overexpression on phospholipase D (PLD) pathway in a human neuroblastoma cell line. Immunocytochemistry showed a significant decrease in the neuronal marker neurofilament (NF) expression and a rise in F-actin foci in WT α-syn cells compared with control cells (pcDNA3) ($p<0.001$). Experiments of immunocytochemistry and Western blot demonstrated a diminished PLD1 expression level in WT α-syn cells ($p<0.001$).

To elucidate the implication of PLD in NF expression, we treated untransfected cells with PLD1 and PLD2 pharmacological inhibitors (EVJ and APV, respectively). We observed a decrease in NF levels only upon EVJ treatment ($p<0.001$). To confirm the inhibitor effect, we also tested PLD activity by using the transphosphatidylation assay as a phosphatidic acid (PA) production marker. We found that in untransfected cells NF loss was related with PA produced by PLD1 ($p<0.01$). Moreover, WT α-syn cells treated with EVJ showed almost complete abolishment of NF expression and increased foci of actin polymerization in the cellular periphery ($p<0.05$; $p<0.001$).

Finally, we found that constitutively active eGFP-PLD1 expression restores NF levels in WT α-syn cells but increases the apoptotic marker cleaved caspase-3 ($p<0.001$). Our results lead us to conclude that the neuronal phenotype loss, characterized by NF diminution, could be a protective mechanism mediated by PA signaling.

Keywords: α-synuclein, neurofilament, phospholipase D1, neurodegeneration

(1022) **EVALUATION OF GENES IMPLICATED IN NEURONAL PLASTICITY AS POTENTIAL PERIPHERAL MARKERS OF COGNITIVE DEFICIT.**

Alejandro David Moroni (1,2), Ana María Genaro (2,3), María Laura Palumbo (1, 2)
(1)Centro de Investigaciones y Transferencia del Noroeste de la Provincia de Buenos Aires (CIT NOBA) - Universidad Nacional del Noroeste de la Provincia de Buenos Aires (UNNOBA), (2) Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Junín, Buenos Aires, Argentina, (3) Universidad de Buenos Aires (UBA), Facultad de Medicina, Primera Cátedra de Farmacología, Argentina, Instituto de Investigaciones Biomédicas (BIOMED) - Pontificia Universidad Católica Argentina (UCA) - Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), C.A.B.A, Argentina.

Abstract: The hippocampus is a brain-structure related with learning and memory. Hippocampus is sensitive to the stress effects. In previous reports, we found that chronic mild stress (CMS) model induced cognitive deficit in mice. This was correlated with a decrease in adult neurogenesis and Th1/Th2 balance in lymphocytes. We also observed a decrease in neural nitric oxide synthase (nNOS) activity and protein levels and an increase in endothelial nitric oxide synthase (eNOS) in hippocampus of CMS mice. Moreover, other authors related the genes G protein subunit alpha q (GNAQ), cAMP responsive element binding protein (CREB) and glycogen synthase kinase 3 beta (GSK-3β) with plasticity neuronal process such as neurogenesis, neuronal differentiation, dendritic growth and in several psychiatric disorders. All these genes are expressed in lymphocytes. The aim of the present work was correlate the eNOS, nNOS, GNAQ, CREB and GSK-3β genes expression in hippocampus, lymph nodes and spleen with cognitive deficit in female BALB/c mice exposed to CMS model. The spontaneous alternation percentage was evaluated by Y-maze. We found a poor performance in the Y-maze in CMS mice respect to control mice ($p<0.01$). The mRNA levels of the all genes were analyzed by qRT-PCR. The mRNA level of eNOS ($p<0.05$), nNOS ($p<0.05$) and GNAQ ($p<0.05$) decrease in hippocampus and nNOS ($p<0.05$) level decease in lymph nodes of stressed mice respect to control. The GNAQ ($p<0.05$), GSK-3β ($p<0.01$) and CREB ($p<0.01$) expression decrease in spleen of CMS mice. The other genes did not show significant differences in the studied tissues. These findings indicate the nNOS and GNAQ genes could be potential peripheral markers of cognitive deficit. More studies are necessary to demonstrated this hypothesis.

Keywords: peripheral markers, neuronal plasticity genes, cognitive deficit, chronic stress.

Alzheimer's disease (AD) is the most common form of dementia. Although the pathogenesis of AD remains cryptic, this pathology is associated with an imbalance in the production and clearance of amyloid-β protein (Aβ). Aβ deposition and neuroinflammation are recognized hallmarks in AD, affecting mainly the brain cortex and hippocampus, both in patients and animal models. The glycan-binding protein galectin-1 (Gal1) modulates several properties on immune and endothelial cells in peripheral and central nervous system compartments, where a neuroprotective role was proposed in experimental settings of autoimmune encephalomyelitis. Here, we administered Gal1 or vehicle control (i.p. 9 injections of 100 ug/dose) during 3 weeks to 12 months-old PDAPPJ20 transgenic mice, or age-matched non-transgenic animals. The Gal1 treated group displayed a significantly improved cognitive response in the Novel Object Location Recognition test ($p<0.05$). Amyloid+ area assessed by Congo Red staining in the hippocampus was decreased by 53,5% ($p<0.05$). In addition, labelling with the tomato lectin to identify the microvasculature combined with immunofluorescence against amyloid (4G8) around vessels, revealed a strong reduction in perivascular-located deposits ($p<0.05$) but no changes in vascular morphology. Moreover, we detected a trend of reduction of the perivascular Aquaporin-4 protein in astrocytic endfeet in AD mice and a trend towards recovery of water channel protein -crucial for clearance of Aβ in the brain via lymphatic clearance and glial degradation, besides modulation of the synaptic function -after Gal1 treatment. Additional *in vitro* experiments employing endothelial and glial cells are in progress to elucidate the mechanisms by which Gal1 controls the integrity and function of the neurovascular unit in AD.

Pathological accumulation of α-synuclein (α-syn), a cytosolic protein highly expressed in the central nervous system, is a hallmark of Parkinson's disease. α-syn has the ability to bind lipids, although its involvement in lipid metabolism remains unknown. In previous work, we reported that the overexpression of A53T α-syn in dopaminergic neurons increased the cellular content of neutral lipids and fatty acids (SAIB 2014-2015). The aim of the present study was to characterize the role of α-syn in neuronal lipid metabolism. For this purpose, we worked with a human neuroblastoma cell line, IMR-32, that stably express the wild type form of α-syn (WT α-syn). We observed an increase in triacylglycerides (TAG) and cholesterol content in WT α-syn neurons when compared with control cells (pcDNA3) (**$p<0.01$ and ***$p<0.001$, respectively). In consonance with these findings, lipid droplets (LD) accumulation in WT α-syn neurons was detected. Moreover, the number and the size of LD in the presence of α-syn were increased when LD formation was induced by oleic acid (300 y 600 μM). Enhancers of α-syn toxicity such as iron, manganese and bortezomib, which increased protein aggregation, potentiated LD accumulation in WT α-syn neurons. Finally, the pharmacological inhibition of lipins (propranolol) reduced the viability of WT α-syn neurons with respect to controls (**$p<0.01$), thus suggesting that the blockage of TAG synthesis turned the neurons more vulnerable to the presence of α-syn. Our results allow us to conclude that neurons trigger the accumulation of LD as a neuroprotective mechanism against α-syn, and that this novel mechanism could be involved in the determination of neuronal fate. Sponsored by FONCyT-CONICET-UNS.

Keywords: α-synuclein, lipid metabolism, lipid droplets, neurodegeneration.

Among metabotropic glutamate receptors (mGluR), astroglial mGlu3R subtype has particularly shown a broad range of neuroprotective functions. Our previous results demonstrated that mGlu3R activation by the synthetic agonist LY379268 promotes non-amyloidogenic APP cleavage, thereby releasing sAPPα neuroprotective fragment from astrocytes. Moreover, sAPPα mediates the antiapoptotic effect of conditioned medium from LY379268-treated astrocytes (LY-ACM) against Aβ toxicity in hippocampal neurons. We also showed that LY379268 increases Aβ uptake by astrocytes, which parallels the reduction in co-cultured neuron death. In order to elucidate the mechanism involved in Aβ uptake by astrocytes, the present study shows that LY-ACM increased HiLyte Fluor-$A\beta_{25\text{-}35}$ uptake by naïve astrocytes ($p<0.05$) and that sAPPα depletion from LY-ACM blocked this effect. Accordingly, recombinant sAPPα (1 ηM) also increased Aβ uptake ($p<0.01$). Since LY379268 (0.1 μM) increased gene expression of class-A scavenger receptor (SR-A) in astrocytes ($p<0.05$), we determined whether SR-A mediates mGlu3R-induced Aβ uptake by using astrocyte cultures derived from SR-A knockout mice. We found that LY379268 as well as sAPPα effects on Aβ uptake were abolished in SR-A-deficient astrocytes ($p<0.05$), indicating the participation of this scavenger receptor in Aβ phagocytosis by astrocytes. When Aβ was added to the wells containing LY379268 or recombinant sAPPα in wild-type astrocytes, the effect of sAPPα on Aβ uptake was abolished, whereas the effect of LY379268 was decreased by over 40%, suggesting that remaining sAPPα in the culture medium might interfere with Aβ binding to SR-A. Our results shed light on a novel neuroprotective pathway that not only prevents Aβ neurotoxicity but also promotes Aβ clearance.

Bioenergetic dysfunction has been suggested as an early event and as a cause for synaptic deficiency and cognitive impairment in Alzheimer disease (AD). It has been proposed that energy dysfunction can be dynamically tested in Platelets (PLTs). PLTs are good candidates to find peripheral biomarkers for AD because may reflect in periphery the inflammatory and oxidative stress that happens in the brain. We aimed to perform a time-course analysis of PLTs isolated from peripheral blood of control (CNT) and hemizygous McGill-R-Thy1-APP transgenic (Tg+/-) rats, a well characterized model of early AD. We used an extracelular flux analyzer (Seahorse XFp) and 2 different approaches: MitoStress (evaluates mitochondria functionality) and GlycoStress (asseses glycolitic performance). Animals (n= 3-6/group) from 3-12 month-old were anestethized, beheaded and blood (10 ml) recovered in sterile tubes containing Citrate Buffer/Dextrose (pH 7.4). PLTs were isolated by sequential centrifugation at room temperatura to avoid activation. Quantification was performed by hematologic analyzer (Mindray 5800). $15x10^6$ PLTs/well were seeded in XFp Cell Culture MiniPlates and centrifuged (1500g/15 min), afterthat supernatant was removed and MitoStress and GlycoStress performed. We set-up a method to evaluate mitochondrial activity in PLTs and are able to plot profiles to compare CNT vs. Tg(+/-). By contrast to synaptosomes, PLTs do not have spare respiratory capacity, it means that are not involved in process-

es that requiere extra ATP when energy demand increases, such as synaptic functionality and cognition. This result is in agreement with the phisyological role of PLTs. Preliminary data show that bioenergetic parameters of PLTs from 6 month-old Tg(+/-) are similar to CNT. Our results are in the context of a transgenic model and further validation is required in PLTs derived from blood of AD and CNT subjects to determine the relevance of PLTs bioenergetic as a peripheral biomarker for AD.

(1454) **ACTIVATION OF THE GPR30 RECEPTOR INHIBITS ALDOSTERONE-INDUCED CARDIAC HYPERTROPHY**

Romina Di Mattia, Alejandro Aiello, Alejandro Orlowski
Centro de Investigaciones Cardiovasculares Dr. Horacio E. Cingolani

GPR30 was first described as a membrane orphan G protein-coupled receptor. Later it was demonstrated that estrogen can act as a receptor ligand. It has been reported that the activation of GPR30 is cardioprotective. The administration of its synthetic ligand G1 reduced the infarct size in ischemia-reperfusion, attenuated heart failure and induced a decrease in perivascular fibrosis. The steroid hormone aldosterone (Ald) plays a classic role acting through mineralocorticoid receptor (MR) and its activation on the cardiovascular system generates cardiac hypertrophy, fibrosis and heart failure. It has been recently proposed that certain non-genomic effects of Ald are due to the activation of GPR30. However these results are in contraposition with the beneficial effects of GPR30 activation. The aim of this work was to evaluate the role of GPR30 activation in a model of hypertrophy induced by Ald. We cultured neonatal rat cardiomyocytes (NRCM) from 1-3 days Wistar rats and treated them for 48 hours with Ald (10nM), G1 (1uM) or the combination of both. Hypertrophy caused by Ald was attenuated by the co-treatment with G1 (cellular area % respect to control,Control:1±0.07,n =9;Ald:1.33±0.05*,n=8;Ald+G1:0.93±0.05,n=7;*p<0.05). We also studied the expression of the hypertrophic marker BNP. We found a significant increase in BNP expression in those cells treated with Ald, which was abrogated by G1 co-treatment (BNP/GAPDH expression,Control:1±0.34,n=9; Ald:2.81±0.89*,n=6,Ald+G1:1.13±0.47,n=6;*p<0.05). To analyze the involvement of MR and GPR30 in cardiac hypertrophy development, we transfected NRCM with siRNAs against them (siMR and siGPR30) during Ald treatment. We obtained preliminaries results showing that Ald-induced hypertrophy was prevented by siMR and not affected by siGPR30, indicating that MR is responsible for Ald induced hypertrophy. Overall, the present data indicate that the MR-dependent Ald-induced hypertrophy is prevented by GPR30 activation by G1, suggesting the possibility of considering this receptor a novel therapeutic target for the treatment of this pathology.

The increase in blood pressure variability (BPV) has been established as an independent risk factor for the development of target organ damage in hypertensive patients. The aim was to evaluate the effects of the treatment of different antihypertensive agents on central arterial pressure, BPV and target organ damage in spontaneously hypertensive rats (SHR). Male SHR (200-250 g) received vehicle (n=6), carvedilol 15 mg/kg (n=6) or losartan 10 mg/kg (n=6) for 8 weeks. A fourth group of Wistar rats were used as normotensive control (n=6). At the end of the treatment, echocardiographic evaluation, direct and indirect blood pressure (BP) and short-term variability measurements were performed. Left ventricle was removed to assess ventricular hypertrophy.

Chronic treatment with losartan, but not carvedilol, reduced indirect systolic BP. Both carvedilol and losartan diminished its intraday fluctuation compared to SHR. Also, both drugs significantly decreased carotid SBP and its short-term variability. Left ventricular mass was significantly reduced by chronic treatment with carvedilol (2.70±0.04 mg/g; P<0.05 vs. vehicle) or losartan (2.70±0.08 mg/g; P<0.05 vs. vehicle) when compared with SHR treated with vehicle (3.51±0.19 mg/g). Echocardiographic evaluations revealed that carvedilol or losartan revert diastolic anterior wall thickness, diastolic posterior wall thickness, systolic posterior wall thickness and isovolumic relaxation time. Chronic treatment with carvedilol, but not losartan, normalized systolic posterior wall thickness. In conclusion, both carvedilol and losartan are effective in the reduction of central BP and its short-term variability in SHR, resulting in an attenuation of ventricular hypertrophy evidenced by morphological and echocardiographic parameters.

Keywords: hypertension, carvedilol, losartan, echocardiography.

(1134) **EFFECT OF CHRONIC TREATMENT WITH SILDENAFIL ON CARDIAC HYPERTROPHY**

Daiana Escudero (1), Gisel Diaz (1), Carolina Ciancio (1), Andres Pinilla (1), Leandro Di Cianni (1), Enrique Portiansky (2), Gustavo Perez (1)
(1) Centro de Investigaciones Cardiovasculares Dr. Horacio E. Cingolani, Facultad de Ciencias Médicas de La Plata (UNLP), (2) Catedra De Patologia General Veterinaria - Facultad De Cs.Veterinarias - (UNLP) Universidad Nacional De La Plata

Previously, we showed that myocardial Na^+/H^+ exchanger (NHE1) hyperactivity is responsible of cardiac hypertrophy (CH) development in spontaneously hypertensive rats (SHR), also that the increased in protein Kinase G (PKG) activity after phosphodiesterase-5A (PDE5A) inhibition (Sildenafil, "SIL") inhibits NHE1. Current study was aimed to evaluate the ability of chronic SIL treatment to reverse hypertrophy. As an initial approach, H9C2 cells were treated during 48hs with several doses of Angiotensin II (AngII) to induce growth (evaluated by measuring cell area in percent of control). A dose of 10nM AngII was then selected. A significant increase in cell area was detected after 24hs of AngII: 129±6 vs.100±5% (control), n=4, effect that was larger after 48hs: 154±8%. Addition of SIL during the last 24hs of AngII treatment promoted a significant dose-dependent decrease in cell area: 126±5% (5μM), 114±4% (10μM). To evaluate in vivo the effect of SIL on CH, 4-months old SHR rats were chronically treated (3 months) with SIL (100mg/kg/day) orally through drinking water (SHR+SIL) and compared to age-matched untreated controls (SHR). SIL reduced CH (left ventricular weight to body weight ratio: 2.69±0.04 vs. 2.52±0.05, p<0.05), myocardial interstitial fibrosis (percentage of total collagen: 1.82±0.01% vs. 1.38±0.01%, p<0.05) and myocardial stiffness (evaluated by length-tension curves in isolated papillary muscles, p<0.05, 2-wayANOVA). In addition, a decreased NHE1 activity, determined by H^+ efflux at pH_i 6.8 during the recovery from a transient acidosis, was detected in isolated papillary muscles from SHR+SIL group (1.19±0.7 mM/min) compared to non-treated controls (4.19±0.8 mM/min, p<0.05). In summary, chronic SIL treatment was able to reverse either AngII-induced H9C2 cells growth or CH in SHR. The fact that NHE1 activity was found depressed in SHR+SIL group suggests that a PKG-induced exchanger inhibition would be responsible for the antihypertrophic effect of SIL.

Key word: Sildenafil-NHE1-cardiac hypertrophy

(1132) **EFFECTS OF BIOACCESSIBLE GARLIC COMPOUNDS ON CULTURED VASCULAR SMOOTH MUSCLE**

CELLS FROM SPONTANEOUSLY HYPERTENSIVE RATS.

Abstract: Several studies have associated a moderate consumption of garlic with improvements in health. The evidence suggests that its medicinal activities are mainly due to the organosulfur compounds (OSCs) content. Nevertheless, OSCs can have different activities/potency on different cell lines or tissues. Moreover, after garlic consumption, only the bioavailable compounds will have bioefficacy. In this regard, previous works have identified only a few OSCs in blood. In this work it is desired to evaluate the proliferation and migration of vascular smooth muscle cells (SMCs), phenomena that contribute to the remodeling of small arteries and complicate hypertension. Three bioaccessible OSCs, allyl mercaptan (AM), S-allyl cysteine (SAC) and 2-vinyl-4H-1,3-dithiin (2VD), were selected to evaluate their effects on SMCs isolated from mesenteric arteries of spontaneously hypertensive rats. Cell proliferation by MTT assay, cell migration by scrape-wound migration assay and intracellular oxidative stress by fluorometric CM-H2DCFDA assay were evaluated after cell exposure to OSCs expected quantities in plasma, 10 μg/L of AM and 2VD and 50 μg/L of SAC. The MTT results showed that 2VD significantly decreased the rate of proliferation 20% compared to the control. Migration assay showed that 2VD and AM reduced significantly cell migration, around 30%. Concerning to the intracellular ROS levels, the compounds showed different behaviors; while AM and SAC behaved as intracellular antioxidants, 2VD showed a slight tendency to increase the oxidative stress. In conclusion, expected quantities of 2VD and AM in plasma, provided by garlic intake, were able to inhibit the migration of SMCs of spontaneously hypertensive rats. These compounds could help to protect the cardiovascular system from vascular remodeling produced by hypertension. Further studies will be needed to elucidate their action mechanisms and the role of its different antioxidant effects.

Keywords: Organosulfur compounds, garlic, hypertension, vascular remodeling.

(066) **FEMALE MICE EXPOSED TO EARLY LIFE STRESS DISPLAY ANGIOTENSIN II-DEPENDENT OBESITY-INDUCED HYPERTENSION**

Analia Loria

Previously, we have shown that female mice subjected to maternal separation with early weaning (MSEW), a model of postnatal neglect, display exacerbated diet-induced obesity and high blood pressure (BP) compared with control mice. Female MSEW mice show activated renin-angiotensin system, including increased plasma renin activity and adipose tissue-derived angiotensinogen secretion. This study tested the hypothesis that augmented obesity-induced hypertension in female MSEW mice is AngII-dependent. Mouse MSEW was achieved by repeated, daily separations from the dam and weaned 4 days early. Normally reared controls (C) were weaned at postnatal day 21. Each experimental group of female weanlings was placed on high fat diet (HFD, 60% kcal from fat). After 18 weeks, mice were implanted with radiotelemetry devices for BP measurement. At week 20, average 24-hr systolic blood pressure (SBP) was 134±2 mmHg in MSEW mice and 126±2 mmHg in C ($P<0.05$). We also determined the BP sensitivity to the acute administration of AngII (1, 10 and 50 ug/kg, s.c.). AngII-induced BP changes, assessed by BP area under the curve, were similar between MSEW and C mice at all doses (50 ug/kg dose:145±10 vs. 132±15 mmHgx30 min, respectively). Chronic enalapril treatment (2.5 mg/kg/day, drinking water) was conducted for 7 days. Enalapril reduced SBP 15±2 mmHg in MSEW mice but only 6±1 mmHg in C mice ($p<0.05$). The BP response to acute AngII doses increased similarly in MSEW and C enalapril-treated mice, (50 ug/kg: 200±13 vs. 207±22 mmHgx30 min, respectively). In addition, BP and HR responses to acute injections of mecamylamine (5 mg/kg), propranolol (5 mg/kg) or atropine (1 mg/kg) were similar between untreated MSEW and C mice, suggesting that exacerbated BP in female MSEW mice is independent of sympathetic or parasympathetic dysfunction. Taken together, these data provide evidence that increased BP in female MSEW mice results from elevated circulating AngII rather than enhanced AngII sensitivity.

Keywords: Early life stress, females, obesity, hypertension, Angiotensin II

(1635) **HYPERPOLARIZING MECHANISMS AND ENDOTHELIN APPERANTLY INFLUENCE ANGIOTENSIN II RESPONSES ON AORTAS OF RATS SUBMITTED TO ADJUVANT INDUCED ARTHRITIS (AIA)**

Gabriela Palma Zochio Tozzato (1), Agnaldo Bruno Chies (2)
(1) São Paulo University State (UNESP), Institute of Biosciences, Campus Botucatu, SP – Brazil. (2) Marília Medical School (FAMEMA), Laboratory of Pharmacology, Marília, SP – Brazil.

This study aimed to investigate the effects of adjuvant induced arthritis (AIA) on the aorta responses of rat to angiotensin (Ang II) and acetylcholine (ACh). Moreover, to determine if these changes may be influenced by a reduction of plasma testosterone. Male Wistar rats were distributed in ORQ (orchiectomy), AIA, ORQ/AIA and control. Twenty-one days after the onset of AIA aortic rings were set up in organ bath. Values of pEC50 (Log of EC_{50}) and maximal response (R_{max}; in grams), were compared by two-way ANOVA/Tukey - $P<0,05$. No changes of ACh or Ang II responses were observed due to AIA and/or ORQ, in aorta with or without endothelium. In the presence of L-NAME, the Ang II R_{max} in Control (0,44±0,09) was higher ($P<0,0001$) than in AIA animals (0,13±0,03). A similar profile of Ang II responses between groups was observed in the presence of 1400W, but without any statistical difference. In the presence of L-NAME plus depolarizing krebs solution (KCl 60mmol/L) or BQ123, the difference observed in the presence of only L-NAME were no longer observed. In the presence of Apocinin, Ang II R_{max} and pEC_{50} were higher in the ORQ than in the ORQ/AIA group (R_{max}: 0,27±0,06 and 0,09±0,02, respectively; $P<0,0007$; pEC_{50}: 8,10±0,15 and 7.54±0,21, respectively; $P<0,01$). Neither AIA nor ORQ change Ang II responses whether endothelial mechanisms are present. The inhibition of endothelial NO-related mechanisms stands out higher Ang II responses in control animals. This increase depends partially on testosterone levels since it is smaller in ORQ animals. However, this elevation of Ang II responses that may be observed only in absence of NO, can be blunted if hyperpolarizing mechanisms and ETA receptors are blocked. It suggests a cooperation between hyperpolarizing mechanisms and endothelin-1 to keep reduced the Ang II aorta responses in AIA animals.

(498) **LOSARTAN IMPAIRS HEXACHLOROBENZENE-INDUCED HYPERTENSION AND MODIFIES THE MECHANO-ENERGETIC RESPONSE OF RAT HEARTS TO ISCHEMIA/REPERFUSION INJURY**

Patricia Bonazzola (1), Giselle Romero Caimi (2), María Inés Rosón (1), Susana Gorzalczany (3), Cecilia Villa Etchegoyen (1), Laura Alvarez (2), Rocío Castilla (1)
(1) Instituto de investigaciones Cardiológicas (ININCA) UBA-CONICET. (2) Laboratorio de Efectos Biológicos de Contaminantes Ambientales, Dpto de Bioquímica Humana, Facultad de Medicina, UBA. (3) Cátedra de Farmacología, Facultad de Farmacia y Bioquímica, UBA.

We have shown that the bio-accumulated organ chlorinade pesticide hexachlorobenzene (HCB) produces hypertension (Hyp) in rats, probably through an increase in arterial angiotensine II receptor 1 (AT1) expression. Also we showed an increase in post ischemic contractile recovery (PICR) and economy for contraction (Eco) in isolated hearts from HCB-treated rats, a potential adaptative response to pesticide-induced Hyp.

Here, we study the role of AT1 in HCB-induced Hyp by means of AT1 antagonist Losartan (L) treatment, focusing on heart contractile and energetic response to an ischemic insult.

Male Wistar rats were treated with 500 mg/kg HCB and with 30 mg/kg L for 45 days. Hearts were used for histological analysis or mechanical and energy assays. To this end, simultaneous mechanical and heat measurements were done in hearts arterially perfused

at 37ºC by Langendorff method, paced at 3 Hz, and exposed to 25 min ischemia followed by 45 min. reperfusion (R).

L prevented HCB-induced Hyp (110.5±8.2, vs 145.5±5.1 mmHg, p<0.05).

Hearts from HCB-treated rats showed a decrease in resting pressure (RP) during R (58.5±4.5 vs 89.2±6.3 mmHg, p<0.05). Neither L nor L+HCB altered RP vs HCB alone (66.5±6.1, 65.33±10.0% for L and L+HCB, respectively).

An improvement of PICR was observed in hearts from HCB- and L-treated rats (46.2±6.0, 39.8±7.4, 18.8±2.3%, for HCB, L and C, respectively, p<0.05 at 45 min of R). L+HCB prevented the HCB-induced increase in PICR (20.2±6.1%, p<0.05 at 45 min of R).

HCB did not alter total heat production (Ht), while L and L+HCB increased it (83.8±6.5, 79.5±5.6, 56.3±4.7% for L, L+HCB and C respectively, p< 0.05).

HCB increased Eco during R (67.8±7.2 vs. 35.0±5.1%, p<0.05 at 45 min R) and neither L nor L+HCB modified it.

Conclusion: L diminished HCB-induced Hyp. The impairment by L of cardiac HCB-induced mechanic and energetic effects suggests that HCB heart protection is a response to HCB-induced Hyp.

Zinc deficiency (ZD) programs cardiovascular alterations in male rats.

Objective: To evaluate the cardiovascular effects of chronic infusion with angiotensin II (AII) in male rats subjected to prenatal and postnatal ZD.

Method: Wistar rats fed during pregnancy until weaning control (C,30ppm) or zinc deficient (B,8ppm) diets. At weaning, C male offspring continued on C diet (CC) and B offspring received B or C diets for 60 days (BB, BC). At 67 days of life, subcutaneous infusions of AII (65 ng/min/rat) or 0.9% NaCl were administered to animals for 14 days using osmotic pumps (Model 2002,Alzet,Palo Alto,USA). Systolic blood pressure (SBP,tail-cuff method,mmHg); cardiac(C) and aortic(A) inflammatory markers (TNFα,IL-6;IHQ; %area marked/total tissue area); perivascular collagen/lumen area(C/L) and media/lumen area(M/L) of A and C arteries (sirius red staining) were determined at 81 days. ANOVA, Bonferroni post-hoc test(n=6/group,$^{\alpha}$p<0.05 vs CC,$^{\delta}$p<0.05 vs BB,$^{\psi}$p<0.05 vs BC)

Results: SBP(CC:120±3;CCAII:165±5$^{\alpha}$;BB:140±3$^{\alpha}$;BBAII:188±6$^{\delta}$;BC:137±1$^{\alpha}$;BCAII:193±3$^{\psi}$)

In C

C/L(CC:1,37±0,20;CCAII:2,68±0,23$^{\alpha}$;BB:2,71±0,32$^{\alpha}$;BBAII:2,30±0,66;BC:2,16±0,18$^{\alpha}$;BCAII:2,83±0,17)

TNFα(CC:3.7±0.9;CCAII:19.4±2.8$^{\alpha}$;BB:17.7±1.0$^{\alpha}$;BBAII:22.2±1.0$^{\delta}$;BC:19.6±0.9$^{\alpha}$;BCAII:22.7±1.0$^{\psi}$)

IL-6(CC:3.3±1.6;CCAII:18.1±1.7$^{\alpha}$;BB:17.3±1.8$^{\alpha}$;BBAII:21.0±1.4$^{\delta}$;

BC:17.5±1.9$^{\alpha}$;BCAII:20.5±1.3$^{\psi}$)

In A

M/L(CC:0,14±0,02;CCAII:0,28±0,02$^{\alpha}$;BB:0,23±0,01$^{\alpha}$;BBAII:0,39±0,03$^{\delta}$;BC:0,17±0,01;BCAII: 0,31±0,01$^{\psi}$)

TNFα(CC:1.5±0.5;CCAII:17.0±1.9$^{\alpha}$;BB:15.7±1.7$^{\alpha}$;BBAII:30.6±2.0$^{\delta}$;BC:15.4±1.6$^{\alpha}$;BCAII:31.2±2.3$^{\psi}$)

IL-6(CC:2.1±0.4;CCAII:22.3±2.2$^{\alpha}$;BB:20.8±1.6$^{\alpha}$;BBAII:31.7±1.7$^{\delta}$;BC:21.4±1.9$^{\alpha}$;BCAII:30.4±1.6$^{\psi}$)

C:M/L, A:C/L: No differences.

Conclusion: ZD exacerbates AII effects on SBP. AII enhanced the expression of inflammatory interleukins in C and A. This increase was lower in BBAII and BCAII animals due an exacerbated inflammatory state without treatment with AII. C arteries from BB and BC showed increased C/L. In A, BB showed higher M/L. AII increased M/L in all groups.

Key words: zinc deficiency, angiotensin II, cardiovascular system, fetal and postnatal life

(1428) **SEX DIFFERENCES IN BLOOD PRESSURE RESPONSE TO CONTINUOUS ANG II INFUSION: INVOLVEMENT OF SEX CHROMOSOME COMPLEMENT AND HORMONAL EFFECTS**

Florencia Dadam, Laura Vivas, Ximena E. Caeiro

Instituto de Investigación Médica M. y M.Ferreyra, INIMEC-CONICET-Universidad Nacional de Córdoba

A growing body of evidence demonstrate that the pressor response to AngII is sexually dimorphic under physiological and pathophysiological circumstances. But why do male and female show differences in rennin angiotensin system (RAS) activation and inhibition? Sex steroids can induce organizational (long-lasting or permanent) effect during critical periods of development but can also impart (temporary or reversible) activational effects. Furthermore, males and females also carry different sex chromosome complements (SCC:XY/XX) and thus are influenced throughout life by different genomes. Previous evidence demonstrates a modulating effect of SCC in RAS receptor expression (at brain and renal levels), as well as in the AngII sexually dimorphic bradycardic barroreflex and hypertensive responses.

In the present study we evaluated the involvement of SCC and the organizational hormonal effect on changes in mean arterial pressure (MAP) in a 30 min Ang II infusion protocol. We also analized in a separate group of mice the activational estradiol effect. For this purpose, we used gonadectomized mice of the “four core genotype” model, in which the effect of gonadal sex and SCC is dissociated, allowing comparisons of sexually dimorphic traits between XX and XY females as well as in XX and XY males. For hormonal replacement experiments gonadectomized mice were daily injected with ß-estradiol (2ug/g) for a 4 day period.

The statistical analysis indicated that XX-male-CON, XY-female-CON and XX-female-CON showed an increase MAP due to AngII infusion, while no changes were observed in XY-males-CON mice suggesting an interaction of SCC and organizational-sex factors {F(1.25)=7.93;p<0.01}. Furthermore, this increase was reversed by the activational effect of ß-estradiol (CON vs.E2 {F(1.59)=8.73;p<0.01}) in XY-female and XX-male E2 groups. Our results thus suggest an interaction of SCC, organizational and activational ß-estradiol effect on angiotensin mediated blood pressure regulation

(1649) **VALPROATE (VPA), A HISTONE DEACETYLASE (HDAC) INHIBITOR, DECREASES FIBROSIS IN THE HYPERTROPHYC HEART OF SHR: TRH GENE EXPRESSION**

Ludmila Peres Diaz (1), Maria Landa (1), Maia Aisicovich (1), Mariano Schuman (1), Jorge Toblli (2), Silvia García (1), Carlos Jose Pirola (1)

National Scientific and Technical Research Council (CONICET), University of Buenos Aires Laboratory of Molecular Cardiology, -Institute of Medical Research (IDIM), Buenos Aires, Argentina. (2) Laboratory of Experimental Medicine, Hospital Aleman, Buenos Aires, Argentina.

Cardiac TRH induces hypertrophy (LVH) and fibrosis in normal rats. Also, cardiac TRH system is overexpressed in SHR. It´s known that the histone deacetylase families, which modify the access of transcription factors to DNA, affect cardiac hypertrophy in animal models. As VPA is an inhibitor of HDACs and modulates gene expression through epigenetic alterations such as DNA methylation, we hypothesized that inhibition of HDACs with VPA might attenuate LVH and the fibrotic process in SHR by modulating cardiac TRH gene expression. 7 w-old male SHR and WKY received VPA. Blood

pressure (BP) was recorded; after 10w of treatment rats were euthanized and hearts obtained. BP, LVH index and cTRH expression were increased in SHR vs WKY. VPA slightly attenuated (ANOVA,$p<0.05$) the higher BP (mmHg) seen in untreated SHR, without effect in WKY (**WKY**= C:128±4 vs VPA:126±3 and **SHR**=C220±4 vs VPA201±4). Hypertrophic index (HW/BW*100) was reduced ($p<0.05$) only in SHR (C:0.4516±0.02 vs VPA:0.3950±0.02). By ecocardiography we found a ($p<0.05$) reduction in LVPWT(mm) only in SHR (C:0.310±0.02 vs VPA:0.242±0.021). VPA normalizes ($p<0.05$) the higher expression of BNP and type 3 collagen in the LV of SHR indicating a strong reduction in fibrosis. This effect was confirmed by Masson's Trichrome and Sirius Red stainings ($p<0.01$). The higher TRH mRNA in SHR heart was reduce in the SHR+VPA to values similar to WKY (**WKY,**C:0.61±0.7vs VPA:0.41±0.97; **SHR,**C:5.72+0.9 vs VPA:0.61+0.9, $p<0.05$). Decreased TRH level by IHQ induced by HDAC inhibition confirms this result. Offspring born from VPA-treated parents with a 2-weeks washout period before mating, and which did not receive VPA ever, had a reduction of hypertrophy, fibrosis and cardiacTRH expression showing transgenerational inheritance. We described for the first time that VPA reduces fibrosis in an independent manner of LVH, effects inherited by the next generation. Our results strongly suggest that epigenetic TRH modulation may play a role.

REPRODUCTION AND FERTILITY 1

(772) AGING-ASSOCIATED INFLAMMATION IN TESTES OF SYRIAN HAMSTERS

Paula Valchi (1, 2), Ricardo Saúl Calandra (1), Mónica Beatriz Frungieri (1, 2), María Eugenia Matzkin (1, 3)

Abstract: Aging constitutes a universal, multi-factorial, progressive and irreversible process. Although the aging process may vary among different tissues, it is usually associated to a chronic inflammatory condition. Relevant to male reproductive aging, we have previously shown an inverse association between longevity and testicular pro-inflammatory state in mouse models with delayed (Ames dwarf Prop1$^{-/-}$ and growth hormone releasing hormone-knockout mice) or accelerated (growth hormone-transgenic mice) aging.

In this study, we analyzed testicular aging in a physiological animal model. To this aim, testes from young adults (5m: 5 months) and aged Syrian hamsters (20m-22m: 20-22 months) were used.

Immunohistochemical studies confirmed an aged-related significant increase in total numbers of Iba1-immunoreactive testicular macrophages (MAC) in which interstitial MACs solely accounted for the rise (Total testicular MAC/mm^2, 5m: 66.28±6.67^a; 20m: 110.00±10.00^b; 22m: 120.50±14.50^b; Mean±SEM, $p<0.05$). Testicular mRNA expression of cytokine IL1β, one of the main secretory products of MACs during inflammation, was found to be significantly higher in aged testes (5m: 1.00±0.05^a; 20m: 11.29±2.58^b; 22m: 16.56±1.80^b; $p<0.05$). Moreover, mRNA expression of cyclooxygenase 2 (COX2), a key enzyme in prostaglandin synthesis and a clear marker of inflammation, was also induced in an aged-dependent manner (5m: 1.00±0.16^a; 20m: 4.74±1.04^b; 22m: 3.47±0.96^b; $p<0.05$). A similar tendency was seen when testicular protein levels of IL1β and COX2 were evaluated.

Collectively these data suggest the development of a pro-inflammatory profile during physiological reproductive aging in the hamster testis.

(508) ENZYMES INVOLVED IN THE BIOSYNTHESIS OF THE VERY-LONG-CHAIN POLYUNSATURATED FATTY ACIDS OF RAT SPERMATOGENIC CELL SPHINGOLIPIDS

Florencia Ximena Santiago Valtierra (1, 2), Gerardo Martín Oresti (1, 2), Marta Isabel Aveldaño (1)

The sphingolipids (SL) of rodent germ cells contain very-long-chain polyunsaturated fatty acids (V), in nonhydroxy (n-V) and 2-hydroxy (h-V) forms, whose biosynthesis requires the expression of several elongases (Elovl) and a fatty acid 2-hydroxylase (Fa2h). Our objective was to characterize the expression of these enzymes as a function of postnatal development and germ cell differentiation. We employed qPCR for mRNA levels, Western blot and immunofluorescence for protein expression, and [^{3}H]-labeled precursors for enzyme activity. Elovl4, involved in C_{24}-C_{34} fatty acid biosynthesis, was expressed at the mRNA, but not at the protein level, at early prepuberal ages. Such mRNA was a product of Sertoli cells. Elovl4 mRNA *and* protein were both produced by germ cells. In agreement with the relative abundance of n-V in their SL, the Elovl4 enzymatic activity was higher in the premeiotic pachytene spermatocytes than in postmeiotic round and late spermatids ($p<0.05$), and was negligible in Sertoli cells. By contrast to *Elovl4* mRNA, that of *Fa2h* was absent from Sertoli cells and from prepuberal testes ($p<0.05$). *Fa2h* mRNA *and* protein were detectable only in concomitance with the appearance of spermatids, the sperm precursors whose SL are the richest in h-V. Consistently, selective depletion of germ (but not Sertoli) cells from adult rat testes by exposures to mild hyperthermia reduced the mRNA levels of *Fa2h* to a much larger extent ($p<0.001$) than that of *Elovl4.* Among germ cells of adult testes, Elovl4 protein content was high in spermatocytes and late spermatids, while Fa2h was mostly expressed in the latter, residual bodies and spermatozoa. By using inhibitors of specific steps of the SL biosynthetic route, germ cells in culture showed ability to *de novo* synthesize SL containing n-V and h-V. Our results underscore the presence of a developmentally programmed and a cell-specific regulation of the Elovl4 and Fa2h expression and activity as germ cell differentiation proceeds.

(1600) NONYLPHENOL INDUCES CYTOSKELETAL CHANGES AND RELEASE OF PROINFLAMMATORY MEDIATORS IN RAT SERTOLI CELLS *IN VITRO*

Ana Sofia Vallés (1), Rodrigo Godoy Sepúlveda (2), Gerardo Martín Oresti (1), Ricardo D. Moreno (3), Marta Isabel Aveldaño (1), Juan G Reyes (2)
(1) Instituto de Investigaciones Bioquímicas de Bahía Blanca (INIBIBB), Bahía Blanca, Argentina. (2) Instituto de Química, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile. (3) Departamento de Fisiología, Pontificia Universidad Católica de Chile, Santiago, Chile.

Nonylphenol (NP), an alkylphenol present in plasticizers, is an endocrine disrupting chemical that is potentially dangerous for male reproduction in mammals including man. Because Sertoli cells (SC) provide structural and metabolic support to germ cells, in this study the hypothesis that exposures of SC to NP affect their metabolic functions and the production of bioactive molecules was evaluated. Primary cultures of SC were preincubated with [^{3}H]arachidonic acid (AA) to label their lipids and then were treated with NP. The NP exposures resulted in increased concentrations of free AA in cells and medium, indicating that such AA was released from [^{3}H]-labeled lipids ($p<0.01$). This lipid was mostly phosphatidylinositol, acted upon after activation of a protein kinase A (PKA)/cytoplasmic phospholipase A2 (cPLA2). In NP-exposed SC, an increase of diacylglycerols (DAG) also took place in both, cells and medium ($p<0.01$). Part of such DAG may have served as second messengers, since NP-increased DAG were associated with an augmented production of PGE2 and expression (mRNA) of COX2. Since the network of vimentin intermediate filaments is important for intracellular lipid transport, the effects of NP on the structure of this network in relation to the formation of cytoplasmic lipid droplets (LD) was studied. In NP-treated SC, the vimentin network was redistributed and the LD size was increased. The NP-dependent cytoskeletal redistribution was prevented by preincubation with H89, a PKA inhibitor. The formation of large LD was prevented by preincubation with either H89 or MEP, a PLA2 inhibitor, suggesting the participation of PKA and cPLA2 in LD biogenesis. We conclude that NP is involved in

activating the proinflammatory pathway in SC, by providing the AA that is necessary for prostaglandin synthesis via PKA/PLA2 on the one hand, and by generating the DAG that is required as cofactor of the PKC-mediated activation of the NF- κβ/Cox-2 inflammatory pathway on the other.

(389) **PARTICIPATION OF SIRT1 IN THE REGULATION OF SERTOLI CELL PROLIFERATION**

Agostina Gorga, Gustavo Rindone, Mariana Regueira, Eliana Pellizzari, María Del Carmen Camberos, María Fernanda Riera, María Noel Galardo, Silvina Beatriz Meroni
Centro de Investigaciones Endocrinológicas "Dr. César Bergadá" (CEDIE) - CONICET - FEI - División de Endocrinología, Hospital de Niños "Ricardo Gutiérrez"

Abstract: Sertoli cells (SC) provide the structural and nutritional support for germ cell development. Considering that each SC is able to support a limited number of germ cells, the final number of SC reached during the proliferative periods determines sperm production capacity in adulthood. In the rat, SC proliferate during fetal and neonatal periods and it is well known that FSH is the major SC mitogen; however, little is known about the mechanisms involved in the detention of SC proliferation, essential for the formation of blood-testis barrier and SC differentiation. Sirtuins (SIRT1-7) belong to a cellular energy sensor family of NAD^+-dependent enzymes with deacetylase activity. SIRT1, the most studied member, plays an important role in several processes ranging from cell cycle regulation to energy homeostasis. The aim of this work was to investigate whether SIRT1 activation participates in the cessation of SC proliferation. Mitotically active SC obtained from 8-day old rats were maintained under basal (B) conditions or stimulated with FSH 100 ng/ml in the absence or presence of Resveratrol (RSV, 50μM) a polyphenol that increases SIRT1 activity. BrdU incorporation and the expression of cyclins D and p21 and p27 (cell cycle inhibitors) by RT-qPCR were evaluated. Results are expressed as mean±SD (n=3, different letters indicate statistically significant differences, P<0.05). RSV decreased BrdU incorporation under basal and FSH-stimulated cultures (B: 10.9 ± 1.9^a, RSV: 3.1 ± 1.3^b, FSH: 21.4 ± 3.2^c, FSH+RSV: 2.1 ± 2.3^b; %BrdU-positive cells) and inhibited the FSH effect on cyclin D1 and cyclin D2 expression. In addition, RSV increased p21 and p27 mRNA levels (p21: RSV: 3.3±1.1*; p27: RSV: 1.9±0.3*; fold stimulation vs B, *P<0.05). Altogether, these results suggest that SIRT1 activation may be involved in the cessation of SC proliferation through the regulation of cyclins and cell cycle inhibitors expression.

(1079) **PEDF (PIGMENT EPITHELIUM DERIVED FACTOR) EXPRESION IN MEPC5 CELLS (MOUSE) AND IN MALE REPRODUCTIVE TRACT (WISTAR RATS) UNDER ANDROGEN REGULATION**

María Inés Conte, María de los Ángeles Monclus, Miguel Walter Fornes
IHEM - Conicet - UNCuyo

Abstract: Pigment epithelium-derived factor (PEDF) expression has been described in many organs as showing neurotrophic, anti-angiogenic, anti-apoptotic, anti-inflammatory, anti-oxidant and pro-cell survival properties. However, references to its activity in the male reproductive system are scarce, except in prostate cancer and the regulation of sperm conjugation in rat epididymis. We aimed to characterize the expression of PEDF in MEPC5 cells (mouse epididymal proximal caput cells) and in the male reproductive tract of Wistar rats and explore their hormonal regulation. We found that PEDF is expressed in MEPC5 by Immunofluorescence and over the epididymis, prostate and seminal vesicles by immunohistochemistry, but notably not in the testes. These results agree with those obtain by semi cuantitative RT-PCR. Androgen dependence of PEDF expression was evaluated by flutamide administration during 15 days to Wistar Rats. PEDF expression diminished along the male reproductive tract. This decreased expression was reversed after 30 days without flutamide administration. The epididymis is an essential organ in sperm maturation-storage. The role of PEDF in this physiological process has not been fully elucidated. But considering that in other systems PEDF has anti-apoptotic, anti-oxidants and pro-cell survival properties, its expression along the epididymis may be related to the protection of spermatozoa while they are stored.

Keywords: PEDF, male reproductive tract, MEPC5 cells, androgens.

(162) **POSSIBLE ROL OF TESTICULAR TRANSFERRIN IN THE HOMEOSTASIS OF SEMINAL IRON**

Adriana Silvia Brufman (1), María Bucci Muñoz (1), Evangelina Vallejos (2), José Francisco Moreno (1), Nidia Mabel Abraham (1)
(1) Universidad Nacional de Rosario. Facultad de Ciencias Bioquímicas y Farmacéuticas. (2) Universidad de Morón. Licenciatura en Genética.

Testicular Transferrin (TTf) is a glycoprotein secreted by Sértoli cells and it is involved in the transport of iron to developing germ cells. Iron homeostasis is defined by mechanisms in which the intracellular concentration of this metal is maintained at adequate levels for cellular requirement but nothing enough to cause toxic effects. The study of DNA and sperm membrane (SM) plays a fundamental role in seminal evaluation. The aim of the present work is to investigate whether there is relationship between TTf levels and SM integrity and sperm DNA. Twenty semen samples were studied: 5 fertile controls (according to WHO 2010) and 15 from patients with different andrological pathologies. The variables studied were: Concentration of TTf versus % of spermatozoa with altered membrane and Concentration of TTf versus DNA integrity, among which the Pearson Correlation Coefficient was applied. The integrity of SM was evaluated by the Hypoosmotic Test (HOST). DNA integrity was assessed by the Acridine Orange Test (AOT). Determination of TTf levels was performed using the Radial Immunodiffusion method adapted for low concentration developed by our group. The relationships were as follows: 1) a high degree of negative association (r = - 0.91) was observed between TTf Concentration (mg / dL) and SM Integrity alterations (p <0.05). 2) no significant association was observed (r = 0.03) when studying the relationship between TTf concentration (mg / dL) and DNA integrity (p = 0.48). We conclude from these results that the low levels of TTf are associated with the loss of the integrity of the SM affecting its functionality while not with the integrity of DNA. The possible role of TTf as an antioxidant protein and its stabilizing function of the sperm membrane is postulated. It is necessary to analyze a great number of samples, to incorporate other techniques for the study of DNA and to study other functional parameters of semen and its relation with TTf.

Buenos Aires, Argentina.

The onset of spermatogenesis is androgen-dependant. Because germ cells do not express the androgen receptor (AR), Sertoli cells are believed to transduce testosterone (T) signals to them. This can only happen once AR expression in Sertoli cells begins around day 4. Expression of *Aldh1a1*, a retinoic acid (RA) synthesizing enzyme, is detectable by at least day 5 in Sertoli cells. RA induces expression of *Stra8*, which is associated with spermatogonial differentiation and

meiotic onset. In the *Aldh1a1*-null mouse testis, *Stra8* expression during the first wave of spermatogenesis is delayed. We hypothesise that androgens trigger the first wave of spermatogenesis by inducing the expression of ALDH1A1 in Sertoli cells of the pre-pubertal testis.

TM4 cells were treated with T (10^{-8} M) or vehicle and *Aldh1a1* expression was evaluated by qRT-PCR (**ΔΔ**Ct method, one sample t-test against 100% control, n=3 to 6). *Aldh1a1* was upregulated by a 1 h (*P*=0.013), 2 h (*P*=0.009), 4 h (*P*=0.018) or 8 h (*P*=0.036) treatment and was expressed at four-fold baseline levels (*P*=0.031) after 24 h. Treatment with the antiandrogen Bicalutamide reversed this upregulation. Bioinformatic analysis showed two putative androgen response elements upstream of the transcription start site and two within intron 1 of the *Aldh1a1* gene. Preliminary immunofluorescence results from pre-pubertal testis of RARE-*lacZ* reporter mice show co-localization of STRA8 and β-galactosidase (evidence for RA action) and weak expression of the AR in some Sertoli cell nuclei starting at 2 days. We conclude that androgens induce upregulation of *Aldh1a1* acting through the AR and that *Aldh1a1* upregulation might occur by both genomic and non-genomic mechanisms. Thus, testosterone may be important not just for the maintenance but also for the onset of spermatogenesis, acting via upregulation of ALDH1A1 in Sertoli cells.

(1186) **POTENCIAL PARTICIPATION OF PPARγ IN FSH REGULATION OF FATTY ACID STORAGE IN SERTOLI CELLS**

Mariana Regueira, Agostina Gorga, Gustavo Marcelo Rindone, María Noel Galardo, Eliana Herminia Pellizzari, María del Carmen Camberos, María Fernanda Riera, Silvina Beatriz Meroni

Centro de Investigaciones Endocrinológicas Dr. César Bergadá (CEDIE) División de Endocrinología, Hospital de Niños Ricardo Gutiérrez FEI CONICET

Abstract: Sertoli cells (SC) are necessary to provide an adequate and protected environment for germ cell development. Studies of SC glucose metabolism have shown that SC actively metabolize glucose but that the vast majority is converted to lactate that represents the preferential energy substrate for germ cells. In this metabolic scenario, fatty acids (FA) have been demonstrated to be needed to sustain SC energy status. The presence of numerous lipid droplets (LD) is characteristic in SC and it is assumed that they constitute the storage of these FA. In this context, we have demonstrated that FSH –the master hormone in the regulation of SC physiology– regulates LD content and the expression of the fatty acid transporter FAT/CD36 and of proteins that regulates LD formation and stability, PLIN1 and 2. On the other hand, we have also shown that pharmacological activation of PPARγ participates in the regulation of lipid storage in this cell type, although the participation of this transcription factor in hormonal regulation has not been analyzed yet in SC. The aim of this study was to analyze the potencial participation of PPARγ in FSH regulation of the expression of proteins involved in FA transport and storage. SC from 20-day old rats were used. Cultures were treated with FSH (100 ng/ml) in presence or absence of a PPARγ antagonist (T007; 50 μM). Results are expressed as mean±SD, n=3, different letters indicate statistically significant differences, p<0.05. PPARγ antagonist inhibited FSH stimulation of FAT/CD36 and PLIN1 expression (FAT: FSH: 3.2±02a; FSH+T007: 0.7±0.3b; PLIN1: FSH: 3.3±0.3a; FSH+T007: 0.3±0.2b fold-variation vs basal) and did not modify FSH-stimulated PLIN2 mRNA levels. These results suggest that in order to ensure the availability of FA for SC energetic requirements, FSH regulates lipid storage, at least in part, through PPARγ activation.

Keywords: Sertoli, Lipid Storage, FSH, PPARγ.

Abstract: Melatonin (mel) regulates testicular function acting indirectly through the hypothalamus/pituitary but also directly at the gonads. We previously quantified mel concentrations in testicular biopsies of patients suffering from hypospermatogenesis (H) or Sertoli cell only (SCO) syndrome. We also found that mel testicular concentrations negatively correlate with the number of local macrophages (MAC) and the gonadal expression of TNFα and IL1β.

This study attempted to evaluate the impact of oral mel supplementation in infertile patients. Men presenting idiopathic infertility and non-obstructive azoospermia without an infection process were assessed and diagnosed by open testicular biopsy. Biopsies were classified according to McLachlan et al. (*Human Reprod.* 2007). From medical records data we identified a group of patients that had been treated for sleeping disorders with a daily oral dose of 5 mg of mel.

In biopsies with H and SCO, testicular mel concentrations were markedly diminished while the numbers of testicular CD68–immunoreactive MACs and toluidine blue positive mast cells (MCs) were significantly increased compared with normal biopsies (p<0.05).

Mel consumption increased its own testicular levels (p<0.05) but did not affect the amount of gonadal MCs. However, the number of total (interstitial + tubular) CD68–immunoreactive MACs in patients taking mel was significantly lower than those detected in infertile patients and similar to those determined in normal biopsies (Total testicular MACs/mm^2, normal: 77,8±9,63^a, SCO: 473,4±97,0^b, SCO+mel: 137,8±33,3^{a,d}, H: 178,6±11,1^{c,d}, H+mel: 111,2±45,7^a; Media±SEM; p<0.05). In addition, TNFα and IL1β mRNA expression significantly increased in H and SCO compared to normal biopsies (p<0.05). On the other hand, mel intake in infertile men brings TNFα and IL1β mRNA expression closer to the normal range.

These results reveal that in infertile patients, mel intake is related to a *low*-grade testicular *inflammatory state.*

(1054) **THE NON-CLASSICAL ANDROGEN SIGNALING PATHWAY IS INVOLVED IN THE REGULATION OF *AMH* AND *CYP26B1* IN SMAT1 PRE-PUBERTAL SERTOLI CELLS**

Nadia Edelsztein (1, 2), Helena Schteingart (1), Rodolfo Rey (1, 3)

(1) Centro de Investigaciones Endocrinológicas Dr. César Bergadá (CEDIE) - CONICET - FEI, División de Endocrinología, Hospital de Niños Ricardo Gutiérrez. Buenos Aires, Argentina, (2) Dpto. de Ecología, Genética y Evolución, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires. Buenos Aires, Argentina, (3) Dpto. de Biología Celular, Histología, Embriología y Genética, Facultad de Medicina, Universidad de Buenos Aires. Buenos Aires, Argentina.

Testosterone acts through the androgen receptor (AR) in Sertoli cells to induce their maturation and support spermatogenesis, but the molecular and cellular mechanisms are still poorly understood. We have previously demonstrated that, in the pre-pubertal Sertoli cell line SMAT1, androgens exert a direct effect through the AR on two genes associated with Sertoli cell maturation: *Amh* - by inhibiting its expression – and *Cyp26b1* – by upregulating its expression - (Edelsztein *et al.*, SAIC 2015, 2016). Since the AR can act through classical (genomic) or non-classical (non-genomic) pathways, we sought to elucidate whether the effect of androgens on *Amh* and *Cyp26b1* gene expression occur through the classi-

cal, the non-classical or both pathways in Sertoli cells. SMAT1 cells were co-transfected with expression vectors for mutant AR proteins that selectively activate either the classical (ARΔ372-385) or the non-classical (ARC562G) testosterone signaling pathway together with *Amh or Cyp26b1* promoter luciferase constructs. SMAT1 cells were incubated with DHT (10^{-7}M) or vehicle for 24 h. Results, expressed as percentage (mean±SEM), are compared against basal activity (theoretical value: 100%) using a one sample t-test. *Amh* expression was inhibited when the ARC562G construct was present (62.9±7.864, *P*=0.042, n=3) but not after transfection of ARΔ372-385 (82.58±11.63, *P*=0.273, n=3). *Cyp26b1* expression was upregulated by the ARC562G construct (224.2±18.59, *P*=0.001, n=6) but not by ARΔ372-385 (103.6±7.451, *P*=0.647, n=6). We conclude that the non-classical pathway participates in the regulation of both *Amh* and *Cyp26b1* in SMAT1 cells, and could be involved in the maturation of Sertoli cells around the onset of puberty.

Keywords: Amh, *Cyp26b1*, Sertoli cell, androgens, non-classical pathway

(335) ANTI-ADIPOGENIC EFFECT OF THE ANTIOXIDANT N-ACETYLCYSTEINE ON 3T3-L1 ADIPOCYTES

Azul Pieralisi (1), Daniela Soto (1), Claudia Noemi Martini (1), Matías Gabrielli (1), María C Vila (2), Romina Mitarotonda (3), Mauricio De Marzi (3), Juan Carlos Calvo (1), Liliana Noemi Guerra (1, 2, 3)

Universidad de Buenos Aires, Facultad de Ciencias Exactas y Naturales, Departamento de Química Biológica, Buenos Aires, Argentine Republic. (2) CONICET - IQUIBICEN, Buenos Aires, Argentine Republic. (3) Universidad Nacional de Lujan, Departamento de Ciencias Básicas; CONICET - INEDES, Buenos Aires, Argentine Republic.

Reports about antioxidant effect on obesity are controversial. We showed that N-acetylcysteine (NAC) inhibits cellular lipid accumulation during 3T3-L1 adipocyte differentiation, through the inhibition of adipogenic transcription factors expression, such as PPARγ and, MAPK phosphorylation (Soto el al, Redox Rep 2016). Objectives: Here, we evaluated NAC effect on fully differentiated 3T3-L1 adipocytes (AC) and developed nanoparticles with NAC. Methods: Assays were conducted using AC, different doses of NAC (0.01 to 5 mM) were added to culture media for 5 days and, we determined: cellular content of triglycerides (Tg) and Oil-Red-O stained lipids (ORO), NAC toxicity by MTT assay, PPARγ protein expression by western blot assay, mRNA levels of PPARγ and lipid protein perilipin (Pl) by RT-qPCR analysis. NAC content in nanoparticles was determined by Raggi method. Results: Treatments with 0.01 to 5 mM NAC were not toxic on AC. 5mM NAC treatment on AC (ACN) elicited a 60% decrease in cellular Tg content (1.22±0.09 gTg/g protein [AC] vs 0.49±0.03 gTg/g protein [ACN], p<0.05). We evaluated ORO content in ACN compared to AC, which is set to 100 (100±4 [AC] vs 80±2 [ACN] arbitrary units (AU), p< 0.05), mRNA levels of Pl (Pl/ Rplp0:100±13 [AC] vs 72±9 [ACN] AU, p< 0.05) and, expression of PPARγ protein (PPARγ/GAPDH:100±6 [AC] vs 70±4 [ACN] AU; p< 0.05) and mRNA (PPARγ/Rplp0:100±7 [AC] vs 74±14 [ACN] AU, p<0.05). We developed silica hollow nanoparticles (100nm diameter, Nano) including 5mM NAC, as a better tool for NAC administration. We evaluated 5 different Nano preparations; our results showed a maximum of 13.2% incorporation of the total NAC. Conclusions: 5 mM NAC treatment on AC produced an effectively decrease in Tg content, and 20-30% decrease in ORO, Pl and PPARγ cellular contents. These results suggest that NAC could inhibit new lipid production in adipocytes. We also developed nanoparticles with NAC to use on AC.

Key words: adipocytes, antioxidant, obesity

(1588) ARTIFICIAL PANCREAS: RESULTS OF THE FIRST CLINICAL TRIAL IN LATIN AMERICA WITH AN ARGENTINEAN ALGORITHM

Ventura Alejandro Simonovich (1), Luis Alberto Grosembacher (1), Waldo Horacio Belloso (1), Maria Valeria Beruto (1), Paula Scibona (1), Javier Giunta (1), Cintia Rodriguez (1), Patricio Colmegna (2), Hernán Debattista (3), Fabricio Garelli (3), Daniel Cherñavvsky (4), Marcela Moscoso Vazquez (5), Demian García Violini (5), Emi Fushimi (3), Ricardo Sánchez Peña (5)

An Artificial Pancreas is a system by which a Continuous Subcutaneous Insulin Infusion (CSII) and a continuous glucose monitoring (CGM) are connected by bluetooth to a smartphone in which a control algorithm is programmed. This software receives glucose values and decides the insulin infusion rate to maintain normoglycaemia, creating a closed loop (CL) system.

The first algorithm developed in Latin America -ARG Algorithm- was tested in 5 adult patients with T1DM. ARG only required that meals were announced to the system but did not need to be informed of carbohydrates quantity.The Primary Outcome was to determine the percentage of time in which the system was connected and operating adequately. Secondary outcome measures were the percentage of time in which patients achieved desirable glycemia (70-180 mg/dl) and acceptable glycemia (180-250 mg/dl), as well as number of nocturnal or severe hypoglycemia.

Patients completed a 3 days run in period in which they used a sensor-augmented insulin pump in their everyday life. In order to test the CL system, patients were admitted for 36 hours at the Hospital Italiano de Buenos Aires, in which the first 21 hours were dedicated to calibrate the system and in the remaining 15 hours the system automatically regulated blood glucose.

All 5 patients remained in CL in adequate operation for 99.6% for 15 hours. The mean percentages of time in CL with glycaemia between 70-250 mg/dl was 94.66% [83.81, 98.38]; between 70-180 mg/dl was 82.55% [69.88, 95.22]; <70 mg/dl was 4.11% [0.83, 17.95]; and <50 mg/dl was 0.22% [0.01, 3.47], all with IC 95%. One mild nocturnal hypoglycemia occurred. No severe hypoglycemia occurred. No serious adverse events were reported.

It is peremptory to empower patients with chronic diseases. Developing algorithms such as the ARG algorithm, with promising initial results, contributes to this aim. However, further trials are needed to establish the safety and efficacy of the ARG algorithm.

(689) CHRONIC ENDOGENOUS GLUCOCORTICOID EXCESS AND WHITE ADIPOSE TISSUE BROWNING

Florencia Magalí Martín (1, 2), Eduardo Julio Spinedi (1), Andres Giovambattista (2)

(1) CENEXA. (2) IMBICE.

Glucocorticoids (GC) have different effects on white adipose tissue (WAT) and inhibit brown adipose tissue (BAT) thermogenesis; however, whether GC affects browning or not remains unclear. Our aim was to study the effect of chronic endogenous GC excess on browning activity of epididymal WAT (eWAT) stromal vascular fraction cells (SVFs) from 90 day-old, neonatally-treated, monosodium L-glutamate (MSG) male S-D rats. MSG and litter-mate controls (CTR) eWAT pads were dissected and processed for histological appearance and mRNA (qPCR) analysis. Then, isolated eWAT SVFs were processed for gene expression analysis or cultured up to reach confluence. Confluent cells were 3 day-differentiated with a classical pro-browning cocktail. On differentiation day 8, cells were stimulated with 10μM forskolin (4 h) or not, and cell UCP1 mRNA levels were quantified. Body weight and food intake were lower (p<0.05) in MSG rats, although eWAT mass was higher (p<0.05) and contained larger (p<0.01) adipocytes. Insulin, corticosterone (B), leptin and triglyceride plasma levels were high (p<0.01) in MSG rats. Remarkably, MSG eWAT pads showed low (p<0.05) mineralocorticoid and glucocorticoid receptor (MR and GR, respectively) gene expression levels. Interestingly, beige adipocyte markers (Cidea and PRDM16) were noticed in MSG eWAT and SVFs only. Differentiated MSG SVFs showed higher (p<0.01 vs. CTR) UCP1 expression levels before been stimulated (basal), although once stimulated with forskolin

both cells groups developed a significant ($p<0.05$ vs. basal values) increase in UCP1 mRNA levels, although being both similar among them. Altogether our data are highly indicative for a GC-resistance developed by MSG rats (decreased eWAT, MR/GR mRNAs and high plasma B levels). We conclude that the beige adipocyte lineage could be favored due to the lack of a full GC inhibitory effect on MSG SVFs. (FPREDM052015; PICT-2013-0930)

(1715) **DIABETIC ENVIRONMENT INFLUENCES THE BASAL CONDITION OF DENTAL PULP PROGENITOR CELLS**

Maria Virginia Gangoiti, Ana Maria Cortizo
LIOMM-Fac Cs Exactas-UNLP

Our objective was to characterize the basal state of the progenitor cells from dental pulp (DPPC) of control rats (C) and with diabetes mellitus (D). Adult Wistar rats injected with streptozotocin and nicotinamide (model of diabetes with partial insulin deficiency) or untreated (control) were used. The DPPCs were extracted from the dental pulp of the lower incisors of both experimental groups and were maintained in DMEM-10% fetal bovine serum at 37 °C and 5% CO_2. Once the cells reached semi-confluence, proliferation capacity (violet crystal bioassay), actin cytoskeleton distribution (Alexa fluor-phalloidin) and expression of osteogenic (Runx2), adipogenic transcription factors ($PPAR\gamma$) as well as inflammation markers (HMGB1, IL1) and the receptor RAGE by RT-PCR were evaluated. DPPC-C proliferated linearly during one week of culture, while DPPC-D showed a significant decrease in the ability to proliferate at the end of that period ($p<0.05$). On the other hand, the DPPC-D showed a reorganization of the actin filaments with thicker and isolated fibers, compared to the actin network of the DPPC-C. In addition, DPPC-D expressed approximately 16 times more $PPAR\gamma$ than DDPC-C, which in turn expressed 14 times more Runx 2 than DPPC-D. This finding was accompanied by an increase in the expression of inflammatory markers such as HMGB1, IL1 and the receptor RAGE (15, 6 and 10 times respectively) in DPPC-D. According to our results, the DPPC-D have a marked inclination to the adipocytic phenotype and reflect the inflammatory condition associated with diabetes.

We conclude that the dental pulp represents an accessible and interesting source of adult mesenchymal stem cells, in which a diabetic environment can modulate its proliferative capacity as well as its phenotypic expression.

(1494) **EFFECTS OF MELATONIN TREATMENT ON INFLAMMATORY MARKERS AND PITUITARY DYSFUNCTION IN INSULIN RESISTANT RATS**

Juan Salvador Calanni (1), María Elisa Mercau (1), Morena Wiszniewski (1), Marcos Aranda (2), Silvia Sánchez Puch (1), Carolina Vecino (1), Esteban Martín Repetto (1), Cora Beatriz Cymeryng (1)
(1) Laboratorio de Endocrinología Molecular-CEFyBO. (2) Laboratorio de Retinoneurología y Oftalmología experimental-CEFyBO

Excessive consumption of diets with high sugar content has been associated with an increased incidence of insulin resistance and obesity. Several reports have shown a concomitant dysfunction of the hypothalamus pituitary adrenal (HPA) axis in these patients. We have previously reported that rats fed a sucrose rich diet (SRD, 30% sucrose in the drinking water) for 7 weeks show a significant decrease in insulin sensitivity. Analysis of HPA axis activity after 3 weeks of treatment, when changes in insulin sensitivity were still not evident, showed augmented levels of circulating ACTH and a higher pituitary expression of POMC that was accompanied by an increase in oxidative stress parameters.

Present experiments were designed to analyze the involvement of inflammation-related effects on the observed pituitary dysfunction. Animals were randomly distributed in 4 groups: 1) Control, 2) SRD, 3) Mel and 4) SRD + Mel. In groups 3 and 4, subcutaneous melatonin implants (10mg) were surgically implanted. Animals were sacrificed after 3 weeks and pituitary glands were processed to obtain protein and RNA.

Results showed an increase in mRNA levels of TNFα ($p<0.001$) and inflammasome components (ASC, NALP3, IL-1beta, $p<0.01$ *vs.* C) in the SRD group that was prevented by melatonin treatment. In addition, immunohistochemistry analysis of pituitary tissues indicated an increase in both ACTH and Iba1 positive signals in the SRD-group that were attenuated in the SRD-Mel group. Western blot studies also showed higher levels of the macrophage marker F4-80 in the SRD-group. In vitro studies, in the corticotroph AtT20 cell line, showed the induction of POMC by conditioned media obtained from peritoneal macrophages or from J774 cells stimulated with LPS.

In summary, our results suggest that changes in the synthesis and secretion of ACTH detected in SRD-treated rats could be involved the activation of inflammation-related pathways.

(572) **IMT504 INHIBITS INSULITIS AND LOWERS BLOOD GLUCOSE IN NOD/Ltj FEMALE MICE IN A SHORT-TERM TREATMENT**

Stefania Bianchi, Milena Massimino, Carlos Libertun, Maria Silvia Bianchi, Victoria Lux-Lantos
Institute of Biology and Experimental Medicine

Immunomodulatory oligonucleotide IMT504 (IMT) induced a marked recovery of glycemia, glucose clearence, insulin secretion and beta cell function (by HOMA beta cell index) on a spontaneous autoimmune diabetes model (in male and female NOD/Ltj mice).

We analyzed the minimun dose at which the IMT has an early effect on glycemic control and insulitis. Diabetic female NOD/LtJ mice (two consecutive non-fasted glycemia (Gly) levels ≥ 250 mg/dl) were treated with a daily dose of IMT for five days (IMT: 2, 6 or 20 mg/kg/day, IMT2, IMT6 and IMT20) or saline as control (DC). Mice were sacrificed the day following the last injection. In fasted conditions, blood samples and pancreases were obtained for Gly and insulinemia measurment and for histological studies respectively.

We observed that 12.5% (1/8) DC mice showed spontaneous reversion of diabetic condition, whereas IMT improved Gly in 62.5% (5/8), 50% (4/8) and 75% (6/8) of mice treated with 2, 6 and 20 mg/kg/day, respectively (X^2: DC vs IMT20: $p<0.025$).

Gly did not vary with time (day 6 vs day 1) in DC mice while it significantly diminished with IMT treatment [(mg/dl):interaction, $p<0.01$, DC: Day 1: 330 ± 71 vs Day 6: 333.± 118, IMT2: Day 1: 303 ± 49 vs Day 6: 233 ± 57, IMT6: Day 1: 283 ± 22 vs Day 6: 194 ± 44, IMT20: Day 1: 313 ± 42 vs Day 6: 147 ± 42, IMT20: Day 1 vs Day 6: $p<0.02$]. Body weights did not differ among groups. Fasted glycemia also diminshed significantly with IMT20 treatment (DC vs IMT20: $p<0.04$). Since IMT20 showed the most effective response, we analyzed insulitis in this group. Treated mice showed a marked reduction in leukocyte islet infiltration (insulitis index: DC: 0.66 ± 0.05 vs IMT20: 0.48 ± 0.05, $p<0.05$).

Taken together, these results demonstrate that IMT20 treatment promotes an early, significant improvement in the diabetic condition in NOD/Ltj mice warranting further investigation of its mechanism of action.

(264) **NARINGIN PREVENTS CHANGES IN THE MITOCHONDRIAL PHYSIOLOGY AND MORPHOLOGY OF KIDNEY IN THE EXPERIMENTAL DIABETES MELLITUS**

Adriana Del Valle Pérez (1), Maria Angelica Rivoira (1), Luis Mario Plavnik (2), Nori Tolosa De Talamoni (1)
(1) Bioquimica y Biologia Molecular, Fac. Cs. Medicas,UNC. (2) Histología A, Fac. de Odontología, UNC.

We have previously demonstrated that the Diabetes mellitus (Dm.) inhibits the intestinal Ca^{2+} absorption, which was accompanied by oxidative stress. Other studies in diabetic rats have shown

enhanced glomerular filtration rate with raised urinary output and reduced Ca2+ reabsorption. Alteration of the redox state was observed in kidney mitochondria, with reduced ATP synthesis, changes in calcium homeostasis and increased biogenesis. The objective of this study was to determine if naringin (NAR), a natural antioxidant, could block the alterations in the renal morphology, mitochondrial redox state and energy metabolism from kidney in diabetic rats. Adult male Wistar rats were divided in: 1) controls, 2) streptozotocin (STZ) treated (diabetic rats) and 3) STZ + NAR treated. Mitochondria were isolated from renal tissue from each group of animals by differential centrifugation. In the mitochondrial extracts the activities of the enzymes isocitrate dehydrogenase (ICDH-NAD), malate dehydrogenase (MDH-NAD), superoxide dismutase (SOD), catalase (CAT), glutathione (GSH) and superoxide anion levels (˙O2-) were determined by spectrophotometry. Kidney morphology was analyzed by histological studies. Results were assessed by one-way ANOVA and Bonferroni multiple comparison test. The STZ treatment decreased the enzymatic activities of ICDH and MDH and the GSH content, which were avoided by NAR. STZ increased the SOD and CAT activities and the contents of ˙O2- and protein carbonyl. All these effects were blocked by NAR, except CAT activity. In addition, diabetic rats showed disorganized glomeruli, which were smaller than those from controls. The epithelial cells from distal convoluted tubules were also decreased by STZ. All these morphological changes were avoided by NAR. In conclusion, NAR abrogates morphological alterations in the diabetic kidney and changes in the energy metabolism from the renal mitochondria improving the redox state of these organelles.

(029) **NARINGIN: AN ANTIOXIDANT THAT IMPROVES HEPATIC DAMAGE PRODUCED BY EXPERIMENTAL DIABETES MELLITUS**

Valeria Andrea Rodriguez (1), Luis Mario Plavnik (2), Nori Graciela Tolosa De Talamoni (1)
(1) Cátedra de Bioquimica y Biologia Molecular, Facultad de Ciencias Médicas, INICSA-UNC. (2) Cátedra de Histología A, Facultad de Odontología, UNC.

Hepatic injury is a major complication of Type 1 Diabetes mellitus (DM1). Since naringin (NA) is a flavonoid with antioxidant properties, it might reduce hepatic complications in DM1. The aim of this study was to know the effect of NA on hepatic oxidative/nitrosative stress and apoptosis in a model of DM1. Two-month male Wistar rats were used: a) controls, b) diabetic rats (induced by 60 mg/kg b.w. streptozotocin: STZ), and c) STZ+NA: diabetic rats treated with NA (40 mg/kg b.w.). Animals were sacrificed at 30 days post-treatment, and serum glucose, HbA_{1c}, insulin, triglycerides (TG), GOT and GPT were determined. Liver slices were stained with H&E for morphometric analyses. Total glutathione (GSH) content, superoxide anion ($^{\cdot}O_2^-$) levels and superoxide dismutase (SOD) and catalase (CAT) activities from rat liver were measured by spectrophotometry. Nitrosative stress was evaluated by nitric oxide (NO) and nitrotyrosine content and inducible nitric oxide synthase (iNOS) protein expression. Apoptosis was evaluated by counting apoptotic nuclei and Fas, FasL and Bax protein expression. Results were evaluated by ANOVA and Bonferroni test. STZ rats presented higher levels of glycemia, HbA_{1c}, TG, GOT and GPT, and lower insulin levels in relation to those from controls. Although NA treatment did not produce changes in glycemia, HbA_{1c} and insulin, it decreased the levels of TG and transaminases. The cytoplasmic and nuclear areas of the hepatocytes in the STZ rats were higher. STZ rats showed increased apoptotic nuclei and protein expression of molecules involved in apoptosis. STZ rats exhibited GSH depletion and increased $^{\cdot}O_2^-$ content and SOD and CAT activities. NA treatment normalized these parameters. NO content and iNOS protein expression were higher in STZ rats compared to controls, which were prevented by NA. In conclusion, NA would have the ability to prevent chronic liver injury triggered by DM1 due to its antioxidant, anti-nitrosative and antiapoptotic properties.

(153) **TYPE 2 DIABETES MELLITUS (DM2) INDUCED BY HIGH-FAT DIET (HFD) IN MICE ARE SENSITIZED TO DEN-INDUCED HEPATIC CARCINOGENESIS**

Ainelén Arboatti (1), Flavia Lambertucci (2), María Guillermina Sedlmeier (1), Gerardo Pisani (3), Juan Monti (3), Daniel Francés (1), María Teresa Ronco (1), Cristina E Carnovale (2)
(1) Instituto de Fisiología Experimental-CONICET-UNR. (2) Instituto de Fisiología Experimental-CONICET-FBioyF-UNR. (3) Area Morfología-FBioyF-UNR.

DM2 is the most common form of DM characterized by hyperglycemia, insulin resistance, and relative insulin deficiency. DM2 results from interaction between genetic, environmental and behavioral risk factors. Epidemiological studies indicate that DM2 is associated with increased risk of developing cancer. We study the liver sensitivity of DM2 (induced by HFD) to development of hepatocellular carcinoma (HCC) Therefore we have used the carcinogenic agent diethylnitrosamine (DEN), analyzing the proliferative process as early stage of hepatic carcinogenesis. Five-week-old mice C57BL/6 were randomly divided into 4 experimental groups: Control (C, mice were fed a normal chow diet), C treated with DEN (C+DEN), HFD mice that fed a high-fat diet and HFD+DEN animals that fed a high-fat diet and received DEN at 16 weeks (n=4 in each group). Mice were euthanized at 25 weeks after DEN-injection. In liver sections we performed histological studies and quantification of hepatocytes in the different phases of the cell cycle (immunohistochemistry of PCNA). HFD+DEN showed an increase in hepatocytes in phases G1, S and M as well as proliferative index (PI) compared to C ($p<0.05$). HFD+DEN showed an increase in hepatocytes in phase G1 (+138%$^{\#}$), in phase S (+123%$^{\#}$), in phase M (+510%$^{\#}$) and PI (hepatocytes in phase G1, S, G2 and M, +173%$^{\#}$) ($^{\#}p<0.05$ vs C+DEN) which would indicate a promotion in the cell cycle with an increase in phase M.These results are in coincidence with the increase observed in the expression of markers of cell cycle progression: cyc E1 (+25%$^{\#}$), cyc D1 (+51%$^{\#}$) and cyc G1 (+52%$^{\#}$) showing a cell cycle progression toward phase M. Vascular endothelial growth factor (VEGF), signaling protein produced by cells that stimulates angiogenesis, showed an increase in HFD+DEN (+76%$^{\#}$). These results suggest that at 25 weeks after DEN administration, cell environment is modified and allowed as to analyze proteins that increase sensitivity cancer develop in the liver diabetic state.

(541) **BOTH INDUCED HYPERURICAEMIA AND HIGH FRUCTOSE DIET CONDITIONS INDUCE CARDIAC MORPHOLOGICAL CHANGES ASSOCIATED TO HYPERTENSION IN MALE RATS.**

Maria Jimena Soutelo (1), Yanina Alejandra Samaniego (1), Maria Cecilia Fornari (2), Carlos Reyes Toso (3), Osvaldo Juan Ponzo (1)
(1) Laboratorio de Endocrinología - Dpto. de Fisiología. Facultad de Medicina. UBA. (2) Laboratorio de Análisis Clínicos Bioalpha-Fornari. (3) Departamento de Ciencias Fisiológicas, UAII, Facultad de Medicina, UBA.

We have demonstrated that high-fructose diet intake and induced hyperuricemia increase Systolic blood pressure (SBP) separately or together. Objective: to evaluate the effect of these metabolic conditions on cardiac morphological changes. Material and Methods: Adult male Wistar rats (*n*=7/group), were divided into four groups receiving during 5 weeks: a) Control (C): standard commercial diet and water, b) Fructose (F): control diet plus 10% fructose in the drinking water, c) Oxonic acid (OA): control diet and water plus the uricase inhibitor OA (750 mg/kg/d), d) Fructose and Oxonic Acid (FOA): control diet with 10% (w/v) fructose in the drinking water plus oxonic acid. Plasmatic creatinine, uric acid and total-cholesterol (TC), triglycerides (TG), HDL-cholesterol (HDL) and TG/HDL were measured. Myocyte morphometric analysis (H&E and PAS), was done measure cardiomyocyte volume, calculated from individual myocyte area (length (µm) x width (µm) x 7.59 x 10-3), and the study of fibrosis (Masson's trichrome). Statistical analysis by two-way ANOVA and Bonferroni post test was performed (significant $p<0.05$). Results: Plasmatic uric acid levels were significantly higher in animals treated with OA (1.28±0.14, $p<0.05$) and FOA (1.49±0.1,

p<0.01) when comparing to the control (0.97±0.04). There were no differences in all lipid profile between different experimental groups. Myocyte size was higher in FOA (59.37± 4.68 pL, p<0.001), followed by OA (52.86±3.10pL, p<0.001) and F group (42.18± 2.00 pL, p<0.05) vs C (30.15±1.47 pL) group. The percentage of cardiac fibrosis was greater in FOA (3.43±0.14 p<0,009) and in F (3.25±0.14 p<0.03) vs control (2.69 ±0.196) groups.

Conclusion: Hyperuricemia and high-fructose diet conditions, in addition to increase SBP, cause morphological changes in the cardiomyocyte translated as cellular volume and fibrosis increase, being these effects more relevant in animals with both conditions simultaneously (FOA).

Key Words: hyperuricaemia, metabolic syndrome, rats, cardiac morphology, fructose diet

(1505) AQUAPORIN-2 IN THE ADENINE-INDUCED CHRONIC KIDNEY DISEASE MODEL

Lucas Oronel (1), Maria Del Carmen Ortiz (1), Milena Palamidessi (1), Carolina Yarza (1), Rocio Marinoni (1), Monica Majowicz (1), Maria Florencia Albertoni Borghese (1,2)

(1) Catedra de Biologia Celular y Molecular, Facultad de Farmacia y Bioquimica, Universidad de Buenos Aires. (2) CONICET

Chronic kidney disease (CKD) is one of the leading sanitary problems in Argentine. Recently, vasopressin (VP), the main regulator of Aquaporin-2 (AQP2) expression, was suggested as a contributor to the development of CKD. However, the mechanisms of VP contribution remains unknown.

The aim of this work was to characterize a new model of CKD and evaluate AQP2 expression in renal medulla.

Materials and methods: Male SD rats were treated for 2 weeks with an adenine rich diet (ERC group n=4; 0.25% adenine in standard rat chow powder). Control group received standard rat chow powder (C group n=4).

After 2 weeks, animals were kept in metabolic cages to collect 24 h urine. Blood samples were obtained, the kidneys were removed and weighed and processed for further determinations.

Determinations: Plasmatic (P) and urinary (U) urea, P and U creatinine, diuresis, AQP2 protein expression by WB and immunohistochemistry and AQP2 mRNA expression by real time PCR.

Results were expressed as media ± SEM and T-test was performed.

Renal weight/100g bw.: C: 0.35 ± 0.01 vs CKD: 0.45 ± 0.02 g (p< 0,005); P urea (mg/dl): C: 77.82 ± 1.49 vs. CKD: 110.50 ± 9.73 (p<0,05); U urea (g/L): C: 41.90 ± 1.53 vs CKD: 60.10 ± 4.73 (p<0,05); P creatinine (mg/dl): C: 0.57 ± 0.01 vs CKD: 0.89 ± 0.05 (p< 0,005); U creatinine (g/24h): C: 0.017 ± 0.001 vs CKD: 0.019 ± 0.015 (ns); creatinine clearance (ml/min): C: 2.06 ± 0.18 vs CKD: 1.50 ± 0.05 (p<0.05); Diuresis (ml/24 hs): C: 10.8 ± 3.2 vs CKD: 14.3 ± 3.8 (ns); AQP2 expression (WB): C: 1.00 ± 0.18 vs CKD: 1.74 ± 0.18 (p<0.05); mRNA AQP2 expression (fold change from C): C: 1.11 ± 0.29 vs CKD: 1.14 ± 0.22 (ns).

Adenine administration for two weeks resulted in an adequate model for CKD showing increased levels of plasmatic urea and creatinine. AQP2 expression (evaluated by WB and Immunohistochemistry) significantly increased in the renal medulla, suggesting that this could be at least one of the mechanisms by which VP is involved in the development of CKD.

Key words: chronic kidney disease, adenine, AQP2, vasopressin

(1126) CHRONIC NEPHROPATHY IN RATS SURVIVING HEMOLYTIC UREMIC SYNDROME

Federico Claudio Ochoa (1), Abril Seyahian (1), Cristian Costales Collaguaso (1), Azul Selene Diaz (1), Aldana Iaria (1), Leandro Maximiliano Maiolo (2), Leticia Bentancor (3), Nestor Lago (4), Elsa Zotta (1)

Hemolytic uremic syndrome (HUS) is a thrombotic microangiopathy associated with Shiga toxin-producing E. *coli* (STEC). Its clinical features are hemolytic anemia, thrombocytopenia and renal failure. HUS is the most frequent cause of renal failure in children. After the acute episode 25% of children suffer from some degree of reduced renal function. Our aim is to characterize the physiopathological factors related with evolution of renal injury to chronicity in a HUS model in rats.

Adult male Sprague-Dawley rats (200g) were randomly divided into two groups and injected intraperitoneally with culture supernatant of recombinant E.*coli* DH5α, either expressing Stx2 (experimental group) or not expressing Stx2 (control group). In the experimental group, half of the animals received enalapril (50mg/kg) in drinking water while other half received no medication. Rats were sacrificed at 1 week and 12 weeks. Functional, histological, immune histochemical and molecular studies were performed in all groups.

The functional studies showed a decreased GFR at 1 week with no significant variation at 12 weeks while proteinuria and microalbuminuria are increased at 12 weeks. At this time we also found significant cortex and medullar fibrosis. These histological findings correlate with immunohistochemically stain of TGF-β.

In order to check the presence of the toxin in renal tissues, we performed an immunohistochemistry study and we observed the expression of Stx2 at 1 week and 12 weeks. At last time the expression was strong at medullar level. We detected the presence of bacterial Phage on kidney tissue with same pattern as the toxin, fibrosis and TGF- β expression.

Our results suggest the possibility of the internalization of phage DNA in eukaryotic cells which is capable to produce more toxin and could maintain the lesional renal mechanism to chronicity

(5) Cátedra de Química Biológica, Facultad de Farmacia y Bioquímica (FFyB), UBA. (6) Hospital Alemán.

The aim of this study was to evaluate the effects of a low dose of angiotensin II (ANG II: 1 ug/kg/hour) on renal dopaminergis system (RDS) through determination of the organic cation transporters (OCTs and OCTNs) expression in renal cortex, dopamine (DA) urinary levels, Na+,K+–ATPasa (NKA) activity and renal function. Under inhibition of DA synthesis by benserazide, anesthetized male Sprague Dawley rats were infused with isotonic saline solution during 120 minutes and randomized in nine different groups: control, pargyline plus tolcapone (P+T), ANG II, DA, ANG II+DA, D-22, ANG II+D-22, DA+D-22 and ANG II+DA+D-22. Renal functional parameters and direct blood pressure were determined and urinary DA concentration was quantified by HPLC. Expression of OCTs, OCTNs, D1-subtype receptor (D1R) and NKA in membrane preparations from renal cortex tissues were determined by Western Blot. NKA activity was determined using in vitro enzyme assay. Compared to P+T group, DA infusion significantly increased fractional excretion of sodium (FENa) and DA excretion (*: p<0,05). These effects were not

observed with ANG II infusion except in ANG II+DA group versus DA group for FENa values after 120 minutes of infusion (*). OCTs blockade by D-22, reversed DA-dependent natriuresis demonstrating that OCTs are implied in DA uptake and transport in renal tissues. The activity of NKA was greater in ANG II groups versus respective animals without ANG II (*). OCTs, D1R, NKA and phosphorilated NKA protein expression were not modified by ANG II infusion. Urinary DA concentration was not altered in ANG II+DA rats versus DA alone group. This result is consistent with the fact that total OCTNs expression was not affected by ANG II, despite obtaining significant augmentation (*) of OCTN-1 expression versus P+T rats. To conclude, ANG II modifies the activity of NKA, the final effector of DA-D1R pathway, without affecting RDS.

Keywords: angiotensin II, organic cation transporters, renal cortex, dopamine, Na^+,K^+–ATPasa

(1243) **FOCAL ADHESION ASSEMBLY/DISASSEMBLY AND TRPV4 PARTICIPATION IN AQP2-DEPENDENT RENAL CELL MIGRATION**

Alan White, Alejandro Pizzoni, Valeria Rivarola, Natalia Beltramone, Paula Ford, Claudia Capurro, Gisela Di Giusto
Laboratorio de Biomembranas, IFIBIO HOUSSAY, Fac. de Medicina, CONICET-UBA.

We have previously demonstrated that Aquaporin 2 (AQP2) promotes renal cell migration. It is well known that migration is a process that requires continuous turnover of focal adhesions (FAs) and it was shown that AQP2 interacts with proteins forming FAs, so the aim of the present work was to study the dynamics of FAs in renal cells expressing AQP2. Moreover, since Ca^{2+} signaling is implicated in FAs turnover and results from our laboratory showed a differential activation of the Ca^{2+} channel TRPV4 influenced by AQP2, we also investigated if TRPV4 participates in the AQP2-enhanced renal cell migration. For experimental procedures two renal cell lines were used: WT-$RCCD_1$ (not expressing AQPs) and AQP2-$RCCD_1$ (transfected with AQP2). Immunofluorescence studies with paxillin were performed in scratched monolayers to visualize FAs. Images were taken with a confocal microscope, deconvolved and processed for making FAs area measurements. Cell migration in presence of TRPV4 agonists 4α-PDD (10 μM) and GSK1016790A (3 nM) was investigated with Wound Healing assay. Images were taken at different times and results were expressed as % of wound closure. Immunofluorescence studies showed punctuated paxillin labeling indicating FAs in the leading edge of migrating $RCCD_1$ cells. These FAs were found to be small in AQP2-$RCCD_1$ (1.80±0.19 mm^2, n=85) than in WT-$RCCD_1$ (5.87±1.04 mm^2, n=120, $p<0.05$). Wounding assay with TRPV4 agonists showed that the % of wound closure was diminished in AQP2-expressing cells (4α-PDD: n=15, $p<0.001$ and GSK: n=14, $p<0.001$). In summary, since actively migrating cells typically exhibit nascent small FAs and, conversely, larger FAs indicate more resistive forces to migration, our results could provide an explanation for the increased migration observed in AQP2-$RCCD_1$, revealing a rapid assembly/disassembly of FAs. On the other side, results about TRPV4 activation wouldn't be indicating, at first glance, its involvement in the AQP2-enhanced renal cell migration.

Keywords: AQP2, renal cell migration, focal adhesions, TRPV4

(1014) **IN VITRO STUDIES OF THE RENAL EXPRESSION OF CAVEOLIN 1 AND 2 IN EXTRAHEPATIC CHOLESTASIS.**

Evangelina C. Nosetto, Romina V. Campagno, Adriana M. Torres, Anabel Brandoni
Área Farmacología. Facultad de Ciencias Bioquímicas y Farmacéuticas. Universidad Nacional de Rosario. CONICET.

Caveolins, Cav1 and Cav2, are integral membrane proteins present in caveolae, a subtype of lipid raft, flask-shaped and enriched of cholesterol and sphingolipids. Caveolins participate in diverse biological processes, such as signal transduction and vesicular trafficking. In addition, they act as regulators of a wide variety of proteins. So far, little is known about renal expression of Cav1 and Cav2 under pathological conditions, particularly in obstructive cholestasis. The aim of this work was to perform *in vitro* studies in order to evaluate the renal expression of Cav1 and Cav2 in extrahepatic cholestasis. Suspensions of rat renal proximal tubule cells were obtained, and incubated for 3 h with serum from Sham-operated rats (S) or from rats with bile duct ligation of 72 h (L). All incubations were performed at 37°C with constant agitation and exposition to 95% O_2–5% CO_2. Cell viability was assessed by exclusion of trypan blue. Viability of the original suspension was approximately 93%. Cell viability (%) did not change independently of the tested treatments (S=91±3 (n=5), L=89±3 (n=8)). Cell homogenates (H) and cell membranes (M) were then prepared and assayed for Cav1 and Cav2 protein expression by electrophoresis and Western Blotting. Results: mean±SEM. Cav1 (%): H: (S)=100±3 (L)=78±4* M: (S)=100±4 (L)=86±3*. Cav2 (%): H: (S)=100±3 (L)=84±4* M: (S)=100±3 (L)=82±5* (*p<0,05). Some components present in L serum may lead to reduce Cav1 and Cav2 expression through a decrease in their synthesis or an increase in their degradation. Cav1 and Cav2 have been reported to participate in the modulation of organic anions transporters (Oat) 1 and 3 located at the basolateral membrane of tubular renal cells. We have described altered expression of both Oat1 and Oat3 in extrahepatic cholestasis of 72 h. The decreased expression of caveolins observed in this study, may be influencing the expression and function of these relevant transporters in extrahepatic cholestasis.

Keywords: Caveolins, kidney, cholestasis.

(1540) **ROLE OF TRPV4 AND AQP2 EXPRESSION IN RENAL CORTICAL COLLECTING TUBULE CELL GROWTH IN ACIDOSIS.**

Micaela Porta (Marina Mazzocchi, Gisela Di Giusto, Alejandro Pizzoni, Natalia Beltramone, Paula Ford, Claudia Capurro, Valeria Rivarola
Universidad de Buenos Aires. Facultad de Medicina. Departamento de Fisiología. Laboratorio de Biomembranas. Buenos Aires, Argentina. CONICET-Universidad de Buenos Aires. Instituto de Fisiología y Biofísica "Bernardo Houssay" IFIBIO-HOUSSAY. Buenos Aires, Argentina.

As mechanisms of proliferation and intracellular pHi are associated is possible that a chronic alteration of the pH modifies cell growth. We previously showed in renal cells that aquaporin 2 water channel (AQP2) expression prevents inhibition of cell growth in acidic media. Ca^{2+} channel TRPV4 has been proposed as one possible acid sensor. Our previous work showed that TRPV4 and AQP2 interact. So, the aim of this study was to investigate whether renal cell growth in acidic media was dependent on TRPV4. To investigate this we used two renal cortical collecting duct cell lines: WT-$RCCD_1$, not expressing AQPs, and AQP2-$RCCD_1$ expressing constitutive AQP2 in the apical membrane. Cell Growth studies (CG) were performed in control and acid media in presence of vehicle or the TRPV4 inhibitor Rutenium Red (RR). At physiological pH inhibition of TRPV4 decreased both lines cell growth about 20%. .After 24h exposure to an acidic media (ΔpH = 0.4) only WT cells decreased its growth and this response was not modified by RR (%CG Acid = -32±7 vs Acid + RR= -37±9, ns n=18). On the other hand, while acid media did not alter AQP2 expressing growth acid + RR significantly decreased cell growth (%CG Acid =-3±4 vs Acid + RR= -51±15, $p<0.01$ n=17). These results demonstrate that to prevent acidic cell growth inhibition AQP2 is associated to TRPV4 channel.

KEYWORDS: KIDNEY, ACIDOSIS, TRPV4, AQP2

(1555) **EXPRESSION OF APELIN mRNA IN THE POST-ISCHEMIC RAT KIDNEY**

Sara M Molinas (1,2), Zoe Sabariz (1), Emilse Weihmüller (1), Susana Marquez (3), Laura Trumper (1,4), Liliana A Monasterolo (1,2,4)
(1) Farmacología, Facultad de Ciencias Bioquímicas y Farmacéuticas, UNR. (2) CONICET. (3) Anatomía y Fisiología Patológica, Facultad de Ciencias Médicas, UNR. (4) CIC-UNR.

The regulatory peptide apelin is the endogenous ligand for the orphan G protein-coupled receptor APJ. The apelinergic system has been demonstrated to be involved in the pathogenesis of many conditions. Apelin treatment decreased the expression of pro-inflamma-

tory cytokines and improved renal function in ischemia-reperfusion injury.

The aim of this work was to evaluate the expression of i) apelin, ii) toll-like receptor (TLR)-2, inductor of pro-inflammatory cytokines, and iii) heat shock protein 70 (HSP70), endogenous ligand for TLR-2, in the post-ischemic kidney.

Adult male Wistar rats underwent unilateral right renal ischemia for 40 minutes. Reperfusion was allowed for 24 hours (IR) before kidney removal. Sham operated controls (C) were also included in the protocol. Clearance studies and histological examination were carried out. Apelin and TLR-2 mRNA expression was analysed by qRT-PCR; and HSP70 protein expression, by Western blot.

After 24 hours of reperfusion, creatinine clearance significantly decreased and histological observation showed multifocal acute tubular necrosis, intratubular necrotic/apoptotic cells detachment and brush border diminution. Apelin mRNA in the cortex of IR kidneys was decreased (-70%, $p<0.05$) and TLR-2 mRNA was increased (+620%, $p<0.05$) compared with C. HSP70 protein levels in IR were significantly higher than in C samples (arbitary units HSP70/Coomasie blue: C= 4.5 ± 0.5; IR= 14.7 ± 1.7; $p< 0.05$).

In this model of ischemic acute kidney injury, cortical expression of mRNA encoding for apelin, the peptide whose exogenous administration was reported to exert nephroprotective actions in such conditions, is significantly reduced. Associated with the diminution in apelin expression, an increased expression of TLR-2 and its ligand, HSP70, was found. Further investigation is needed to test our hypothesis that apelin protective effects in IR are mediated by modulation of the HSP70/TLR-2/NFκB/inflammatory cytokines pathway.

Key words: acute kidney injury; ischemia/reperfusion; apelin; TLR-2; HSP70

(546) **EXPRESSION OF PROTEINS RELATED TO SODIUM BALANCE IN RENAL MEDULLA AND PERIPHERAL BLOOD LYMPHOCYTES IN A RAT MODEL OF SALT-SENSITIVE HYPERTENSION**

Abstract: The absence of female sex hormones in ovariectomized (oVx) rats alters renal medulla expression of Na^+, K^+- ATPase (NKA), Na^+ K^+ $2Cl^-$ cotransporter (NKCC2) and D1 dopamine receptor (D1DR). During high salt intake sodium excretion is deficient and rats develop salt sensitive hypertension (SSH). The immune system plays a role in arterial hypertension. In lymphocytes, NKA and NKCC2 are associated with cell growth / proliferation. Therefore, the aim of the present work was to study the expression of NKA, NKCC2 and D1DR proteins in the absence of female sex hormones in peripheral blood mononuclear cells (90% of lymphocytes, PBL) from intact female (IF) and ovariectomized (oVx) Wistar rats. The oVx was performed at 60 days of life and rats were studied 90 days post-oVx. During the last 5 days rats received normal (NS, NaCl 0.24%) or high salt intake (HS, NaCl 1%). At day 150, mean arterial pressure (MAP) was recorded and peripheral blood mononuclear cells were isolated by Ficoll gradient. The expression of D1DR, NKCC2, total NKA and NKA dephosphorylation state (NKA is more active when dephosphorylated at Ser 23) was analyzed by Western blot.

Total NKA decreased in IF with HS intake ($p <0.005$ vs IFNS). In oVx rats NS decreased ($p <0.05$ vs IFNS) while HS increased NKA ($p <0.001$ vs oVxNS). dNKA was higher in oVxHS than in IFHS ($p <0.05$). D1DR decreased in oVxNS rats relative to IFNS and increased in oVxHS ($p<0.05$ vs oVxNS). NKCC2 diminished in IFHS ($p <0.05$ vs IFNS), but NKCC2 increased in oVxHS relative to oVxNS and to IFHS ($p <0.05$). oVx rats with HS intake excreted less sodium than IFHS rats and increased MAP (138 ± 4.5 oVxHS vs 110 ± 5.2 mmHg, $p <0.05$ vs IFHS).

As in renal medulla, expression of NKA, NKCC2 and D1DR is altered in PBL cells from oVx rats compared to IF rats. These findings could be potential tools to allow the screening of SSH and to determine the role of the immune system in this pathology.

Keywords: lymphocytes, salt sensitive hypertension, Na^+, K^+- ATPase, ovariectomy

(708) **RENAL CDC42 AND CIP4 EXPRESSION IN AN ISCHEMIA-REPERFUSION INJURY MODEL**

María Fernanda Fussi (1), Facundo Tonucci (2), Juan Vignola (1), Susana Beatriz Marquez (3), Javier Enrique Girardini Brovelli (1, 4), Liliana Alicia Monasterolo (1, 5, 6), Laura Trumper (1, 5), María Cecilia Larocca (1, 3), Sara María Molinas (1, 6)

(1) Área Farmacología. Facultad De Ciencias Bioquímicas Y Farmacéuticas. Universidad Nacional De Rosario. (2) Instituto De Fisiología Experimental – CONICET. (3) Cátedra De Anatomía Y Fisiología Patológicas. Facultad De Ciencias Médicas. Universidad Nacional De Rosario. (4) Instituto De Biología Molecular Y Celular De Rosario – CONICET. (5) CIC-UNR. (6) CONICET.

Acute kidney injury (AKI) is still a significant medical problem. Renal ischemia-reperfusion (IR) injury is one of the main causes of AKI. Cdc42 is a master signaling molecule, involved in the maintenance of epithelial integrity in renal tubules. Cdc42 signals the initial events of the epithelial mesenchymal transition (EMT), which is essential in the response of the injured kidney. Our aim was to contribute to the molecular characterization of the signaling pathways involved in the development of AKI by characterizing specific features of the cdc42 pathway in the IR model. Male Wistar rats (n=6 per group) were subjected to 40 min of unilateral renal ischemia followed by 1 (IR1) or 7 (IR7) days of reperfusion. Controls underwent sham operation. AKI was corroborated by histological and functional studies. Glomerular filtration rate was reduced in IR1 (-54%, $p<0.05$), and recovered in IR7 rats. Cdc42 protein levels, evaluated in renal cortex, were significantly increased in IR1 (+200%, $p<0.05$), and return to control levels in IR7. CIP4 is an effector of cdc42, which also participates in EMT. CIP4 protein levels also increase in IR1 (+1000%, $p<0.05$) and return to control levels in IR7. Cdc42 function is partially regulated by posttranslational modifications that condition its association to cellular membranes. In fact, cdc42 association to membranes is decreased in the IR model. Our previous results suggest that the isoprenyl-cistein carboximetil transferase (ICMT) could modulate cdc42 function in kidney derived epithelial cells. Our present results showed that ICMT mRNA levels, evaluated by RT-PCR, were reduced in IR1 kidneys. In conclusion, we demonstrated that in the IR model, the early stage of renal damage is associated with an abrupt increase of cdc42-CIP4 expression and a decrease in the expression of an enzyme that could regulate cdc42 association to membranes. The significance of this regulatory response in the evolution of AKI remains to be elucidated.

Keywords: renal ischemia-reperfusion; RhoGTPase; Cdc42; CIP4, ICMT

(1000) **RENAL EXPRESSION OF THE ORGANIC ANION TRANSPORTING POLYPEPTIDE 1 (Oatp1) IN RATS WITH OBSTRUCTIVE NEPHROPATHY.**

Romina V. Campagno, Evangelina C. Nosetto, Anabel Brandoni, Adriana Mónica Torres

Área Farmacología. Facultad de Ciencias Bioquímicas y Farmacéuticas. Universidad Nacional de Rosario. CONICET.

The Organic anion transporting polypeptide 1 (Oatp1/Slco1a1) is a transporter localized in the apical membrane of the proximal tubule cells, and in others tissues like liver and brain. Oatp1 mediates the transport of bile acids, steroids, thyroid hormones, β-lactam antibiotics, cardiac glycosides, statins, among others. The purpose of this study was to evaluate the renal expression and the urinary excretion of Oatp1 in male Wistar rats with obstructive nephropathy. Bilateral ureteral occlusion (B) was induced by ligation of both ureters for 24 h (B24, n=6). The studies were performed after 24 h of ureteral releasing. In parallel a Sham group (Sh, n=11) was processed. The creatinine clearance (Cl_{Cr}) was determined by conventional clearance techniques. Renal expression in homogenates (H), membranes (M), and urinary abundance of Oatp1 were evaluated by electrophoresis and Western blotting. Results: Mean ± SEM. Statistic: t-Student (* $p<0.05$). Cl_{Cr} (mL/min/100g b.w.): Sh= 0.47 ± 0.03, B24= 0.07 ± 0.02*; $Oatp1_H$ (%): Sh= 100 ± 3, B24= 81 ± 7*; $Oatp1_M$ (%): Sh= 100 ± 4, B24= 125 ± 3*. Animals from B24 group showed a significant decrease in ClCr confirming the establishment of the pathology. In homogenates, Oatp1 expression was decreased significantly. This could be explained by an increase in degradation or a decrease in

the novo synthesis of the protein. In membranes, the Oatp1 expression was increased, perhaps as a result of an increase in the protein trafficking from the cytoplasm to the apical membrane. Urine samples from B24 group showed a defined band of 83 KDa, which coincides with the molecular weight described for Oatp1, whereas this band was not detected in the urine of Sham animals. To our knowledge, this is the first study that reports the detection of Oatp1 in urine. In obstructive nephropathy, the alterations observed in the renal expression of Oatp1 could affect the renal handling of metabolites and/or therapeutic drugs that are substrates of this protein.

Keywords: Oatp1, kidney, obstructive nephropathy.

(1924) **RENAL PROTEIN HANDLING IN FABRY DISEASE NEPHROPATHY**

Cristian Costales (1), Abril Seyahian (1,2), Federico Ochoa (1,2), Nestor Lago (3), Elsa Zotta (1,2)
(1) Departamento de Ciencias Fisiológicas IFIBIO Houssay Conicet Facultad de Medicina. (2) Cátedra de Fisiopatología Facultad de Farmacia y Bioquímica. (3) Centro de Patología Experimental y Aplicada Departamento de Patología Facultad de Medicina.

X-linked recessive disease due to alpha-galactosidase deficiency A that determines the accumulation of glucosphingolipids as intracellular globotriaosilceramide (Gb3). The prevalence of the disease is 1/40000 live births. This enzyme appears in the lysosomes of the whole organism, so the disease goes through systemic manifestations. Nephropathy is associated with the accumulation of lysosomal inclusions at the level of podocytes. The first renal manifestations are deficiencies in the capacity of urine concentration, but in adulthood renal insufficiency and proteinuria caused by the alteration in the filtration barrier appear. Megalin is an endocytic receptor type LDLR, identified at the podocyte level and apical membrane of the proximal tubule, with multiple protein ligands such as albumin. The aim of the study is to study tubular causes of proteinuria as an additional mechanism to the urinary excretion of proteins in Fabry's disease. Immunohistochemistry techniques were performed on 11 samples. Biopsies in paraffin (3) and electron microscopy (8), previously dewaxed or exposed to saturated sodium hydroxide solution respectively, for further processing for fluorescence and peroxidase-DAB immunostaining. Megalin (1/50; Abcam, USA) was used as the primary antibody. Signal was detected for megalin in the cytoplasm of the proximal tubules. Taking into account that the normal expression pattern is at the apical border, our results suggest an alteration in protein endocytosis due to lack of recycling of megalin that would indicate a mixed origin of proteinuria.

Key words: Fabry, Proteinuria, Megalin, Podocyte,Gb3.

(982) **ADVERSE EFFECTS OF OPTIONAL HPV VACCINATION ON TEENAGERS IN CÓRDOBA, ARGENTINA (2011-2015)**

Claudia Elizabeth Guerrero
Instituto Universitario de Ciencias Biomédicas de Córdoba - IUCBC

INTRODUCTION

HPV is a sexually transmitted virus which causes vagina and anal cancer as well as an important health problem in this population.

There are two vaccines (Gardasil and Cervarix) in Argentina since the year 2011.

The adverse reactions in clinical trials were local (82.9%) and fever (13%). Arthritis, arthralgia and arthropathy were informed (1.1%). Only 6% of were severe.

1- To collect information about the teenagers' level of knowledge of HPV, ways of infection and prevention.

2- To determine the percentage of vaccinated teenagers.

3- To demonstrate the ARMs related to this population.

4- To compare the adverse reactions of the surveyed group to the ones registered by the National Administration of Drugs, Food and Medical Devices (ANMAT) **MATERIALS AND METHOD:**

A survey was conducted in high school students of both sex pertaining to a group age between 15-18 years old in public and private schools in the city of Córdoba.

The adverse reactions reported by the ANMAT were investigated in order to compare them to the results showed by the survey.

RESULTS:

100 teenagers of private and public high schools of the province of Córdoba were surveyed: 50% of them were girls and the average age was 16 years old. 72% of them acknowledged HPV as a sexually transmitted virus with common lesions: verrucae (47%). 70% of the surveyed find the masculine condom as the prevention item.

Regarding vaccines, 74% of them know about their existence but, paradoxically, 75% of them are not vaccinated. Vaccination for those who did it was due to medical prescription and they do not report adverse reactions. Although these data, 65% assert they would get vaccinated.

FINDINGS:

No significant adverse reactions were showed in those vaccinated teenagers; thus the findings are in line with those registered by the ANMAT since the beginning of the vaccination

(624) **ALTERATIONS OF THE QTC INTERVAL IN PATIENTS UNDER TREATMENT WITH BETA-LACTAM ANTIBIOTICS**

Guillermo Alberto Keller, María Cecilia Villa Etchegoyen, Sebastián Mrad, Roberto Alejandro Diez, Guillermo Di Girolamo
Centro de Vigilancia y Seguridad de Medicamentos, Facultad de Medicina, Universidad de Buenos Aires.

Abstract: drug-induced QTc-interval prolongation is a frequent reaction. There are no studies evaluating its frequency with beta-lactam antibiotics used for low respiratory infections. Objective: to evaluate beta-lactam effects on QT-interval prolongation in the clinical setting, frequency and risk factors. Research design and methods: medical history and comorbilities were registered for patients requiring low respiratory infections treatment. Patients receiving clarithromycin (known QTc-prolonging drug) were used as a positive control. Patients receiving ceftriaxone (no reported cases of QTc prolongation) were used as a negative control. Ionograms and ECGs were performed: baseline and intratreatment; QT was corrected with Bazzet, Fridericia, Framinghan and Hogdes formula. Results:100 patients were included (55 men) with a mean age ± SD (range) 60 ± 13 (40-84) years, weight 78.1±12.1 (51.0-96.0) kg, and body mass index 27.37±2.38 (21.23-32.15) kg/m2. No electrolytes disturbances were detected. Prior to initiation of pharmacological treatment, the patients had: QTcB 453±19 (367-480), QTcFri 425±24 (373-466), QTcFra 422±25 (357-465), and QTcH 427±16 (396-460) ms. Patients were treated with standard doses of Ceftriaxone (N=41), Clarithromycin (N=37), Ampicillin + Sulbactam (N=39), and Piperacillin + Tazobactam (N=20). Clarithromycin was coadministered with ceftriaxone (20) or ampicillin + sulbactam (17). During treatment ECG shows QTcB 431±25 (377-485), QTcFri 415±24 (357-463), QTcFra 415±23 (363-463), and QTcH 413±22 (361-462). QTc Interval prolongation was detected for clarithromycin ($p < 0.001$) and ampicillin + sulbactam ($p < 0.01$). The independent factors that correlated with QTc prolongation were: heart rate, arterial saturation, use of clarithromycin, ampicillin + sulbactam and piperacillin + tazobactam. Conclussion: beta-lactam antibiotics are associated with a small risk for QTc prolongation that may be additive to other clinical factors that must be monitored.

Keywords: antibiotics, QT-interval prolongation, pharmacovigilance, torsades de pointes

(716) **APPLICATION OF PROPOFOL BY IMMERSION AS ALTERNATIVE FOR THE MANAGEMENT OF CARP (*Cyprinus carpio*)**

Natalia Urzúa Pizarro (1), Guillermo Fermín Prieto (1), Carlos Alberto Errecalde (1), Victor Salina (2), Miguel Mancini (2), Maria Paula Tonini (1), Jimena Messina (1)
(1) Farmacología, FAV, UNRC. (2) Acuicultura, FAV, UNRC.

In aquaculture the use of anesthetics is frequent, due to the exposure of fish to stress that affect survival and productive performance, such as manipulation, artificial reproduction and transport. The objective of the present study was to evaluate the depressant activity

of propofol in carp (*Cyprinus carpio*), an anesthetic agonist of the inhibitory activity of GABA. Although there is a history of safety and its pharmacokinetics in cultured fish, its use as an anesthetic has not been reported in aquaculture. Twenty fishes with a total length and average weight of 45.5 ±2.6 cm and 1.5 ±0.3 kg, respectively were used. Three plastic containers of 50 liters each were used with water from the lake to maintain environmental conditions and minimize stress. The methodology of the work consisted of: 1) acclimatization of fish in a container without drug to register basal respiratory rate after adopting normal swimming behavior; 2) transfer to the second container with propofol at 5 ppm, recording times of lateral balance loss and anesthesia and respiratory rate; 3) transfer to the third container without drug registering its behavior and recovery. Statistical treatment of data was carried out with non-parametric Mann-Whitney test. As a result we found that propofol significantly reduced ($P< 0.05$) the respiratory rate from 72.0 ±8.2 to 55.6 ±13.3 opercular movements per minute. The time of loss of lateral balance and anesthesia were 49.0 ±12.1 and 87.3 ±33.0 seconds and the total recovery was 244 ± 95.3 seconds. No signs of excitation were recorded as well as dead specimens up to 96 hours after the administration of the drug. The results obtained indicate that propofol is a safe and effective anesthetic for *C. carpio* management.

Key words: propofol, *Cyprinus carpio,* sedation

(1697) **EXTRACELLULAR VESICLES SECRETED BY THE RAT SUBMANDIBULAR GLAND: ORIGIN, SIZES AND TRANSPORTED NUCLEOTIDASES**

Betina Orman, Matias Barbieri Van Haaster, Emmanuel Quinteros Villarruel, Teresita Ferrary, María Belén Benitez, Graciela Stranieri, Debora Gonzalez
Facultad de Odontología. UBA

The rat submandibular gland (SMG) incubated *in vitro* releases nanovesicles with nucleotidase activity. The objective of this work was to verify the acinar origin of the vesicles and to identify enzymes responsible for catalyzing the hydrolysis of extracellular nucleotides. Methods: SMG fragments of 80-day male Wistar rats were washed and then incubated for 30 'at 37 ° C in physiological solution (pH 7.4). The incubation media were successively centrifuged 15 'at 2000 g and 60' at 27000 g to pellet the vesicles. Tissue sections and vesicles were analyzed by transmission electron microscopy. The vesicular diameter was measured with Image-J software. Nucleotidase activities were evaluated by measuring with a colorimetric technique the phosphate released by incubating the vesicles with 3 mM MgATP, MgADP or MgAMP. Nucleotidases were located in the vesicles using specific antibodies and immuno-labeled with colloidal gold. Results: Size distribution indicated that released vesicles could be a mixture of exosomes (50-100 nm) and plasma membrane derived vesicles (>100 nm); the lumen next to the apical side of acinar cells contained vesicles which size and morphology are compatible with isolated ones. ATP hydrolysis rate decayed 85% along incubation time ($vi= 4.10^{-4}$ μmol $Pi.min^{-1}.mg\ SMG^{-1}$, $T1/2= 1$ min), which can be attributed to NTPDase2, an ecto-ATPase that is inactivated as it hydrolyzes ATP. Incubation of vesicles in the presence of ADP or AMP gave markedly lower activities, stable over time, that could be associated to NTPDases 1 or 3 (for ADP hydrolysis) and ecto-5'nucleotidase (for AMP hydrolysis). Immunogold labelling of NTPDase1, -2 and -3, and 5'nucleotidase indicate that some vesicles carry these molecules, especially NTPDase2 and 5'nucleotidase. Conclusions: rat SMG secrete extracellular vesicles containing nucleotidases that could regulate extracellular ATP, ADP and adenosine concentrations and purinergic responses in gland ducts or oral tissues via saliva.

(1927) **RESVERATROL EFFECTS ON GLUCOSE, INSULIN AND LIPIDS: A SYSTEMATIC REVIEW AND META-ANALYSIS ON RANDOMIZED CONTROLLED TRIALS**

Maria Graciela Lopez Ordieres

It has suggested that resveratrol has anti-aging, anti-carcinogenic, anti-inflammatory, and anti-oxidant properties that might be relevant to chronic diseases like diabetes, obesity, metabolic syndrome. But the evidence is contradictory. The aim of this review was to evaluate the efficacy of resveratrol treatment on fast glucose control, insulin sensitivity and lipids levels in randomized controlled trials (RCTs).

The strategic search included PubMed and other databases, from January 2010 to December 2016, to identify RCTs investigating the impact of resveratrol to control fast glucose, insulin sensitivity and lipid metabolism (cholesterol, TG, HDL and LDL). Key words were resveratrol, clinical trials and humans. The size effects were calculated based on the standardized mean difference (d), heterogeneity was calculating by Q and I^2.

According inclusion and exclusion criteria 15 RCTs were selected, a total 465 of subjects were included in this meta-analysis. The size effect of fast glucose was not significant as indicated d= -0.15 (95% CI: -5.9 and -3.2, p= 0.38, n=15). Also for insulin sensitivity d=-0,02 (95% CI:-2.73 and 2.60, p=0.95,n=9); for cholesterol d=-0.15 (95% CI: -0.38 and 0.23, p=0.56, n=10); for triglycerides d= 0.04 (95% IC: -0.27 and 0.31, p= 0.88, n= 11); for HDL d=-0.19 (IC%95: -0.09 and 0.05, p= 0.63, n=10) and LDL d=0.19 (95% IC: 0.19 and 0.37, p=0.46, n=9). Forest plots were constructed with these data.

Heterogeneity was significant only for glucose with an index of 88% due to two studies with opposite results without bias of publication. The overall outcomes of the meta-analysis indicate that resveratrol daily consumption, doses 8- 3000 mg, during periods 2-3 weeks cannot significantly modify fast glucose control, insulin, cholesterol, TG, LDL and HDL. This systematic review demonstrated that there no scientific evidence to recommend resveratrol for chronic pathologies like diabetes, obesity and metabolic syndrome.

Keywords: resveratrol, systematic rewiew, diabetes, obesity, metabolic syndrome

(312) **METHOTREXATE ADD-ON EFFECT TO ANTIPSYCHOTICS: A CASE REPORT**

Guillermo Hönig (1), Silvia Wikinski (2)
(1) Servicio 25 B, Hospital Neuropsiquiátrico J.T. Borda, Gobierno de la Ciudad Autónoma de Buenos Aires, Argentina. (2) CONICET- Instituto de Farmacología, Facultad de Medicina, Universidad de Buenos Aires, Argentina.

Objective: Our goal is to present the case report of a patient with comorbid diagnoses of schizophrenia and psoriasis where the positive response to antipsychotics is related to the administration of immunosuppressive treatment.

Methods: A hospitalized 43 year old male with diagnosis of schizophrenia according DSM-IV criteria was followed over 15 months. His psychiatric disease lasted for over 20 years at the time of admission when also comorbid psoriasis was detected. Response to the antipsychotic treatment was evaluated by the Positive and Negative Syndrome Scale (PANSS). Treatment of psoriasis was conducted by dermatologists.

Results: After nine weeks of treatment with risperidone (4- 6 mg/day) PANSS score was 119. Clozapine (350 to 900 mg/day) associated with methylprednisone (20-40 mg/day) for the treatment of psoriasis improved both comorbid conditions (PANSS = 77), but suppression of methylprednisone was followed by a PANSS score of 105 points. After 13 weeks, clozapine was replaced by olanzapine (10-50 mg/day) and a conventional scheme of methotrexate + folic acid (10 mg/ 1 g respectively) was indicated for 2 weeks. While psoriasis improved, no changes in PANSS score (= 119) were observed. After 12 weeks, olanzapine was replaced by haloperidol (10-30 mg/day). After 10 weeks with haloperidol, a flare of psoriasis led to the reinstatement of methotrexate + folic acid for 4 weeks, and 10 weeks later (week 24^{th}), methotrexate was indicated on a chronic basis. This scheme induced a significant and persistent improvement in the psychiatric condition (PANSS = 61 points). The patient was discharged from hospital. After discharge, a scheme of risperidone (4 mg/day) and methotrexate as indicated above was accompanied by PANSS score of 51.

Conclusion: Further evidence about potential benefits of adjunctive immunosuppressant treatment to antipsychotics in resistant schizophrenia could be of interest .

(1583) **PERSISTENCE OF *Human papillomavirus* AFTER TREATMENT IN CASES OF INVASIVE CERVICAL CANCER IN NORTH OF BRAZIL**

Alejandra Maria Maradiaga Ortega, Yana Cardoso De Lima, Breno Leonardo Da Silva, Hellen Thaís Fuzii, Fabiola Elizabeth Villanova, Maria Rosana Ramirez

Immunophatology Laboratory- Tropical Medicine Nucleus-Federal University of Para-Brazil

Abstract: In the Pará State, North of Brazil, cervical cancer is the most frequent gynecological malignancy in women; the incidence of this cancer was estimated in 820 new cases of cancer, according to the National Cancer Institute (INCA, 2016). The *Human Papillomavirus* (HPV) is a sexually transmitted infection and this virus is considered the causative agent of the cervical carcinoma; it has more than 200 different viral types, of these, some are oncogenic or high risk types. **Objectives**: To investigate the persistence of HPV-DNA in cervical samples before and after cancer treatment with radiotherapy and / or chemotherapy. **Materials and methods:** Twenty nine women attended at Ophir Loyola Hospital-Belém- PA with invasive cervical cancer were enrolled in the study. Two samples for each patient were collected (smear of the endo an ectocervix) before and after the oncological treatment (fifty-eight samples in total). The cervical samples were tested for the presence of HPV DNA using nested- polymerase chain reaction (PCR) with My9/11 and GP5/6 primers. **Results:** The presence of HPV was detected in 82% (24/29) of the samples of women before treatment and in 68% (20/29) in the samples of women that completed treatment. It was found that in 75% (18/24) of women the HPV virus persisted after treatment, 25% (6/24) cleared the infection (p=0,3). **Conclusion:** In our study the prevalence of HPV DNA detected by PCR for the entire group of women with invasive cervical cancer was 75% HPV-DNA persistence after radiotherapy and/or chemotherapy could be a predictor for disease recurrence or disease outcome.

Key words: HPV, cervical cancer, PCR, viral persistence

(493) **RISK MANAGEMENT PLAN (RMP): APPLICATION IN ARGENTINA**

Francisco Bagnato, Juan Carlos Fernández, Héctor Alejandro Serra

Cátedra de Farmacología, Medicina, UBA

A RMP is formulated to improve the drug safety profile, minimizing risks, favoring phase IV post marketing pharmacovigilance (PVG) and minimizing risks during the drug's life cycle. The aim of this work is to analyze a temporal sample of RMPs and their corresponding Active Pharmaceutical Ingredients (API) in Argentina during 2012-2015. We reviewed data from all APIs and drug associations accompanied by their RMPs submitted to the Administración Nacional de Medicamentos y Tecnología Médica (ANMAT). Data analysis was performed using an MS Excel 2007 worksheet. From 181 APIs and 39 associations, 460 RMPs were submitted (18% biological products; 2% vaccines; 24% oncological products except biological ; 4% antivirals alone except biological; 40% other products; 12% associations). The RMP/product ratios were 2.24 and 1.38 for APIs or associations respectively, indicating the interest of pharmaceutical industry for new APIs. Of 460 RMPs; 41 (8.9%) were updated by default and 5 (1.1%) were from products withdrawn from market. Analyzing their respective risk, 6 API and 3 associations did not need their corresponding RMPs.

Drug safety is a higher interest issue because of social impacts and the burden for health system. Clinical trials may be safe-limited due to the number of patients exposed, and unfortunately, many countries included Argentina have sub-registries on spontaneous PVG. Thus, RMPs are vital to define earlier phase IV safety. Drug manufacturers or marketers, particularly if they will introduce an innovator, should present a RMP in order to evaluate its safety impact and periodically update it according to population exposed. In the case of high-cost treatments, rare diseases or special conditions treatments, the RMP updating is of major importance.

Keywords: risk management plan, pharmacovigilance, drug safety

(1197) **TEACHING ON THE MEDICINES RATIONAL USE IN AN EDUCATIVE CENTER OF ELEMENTARY AND SECONDARY LEVEL OF ARGENTINA**

Alicia del Carmen Panini (1), Marisa Hilda Garraza (1), Mauricio Roberto Teves (1), Graciela Haydée Wendel (1), María de los Ángeles Belotti (2), Emiliano Giraudo (1), Jésica Daniela Paredes (1), Susana Cristina Salvetti (1), Lucía Diez (1), Michael Altgelt (1), Flavia Rocío Robles (1), Franco Matías Albornoz (1), Leonela Marysol Lucero Fernández (1), Ramiro Ezequiel Hariyo (1), Claudia Patricia Calderón (1)

Education is an essential component of our lives, so better training will enable us to make optimal decisions. In referring practice to medicines use, the community formation involves efforts that must overcome the competence of an abundant persuasive promotion that only aims to increase consumption and, attached to a disinformation of society, reflects us complexity of the context and the tasks to be carried out. The objective of university extension project was develop educational activities aimed at school students of 6-18 years of educative center of San Luis province, due the role they play as consumers and by the multiplier effect of their training. Information on aspects related to medicines, such as their appropriate use, encouraging medical or pharmaceutical consultation and discouraging the self-medication, therapeutic non-compliance and the purchase of medicines outside authorized establishments was provided. Training lectures, distribution of educational brochures, games and surveys were prepared; furthermore, a final contest in which students developed a publicity auditory spot on medicines rational use was proposed, which were posteriorly emitted in school radio. Students were separated by educational level for the activities. A great adhesion and participation was observed, based on questions and comments made by students, evidencing a great change in the perception on the use of medicines. Education is an important implement in promoting of medicines rational use, a knowledge that must be increased, particularly in school sector due to that during their adolescence, the young's begin to become aware of the meaning of their social role as consumers. Also, it is important take into account that most consumption habits acquired in this stage will keep forever and that additionally, most of they do not have the necessary training to carry out responsible consumption.

(403) **EFFECT OF THE CALCIUM CHANNEL BLOCKERS AMLODIPINE AND DILTIAZEM ON ERYTHROPOIETIN-MEDIATED ANGIOGENESIS**

Romina Eugenia Maltaneri, Agustina Schiappacasse, María Eugenia Chamorro, Alcira Beatriz Nesse, Daniela Cecilia Vittori

Universidad de Buenos Aires. Consejo Nacional de Investigaciones Científicas y Técnicas. Instituto del Departamento de Química Biológica (IQUIBICEN) de la Facultad de Ciencias Exactas y Naturales. Buenos Aires, Argentina.

Calcium (Ca) is an important factor involved in cell migration. Our group has previously demonstrated its participation in the promigratory effect of erythropoietin (Epo) on endothelial cells. Stemming from this, we hypothesized that Ca channel blockers (CCBs) could negatively affect angiogenesis. This is an important issue since many of these compounds are clinically used as antihypertensives.

Amlodipine (Aml), a dihydropyridine, and the benzothiazepine diltiazem (Dil) are both able to block voltage-dependent Ca channels (VDCCs) in smooth muscle cells. With an aim to determine the ability of these compounds to block Ca channels in the endothelium, we used the EA.hy926 cell line as an experimental model. In accordance to previous reports, we found that both, Aml and Dil prevented staurosporin-induced apoptosis in this cell line (Western blotting, detection of caspase-cleaved PARP-1). However, only Aml decreased

the intracellular accumulation of ROS induced by TNF-α (flow cytometry with the ROS probe DCFH-DA). In inhibition assays, cells were preincubated with Aml or Dil before exposing them to Epo. Epo (200 ng/mL) provoked a significant transient rise in intracellular Ca (<30 s, flow cytometry with Fluo-4AM), which was abrogated by both channel blockers. Wound healing assays (15 h) revealed an inhibitory effect of Aml (1 μM) on Epo-induced cell migration (Control: 25.6±1.6% *Epo: 34.8±2.0%, #Epo+Aml: 22.4±2.7%; *P<0.05 vs. Control, #P<0.01 vs Epo, Kruskal Wallis-Dunn, n=7) while Dil (5 μM) showed no activity (Control: 25.0±1.6%, *Epo: 32.4±1.5%, Epo+Dil: 33.4±2.6%; *P<0.05 vs. Control, Kruskal Wallis-Dunn, n=7). Accordingly, Aml, but not Dil, was able to inhibit Epo-induced tube formation in EA.hy926 cells.

These results not only support the much-debated presence of VDCCs in endothelial cells, but also suggest a differential effect of amlodipine and diltiazem on angiogenesis, with possible implications in their coadministration with a proangiogenic therapy.

Keywords: Amlodipine – Diltiazem – Calcium – Angiogenesis – Erythropoietin

INFECTOLOGY 1

(071) IMMUNE-ENDOCRINE MODULATION OF OSTEOCYTES RESPONSES DURING *B. abortus* INFECTION.

Ayelen Ivana Pesce Viglietti, María Virginia Gentilini, Paula Constanza Arriola Benitez, Andrea Elena Iglesias Molli, Guillermo Hernan Giambartolomei, María Victoria Delpino
INIGEM

Patients with brucellosis have an imbalance in cortisol/ DHEA ratio in plasma. Bone remodeling process is regulated by hormones. Then, we aimed to study the effect of cortisol and DHEA on osteocytes (the most abundant cells of bone) during *B. abortus* (*Ba*) infection. Cortisol treatment inhibited the expression of TNF-α, IL-6 and RANKL (the main regulator of osteoclastogenesis) induced by *Ba* infection (p<0.001, ELISA). DHEA reversed the effect of cortisol on TNF-α expression, but not on the expression of IL-6 and RANKL during *Ba* infection. *Ba* infection induced MMP-2 by osteocytes (zymography). When cortisol was added during *Ba* infection the secretion of MMP-2 was inhibited. When the infection experiments were performed in the presence of both cortisol and DHEA, DHEA could reverse the inhibitory effect of cortisol on MMP-2 production.

RANKL and TNF-α are the main cytokines involved in osteoclastogenesis in inflammatory conditions. We performed osteoclastogenesis experiments by added supernatants from osteocytes infected with *Ba* in the presence of cortisol and DHEA to osteoclast precursors (RAW 264.7) in the presence of M-CSF. Our results indicated that cortisol inhibit the osteoclastogenesis induced by supernatants from *Ba* infected osteocytes (p<0.001, TRAP staining).

It is known that cortisol regulates target genes by binding to the glucocorticoid receptor (GR). *Ba* infection inhibited GR-α and GR-β expression (p<0.01, RT-qPCR).

The levels of intracellular cortisol is not only dependent on GR expression but also a result of the activity of the isoenzymes 11β-HSD1 (cortisone to cortisol conversion), 11β-HSD2 (cortisol to cortisone). *Ba* infection increased 11**β**-HSD1 expression (p<0.05) and inhibited 11**β**-HSD2 expression by osteocytes (p<0.001, RT-qPCR).

The present study constitutes the first analysis on the immune-endocrine alterations in osteocytes during *Ba* infection and provides an initial background for studying in more detail the role of DHEA during the infection.

Keywords: *B. abortus,* osteocytes, cortisol, DHEA

(072) ADRENAL STEROIDS MODULATE OSTEOBLAST FUNCTION DURING *Brucella abortus* INFECTION

Maria Virginia Gentilini, Ayelén Ivana Pesce Viglietti, Paula Constanza Arriola Viglietti, Andrea Elena Iglesias Molli, Gloria Edith Cerrone, Guillermo Hernan Giambartolomei, Maria Victoria Delpino
INIGEM

Brucella abortus (Ba) induces an inflammatory response that stimulates the endocrine system resulting in the secretion of cortisol and dehydroepiandrosterone (DHEA). Osteoarticular brucellosis is the most common presentation of the active disease in humans and we have previously demonstrated that *Ba* infection inhibits osteoblast function. We aimed to evaluate the role of cortisol and DHEA on osteoblast (MC3T3-E1) during *Ba* infection. Our results indicated that DHEA treatment reversed the effect of *Ba* infection on osteoblast by increasing the proliferation (BrDU, CSFE), cell viability (MTT) and inhibiting osteoblast apoptosis (Annexin V, TUNEL & Hoechst). In contrast, cortisol increased the effect of *Ba* infection. DHEA, also, reversed the inhibitory effect induced by *Ba* infection on osteoblast matrix deposition (Alizarin & Sirius Red staining) in an estrogen receptor (antagonist fulvestrant) and ERK1/2 (specific inhibitor It is known that cortisol regulates target genes by binding to the glucocorticoid receptor (GR). *Ba* infection inhibited GR-**α** and this effect could not be reversed by cortisol or DHEA treatment. *Ba* did not induce changes in the expression of GR-**β**. Besides, the capacity of cells to respond to cortisol not only is dependent on GR expression but also on its intracellular bioavailability. The levels of intracellular cortisol is a result of the activity of the isoenzymes 11β-HSD1 (cortisone to cortisol conversion), 11β-HSD2 (cortisol to cortisone). Alterations in the expression of these isoenzymes in bone cells are associated with bone loss. Our data showed that *Ba* infection increased 11**β**-HSD1 expression. Cortisol treatment inhibited the 11**β**-HSD1 expression induced by *Ba.* DHEA treatment had no effect. *Ba* infection did not induce changes in expression of 11**β**-HSD2.

We conclude that DHEA intervention improve osteoblast function during *Ba* infection. Thus, DHEA could be considered as a new treatment against osteoarticular brucellosis.

(204) EGPE CELLS ARE A GOOD ANTIGEN SOURCE FOR HYDATIDOSIS DIAGNOSTIC IN SHEEP.

Andrea Florencia Maglioco (1, 2), María Eugenia Peralta (2), Oscar Jensen (3), María Laura Gertiser (3), Melisa Barbery Venturi (1, 2), Osvaldo Fridman (2), Gabriela Canziani (1), Alicia G Fuchs (2)
(1) CONICET. (2) CAECIHS-UAI. (3) Centro de Investigación en Zoonosis, Provincia de Chubut.

Echinococcus granulosus is the causative agent of hydatidosis disease, a zoonosis with worldwide distribution. Nowadays, diagnosis of hydatidosis in livestock happens mainly in necropsies. However, an accurate serological diagnostic test would be desirable to monitor livestock in order to prevent the dissemination of the disease in non-endemic zones. A cellular model of *E. granulosus* was established from bovine protoscoleces in our laboratory and it was named EGPE. In these cells AgB4 was detected by immunohistochemistry and DCO1 (Echeverria et al, 2010) and antigen B2 subunit was detected by PCR. Purpose: to identify whether EGPE cell proteins could be recognized by infected sheep serum. Materials and Methods: EGPE cells were cultured in complete medium M199 for short (7 days) or long term culture (20 days), for protein extraction (CE). The CE were obtained in 8 mM CHAPS buffer for 2 hours and 4 freeze-thaw cycles. Serum from 7 infected sheep and 5 non-infected sheep were obtained from Chubut, Argentina and reactivity to EGPE proteins were analyzed by western blot and ELISA. An 18 μg of CE were used per lane for western blot and 1.5 μg of CE were used per well for ELISA. A 1/125 dilution for serum sample, alkaline phosphatase conjugated rabbit anti-sheep (1:5000) and BCIP/NBT (western blot) or p-nitrophenyl phosphate in diethanolamine buffer (ELISA) were used. Results: After 15% SDS-PAGE electrophoresis and immunoblotting, several bands from CE were recognized exclusively by infected sheep: 56-64 kDa and 75-83 kDa in short term culture and 44-48 kDa, 56-64 kDa and 70-74 kDa in long term culture. After ELISA, differences between control and infected sheep were detected in short (p<0.05, Student´s T-Test) and long term culture (p<0.01, Student´s T-Test). Conclusion: EGPE proteins could be used as a source of standardized antigenic material for diagnostic of hydatidosis in infected sheep.

Keywords: Hydatidosis, Serology, Sheep, EGPE cells

(436) INVOLVEMENT OF A HALOARCHAEAL RHOMBOID PROTEASE IN CELL ADHESION AND MOTILITY

REGULATION

Mariana Ines Costa (1), Micaela Cerletti (1), Christian Troetschel (2), Ansgar Poetsch (2), Rosana Esther De Castro (1), Mechthild Pohlschroder (3), Roberto Alejandro Paggi (1), María Inés Giménez (1)
(1) Instituto de Investigaciones Biológicas, UNMdP-CONICET. (2) Plant Biochemistry, Faculty of Biology & Biotechnology, Ruhr University Bochum, Germany. (3) Biology Department, University of Pennsylvania, USA.

Rhomboids are a family of intramembrane serine proteases represented in the three Domains of Life. These enzymes participate in gene regulation and cellular signalling in eukaryotes, but little is known about their targets in prokaryotes, such as Archaea. Our previous work showed that deletion of one of the two Rhomboid protease genes (*rhoII*) has a global effect on the proteome of the haloarchaeon *Haloferax volcanii* (membrane and cytoplasm fractions). In addition, some putative RhoII targets (direct or indirect) were identified, including pilin pilA1, prepilin/preflagellin peptidase PibD and PrsW protease.

To validate these results in this work we analysed PibD and PrsW processing in *H. volcanii* wild type (H26) and ΔrhoII (MIG1). An *in vivo* assay suggested that the differences in PrsW level (29 fold reduction) previously observed in MIG1 may be due to an indirect effect of the *rhoII* mutation. On the other hand, preliminary Western blotting analysis of *H. volcanii* H26 and MIG1 membrane samples, indicated that PibD may be processed in a RhoII dependent manner. Overexpression of PibD natural substrates (pilins 1-6) in H26 and MIG1 strains showed differences in the amount of these proteins in cell extracts and culture supernatants, suggesting that they may be indirectly affected by RhoII.

With the aim of completing the initial proteomic study we also analysed and compared the secretomes of H26 and MIG1. We identified 27 differentially represented proteins, including some involved in motility and cell adhesion, such as flagellin1 and the hypothetical protein HVO_1533.

Taken together, our results suggest that RhoII regulates cell adhesion and motility, likely by processing PibD and subsequently affecting the functioning or assembly of pili and/or flagella in *H. volcanii.*

(532) **INTRANASAL IMMUNIZATION WITH THE NOVEL BtaF TRIMERIC AUTOTRANSPORTER FROM *Brucella abortus* IN A MURINE MODEL**

Florencia Muñoz González (1), Gabriela Sycz (2), Iván Alonso Paiva (1), Andrea Fernández (1), Julieta Focaraccio (1), Pablo Baldi (1), Ángeles Zorreguieta (2), Mariana Ferrero (1)
(1) Instituto de Estudio de la Inmunidad Humoral (IDEHU-CONICET-UBA). (2) Fundación Instituto Leloir (IIB-BA-CONICET).

Brucella spp. can be transmitted to humans through mucosae. Currently, there are no human vaccines against this infection. We have previously shown that BtaF is an adhesin involved in the attachment of Brucella spp. to biotic and abiotic surfaces, and that it is important for the dissemination and persistence of the pathogen after intra-traqueal murine infection. Based on these results, we evaluated BtaF as a potential component of an acellular vaccine against brucellosis.

Six-week-old Balb/c mice were weekly immunized for 3 weeks with BtaF (10ug) plus 3',5'-c-di-AMP (c-di-AMP,10ug), c-di-AMP alone or saline. One week after last immunization serum, saliva, feces, bronchoalveolar (BAL) and vaginal lavage (VL) fluids, lung homogenates and spleens were obtained. Levels of BtaF-specific antibodies were measured by indirect ELISA in all samples. *In vitro* production of gamma interferon (IFN-γ), interleukin-5 (IL-5) and IL-2 by spleen cells stimulated with BtaF (10 μg), ConA or RPMI was determined.

Immunized mice showed increased serum levels of total antibodies against BtaF ($p<0.0001$), and of specific IgA in saliva, feces, BAL, VL and lungs ($p<0.0001$; $p<0.0001$; $p<0.05$; $p<0.01$;$p<0.05$) compared with controls. IgA titers in serum were 12800. Serum titers of IgG2a were higher than those of IgG1 (409600 vs. 51200). The IgG1/IgG2a ratio was 0.49. In response to BtaF splenocytes from immunized mice increased their secretion of IFN-γ (495.5 pg/ml, $p<0.05$), IL-5 (454 pg/ml, $p<0.01$) and IL-2 (195.9 pg/ml, $p<0.05$). This increment in IFN-γ production was abolished when CD4+ cells were depleted ($p<0.01$) but not with CD8+ cells depletion.

Intranasal vaccination with BtaF plus c-di-AMP induced a systemic and mucosal specific immune response, which may contribute to prevent the mucosal entry of Brucella and its dissemination. The activated cellular immune response shown by high levels of IFN-γ, was dependent on CD4+ cells and may be crucial for this vaccine protective effect.

Key words: Brucellosis, mucosae, intranasal vaccine, adhesin

(857) **RHOX, A RHOMBOID PROTEASE OF *BRUCELLA ABORTUS* INVOLVED IN PATHOGENESIS**

Manuel Facundo Fungueiro (1), Claudia K. Herrmann (1), Leonardo Panunzi (1), M. Inés Marchesini (1), Diego J. Comerci (1)
(1) IIB-INTECH UNSAM CONICET.

The intramembrane serine proteases from the rhomboid family are widespread among the different organisms and have many biological functions. Despite the lack of homology between their sequences, they all seem to cleave their substrates within the lipid bilayer by a conserved mechanism. However, little is known about the role of most of these enzymes during intracellular lifestyle of many pathogens. Our group recently identified substrates of *Brucella abortus* VirB type IV secretion system (SST4) involved in pathogenesis. One of them, RhoX (BPE275), is the only rhomboid protease present in *B. abortus* whose function is still unknown. Deletion of RhoX affects Brucella internalization. Homology sequence analysis by ClustalW revealed that despite differences in their sequences, RhoX have conserved specific regions relevant for protein structure and a catalytic dyad (Ser153-His227) responsible for the enzymatic activity. Furthermore, activity assays using *B. abortus* membrane preparations demonstrate that RhoX is an active rhomboid protease able to cleave substrates of other members in the rhomboid family such as Gurken and Spitz of *D. melanogaster*, LacY of *E. coli* and TatA of P. *stuartii.* In an attempt to identify putative substrates for Rhox among *Brucella abortus* proteome, we developed a bioinformatic screening. To validate this screening experimentally, transmembrane domains (TMD) of the putative candidates were cloned into pMal2E vectors as fusion proteins containing, as well, the sequence to encode the maltose binding protein (MBP) and both Flag and His tags. These constructions were expressed in *E.coli* MG1655, a mutant deficient for rhomboid protease, to perform activity assays. In further studies, we aim to study the function and location of BPE275 and its substrates during *Brucella abortus* pathogenesis.

Key words: Brucella, protease, rhomboid, internalization

(1061) **BIGA AND BIGB FACILITATES *Brucella* ADHESION AND INVASION TRIGGERING CYTOSKELETON REARRANGEMENTS OF HOST CELLS**

Paula V Lopez, Francisco Guaimas, Cecilia Czibener, Juan E Ugalde
IIB INTECH UNSAM CONICET

Brucella are gram-negative intracellular bacteria that cause brucellosis, one of the most world-wide distributed zoonosis. The capacity of these bacteria to cause disease relies in their ability to invade and survive in the host cells. Adhesion to cells is the initial step in the virulence process of many pathogens and, therefore, is a central process to understand the bacterial pathogenic cycle. Our group has identified a unique gene cluster present in all *Brucella* species and important in the infectious process, participating in the adhesion to host cells. This region codes for four open reading frames: Bab1-2009, Bab1-2010, Bab1-2011 and Bab1-2012. Bab1-2009 and Bab1-2012 localize in the outer membrane and have a domain with homology to bacterial immunoglobulin-like domains (Blg-like). We found that both of these genes code for powerful adhesins that mediate attachment/adhesion to non-phagocytic host cells and for this reason we named them BigA and BigB respectively. We have shown that the addition of the recombinant Blg-like domain of BigA to HeLa and MDCK cells induced profound cytoskeletal rearrangements.

With the purpose of further understanding the role BigB could be playing in the interaction with host cells we recombinantly produced the BIg-like domain of BigB and treated HeLa cells. As with BigA, BigB induced profound cytoskeleton rearrangements that ended with the cells detaching from the plate. Additionally we tested if BigB may also cooperate or interact with BigA by treating non-phagocytic cells with both adhesins individually and in combination and assessing cell morphology as well as cytoskeleton integrity. Our results suggest that these adhesins have additive effects but need further work in order to understand at the molecular level how they enhance adhesion and invasion. Keywords: Brucella, adhesion, adhesin, cytoskeleton.

(1333) **CONTROL OF THE O-ANTIGEN CHAIN LENGTH IN *Brucella***

ALEXIS ROMANI (1), MARIELA DEL GIUDICE (1), ADRIANA CASABUONO (2), ALICIA COUTO (2), CECILIA CZIBENER (1), JUAN UGALDE (1)
(1) IIB-INTECH, UNSAM CONICET. (2) UBA, FCEyN, Departamento de Química Orgánica.

Bacteria of the genus *Brucella* are gram-negative coccobacilli that cause brucellosis, a world-wide distributed zoonosis. Lipopolysaccharide (LPS) is the main component of the extracellular side of the outer membrane of the bacteria and constitutes the first physical barrier that protects them from the environment and, therefore, is central for the virulence of many pathogens. The LPS is composed of three parts, the lipid A, the oligosaccharide nucleus and the terminal polysaccharide terminal O-antigen. Although several genes that participate in the synthesis of LPS have been identified, the mechanism that regulates the length of the O-antigen is currently not known. Previous results indicated that *Brucella* actively controls the length of the O-antigen and in the search for putative genes that could play a role in this control we identified *wbkB*, a gene with no known function, present in the O-antigen synthesis cluster that codes for a protein with a putative glycosiltransferase domain. A deletion mutant in *wbkB* exhibited longer O-antigen chains measured by western blot and MALDI-TOF. Topology studies using fusions to b-galactosidase and to the alkaline phosphatase showed that the putative glycosiltransferase domain could be facing the citoplasmic side of the inner membrane strongly suggesting that this protein could be acting on the lipid-intermediate. A double mutant *pgm/wbkB* that accumulates the lipid-intermediate reinfoced this hypothesis. Additionally, infection assays with the *wbkB* mutant in cultured cells showed that the inability to control the O-antigen chain length affects virulence. In subsequent studies we will try to understand mechanistically how WbkB operates to regulate the of the O-antigen and how this fine tuned regulation affects the virulence process.

Keywords: *Brucella*, Lipopolysaccharide, O-antigen, Topology.

(981) **FOODBORNE DISEASES BY *Salmonella enterica* serovar Enteritidis DURING EARLY STAGES OF PUERPERIUM INDUCE AN ADVERSE MATERNAL OUTCOME IN THE MURINE MODEL.**

Mariangeles Noto Llana (1), Lucia Krummel (1), Ailin Garofalo (1), Roberto Meiss (2), Diana Betancourt (1), Sebastian Sarnacki (1), Fernanda Buzzola (1), Cristina Cerquetti (1), Monica Giacomodonato (1)
(1) IMPaM-UBA-CONICET, (2) Patología Experimental. Academia Nacional de Medicina

Diarrheal disease agents, especially non-typhoidal *Salmonella enterica* (S. Enteritidis), are responsible for the majority of deaths due to foodborne diseases (FBD). Puerperium is a predisposing condition for exacerbation of infections. Our aim was to study the effect of FBD by *S.* Enteritidis during the early puerperium. To this purpose, we used an enterocolitis model. BALB/c mice received 20 mg of streptomycin 48 hs postpartum. 24 hs later they received 3,500 CFU of *S.* Enteritidis intragastrically (sub lethal dose). At day 3 post infection (day 6 postpartum) intestinal permeability was measured in vivo. Gut samples were analyzed for bacterial colonization, histological changes and tight junctions mRNA levels. Ileum and serum citoquines expression were studied by qPCR and ELISA, respectively. We found that 86% of puerperal females died within 5 days post infection whereas the mortality rate of infected virgin mice was 20%.This adverse maternal outcome is correlated with massive bacterial organs colonization. Also, gut permeability was significantly increased in infected parturient females ($p<0.05$) respect to control mice (non infected postpartum females, infected and non infected virgin females). Histology of serial cross sections showed irregular mucosa with decreased villus height, MALT hyperplasia and detriment of goblet cells versus no significant histological changes in non infected mice. Moreover, Claudin4 mRNA levels were 3 fold higher in infected parturient mice than control groups ($p<0.05$) while Zona occludens showed no significant differences. IFN-γ and IL-17 expression was up regulated in infected maternal gut and serum vs control mice ($p<0.05$). In summary, this work demonstrates that FBD by *S.* Enteritidis during early stages of puerperium cause negative effects on host survival probably by the increased gut permeability due to maternal immune response. Infected puerperal females are unable to self-limit the infection leading to fatal illness.

Key words: *Salmonella*, puerperium, enterocolitis, inflammation, foodbourne disease.

(1795) **INTESTINAL NECROTIC DAMAGE CAUSED BY *Clostridium chauvoei* IN MICE**

María Julia Divizia (1), Rodrigo Alberto Guerra (1,2), Sofía Quiroga (1), María Cecilia Villa (1,2), Walter Berón (3), Teresa Inés Cortiñas (1)
(1) Universidad Nacional de San Luis. (2) Universidad Nacional de Villa Mercedes. (3) Instituto de Histología y Embriología "Dr. Mario H. Burgos".

The definition of the term "Sudden Death Syndrome" (SDS) often includes feedlot cattle found dead unexpectedly. The specific causes of death frequently can be determined by necropsy. Etiology and preventive measures are poorly defined. The current literature indicates that sudden death is often associated with digestive upsets. Recently SDS has been associated with specific *Clostridium perfringens* strains infections. *Clostridium chauvoei* is a Gram positive spore forming bacteria, causative agent of blackleg, a mortal myonecrotic disease that affects livestock legs muscles. Blackleg is endemic in Argentina and affects many animals around the world. The objective of this work was to characterize the endogenous infection caused by *C. chauvoei* spores administered orally. *C. chauvoei* ATCC 10092 spores were obtained in a modified clostridial medium, cultured five days at 37 ° C and 13 days at room temperature under anaerobic conditions. Groups of two Rockland mice were orally administered with 10^2, 10^4 and 10^8 spores in jelly-skin milk support during two months. The mice that showed sudden clinical manifestations such as incoordination and weakness, were immediately euthanized. The first deaths were recorded at around the 25th day of the trial. The gastrointestinal tract was collected and embedded in paraffin wax, and stained with hematoxylin-eosin. Intraperitoneal fluid was collected to look for *C. chauvoei* cells. Mice treated showed significant ($p\leq0.05$) weight loss compared to control mice. All the spores concentration assayed in this study, induced intestinal damage in mice. Macroscopic and histological analysis showed necrotic areas in large and small intestine. No *C. chauvoei* cells were found in intraperitoneal fluid. Our results suggest that *C. chauvoei* spores germinate and colonize intestine, leading poor nutrient absorption, mucosal necrotic damage, weight loss and death. Further studies will determine whether *C. chauvoei* could be associated with SDS in animals.

Key words: necrosis, clostridium chauvoei, spores.

FARMACO 2 / PHARMACOLOGY 2

(1769) **RADIOSYNTHESIS OF HYBRID NANOPARTICLES FOR BIOMEDICAL APPLICATIONS**

Constanza Y. Flores
IMBICE-UNQ

Surface modification of gold nanoparticles (AuNPs) with different biomolecules has been used for several decades in rapid diagnostics tests. In last decade, AuNPs have been demonstrated can be

used in therapy and imaging. This is due to their intrinsic biocompatibility and unique properties, dependent on their size, shape and coating. However, protein coating methods based on physisorption are not stable enough to prepare functional nanomaterials to be used in complex mixtures or in vivo applications.

The aim of this work is to prepare and characterize AuNPs coated with human and bovine serum albumin (Alb) multilayers by a novel radiation-induced crosslinking process. These nanostructures were called Au/Alb core/shell nanoparticles (Au/Alb NPs). Albumins from human and bovine source were added to AuNPs suspension followed by ethanol addition (30, 40, 50% v/v ethanol) to induce a dynamic protein aggregation around the AuNPs. The ethanol suspensions were irradiated at 10 kGy with a gamma source to induce a protein crosslinking according to recent findings in our working group (ref Achilli). .

The Au/Alb NPs were characterized by UV-visible and infrared spectroscopy, transmission electron microscopy (TEM) and dynamic light scattering (DLS). NPs containing 30%v/v ethanol showed a plasmon peak at about 532 nm, demonstrating the presence of non-aggregated AuNPs. Using higher ethanol concentrations, the absorbance of plasmon peak showed NP aggregation. DLS measurements were show particle population with an average diameter of about 60 nm was found. Moreover, TEM images showed that the NPs had spherical shape and the presence of a low-density halo around the metal core confirmed the presence of the protein shell.

In conclusion, we were prepared and characterized hybrid NPs by a novel radiation-induced cross-linking technique. These hybrid NPs are composed of Au core and Alb shell, which these were capable to maintain the spectroscopic properties of Alb and optical properties of AuNPs.

(304) **AN ALBUMIN-BASED γ IRRADIATED NANOPARTICLE AS A POTENTIAL NANOVEHICLE FOR DRUG DELIVERY SYSTEMS: BIOPHYSICAL CHARACTERISATION, TOXICITY AND IMMUNE RESPONSE**

Macarena Siri (1), Malvina Pizzuto (2), Natalia Paladino (3), Jean-Marie Ruysschaert (2), Mariano Grasselli (4), Silvia Del V. Alonso (1)

(1) Laboratorio de Biomembranas, Grupo de Biología Estructural y Biotecnología (GBEyB), UNQ-IMBICE-CONICET-CICPBA, Quilmes, Buenos Aires, Argentina. (2) Structure et Fonction des Membranes Biologiques (SFMB), Université Libre de Bruxelles, Bruxelles, Belgium. (3) Laboratorio de Cronobiología, UNQ, Quilmes, Buenos Aires, Argentina. (4) Laboratorio de Materiales Biotecnológicos, Grupo de Biología Estructural y Biotecnología (GBEyB), UNQ-IMBICE-CONICET-CICPBA, Quilmes, Buenos Aires, Argentina.

A bovine serum albumin-based nanoparticle (BSA NP) was achieved by γ-irradiation of a protein ethanol solution. The first part of this study centres on the biophysical characterisation of the nanoparticle. Confirmation of the NP as an entity was stated by D.L.S and microscopic techniques (T.E.M, S.E.M. and A.F.M.). Preservation of the main structural features (α – helix content and main binding pocket) was displayed mainly through spectroscopic experiments: UV-vis, FT-IR, Fluorescence, and C.D.

The functionality of the NP as a drug delivery was study against the drug emodin (E). Fluorescence spectroscopy was used to elucidate the main binding parameters like affinity constant. The binding capacity efficiency and kinetic release profile were also studied. The toxicity of this system (BSA NPE) was tested in two different tumour cell lines: MCF-7 and PC-3. Its haemolytic activity was also tested in human blood cells.

Lastly, we studied the immune response the NP might have *in vitro* and *in vivo* in murine models (RAW BLUE cells and C57/BL6, respectively). In the *in vitro* experiments, all samples activated NF-κB and led to TNF-α secretion, nevertheless this immune response was strongly enhanced for larger BSA NPs suggesting a dependence of albumin immunostimulatory properties on particle size. Preliminary *in vivo* experiments suggested slight activation of DC cells and macrophages in the popliteal lymph node after 72 h incubation.

The BSA NP presented encouraging results to be considered as a nanovehicle for drug delivery systems. It does not only present all the albumin's main features as a drug carrier, but it improved the affinity for the hydrophobic drug together with the kinetic drug release profile.

(1106) **DESIGN AND DEVELOPMENT OF siRNA NANOCARRIERS USING MICROFLUIDIC TECHNOLOGY**

Florencia Giannoni (1), Alvaro José Conde (1), Rodrigo Lloyd (1), María Belén Cerda (1), Julia Milena Gallino Fernández (1), Osvaldo Podhajcer (2), Lucía Policastro (1)

(1) CNEA, (2) Fundación Instituto Leloir.

Nonviral gene vectors are promising vehicles to deliver diagnostic and therapeutic agents *in vivo,* due to their low immunogenicity and biocompatibility. Within therapeutic agents, small interfering RNA (*siRNA*) is an efficient tool for gene silencing because this molecule has a very high potential effect at low doses. However, *siRNA* is manly degraded after its uptake by the endocytic/lysosomal pathway. Complexes containing *siRNA* and cationic polymers or fusogenic peptides are usually performed to overcome this barrier and to facilitate the activity of siRNA into the cytosol. Nevertheless, these kinds of polyplexes are generally obtained by manually mixing *siRNA* and polymers or peptides, generating large and heterogenic complexes with low silencing activity. The global aim of this work is to obtain small, homogenous and effective complexes by microfluidic technology for the silencing of genes associated with resistance to chemo and radiotherapies. Initially we obtained complexes using a *siRNA* against luciferase gene, a cationic polymer named polietilenimine (PEI) and the pH- sensitive influenza-derived peptide, INF7. Complexes were performed mixing manually the mentioned components (standard method, SM) and by using a hydrodynamic focused microfluidic system (MM). The complexes obtained by MM were 50-70% smaller than the ones produced by SM with a significantly reduced polydispersity index. The MM complexes were obtained continuously, fast and with a finely controlled synthesis. Likewise, the MM complexes were successful in silencing the luciferase reporter gene expression with a greater efficiency than those obtained by SM. These results allow us to infer that microfluidic technology is a promising method to obtain small and homogeneous complexes with well-defined structures and composition, to silencing efficiently target genes.

Keywords: Nanovehicles, microfluidics, siRNA, INF7

(386) **DESIGN AND IN VITRO CHARACTERIZATION OF A NOVEL MELATONIN DELIVERY SYSTEM**

Julieta Celeste Imperiale (1), Alejandro Sosnik (2), Gabriela Acosta (1)

(1) ININFA. (2) TECHNION INSTITUTE.

Melatonin is a hormone used for treating circadian rhythm disorders such as jet-lag and insomnia. Also, it has shown anti-tumoral properties on various types of cancers and neuroprotective effects in diseases like Alzheimer and glaucoma. Although it belongs to Class 1 according to the Biopharmaceutical Classification System (high permeability, high solubility), melatonin has low bioavailability (≈15%) due to an extensive hepatic first pass. Furthermore, it exhibits a low dissolution rate and stability problems in aqueous solutions. We hypothesize that these biopharmaceutical disadvantages can be approached through the encapsulation of the drug in muco-adhesive polymeric nanoparticles that undergo intestinal absorption or by their localized administration.

In this work, we present the encapsulation of melatonin in Eudragit® RLPO nanoparticles by a nanoprecipitation technique using acetone as solvent. The hydrodynamic diameter, determined by dynamic light scattering (DLS), ranged from 10 to 100 nm with polydispersity index of 0.118 ± 0.005 and zeta-potential of +54.7 ± +1.8 mV due to the polycationic nature of the polymeric carrier. The high value of zeta- potential predicts good physical stability. In fact, nanoparticles maintained their size and superficial charge for at least two months. Transmission electron microscopy evidenced the spherical

morphology of nanoparticles. The encapsulation efficiency was approximately 100%, as determined by UV-Vis spectrophotometry (λ = 278 nm). The muco-adhesiveness *in vitro* was characterized by mucin solution method by DLS where a significant increase in size and a significant reduction in zeta-potential were observed. Overall, these preliminary results suggest that a platform of melatonin-loaded nanoparticles could be capitalized to improve the delivery of this active molecule by a variety of mucosal routes.

Keywords: Melatonin, nanoparticles, improved delivery

(360) **NANOPARTICLES FOR CARIES LESION INFILTRATION AND POTENTIAL *IN SITU* REPAIRMENT**

Maria Jazmin Silvero (1), Natalia Angel Villegas (2), Martin Sainz Aja (3), Diamela Maria Rocca (4), Maria Cecilia Becerra (1), Gustavo Molina (3), Santiago Daniel Palma (4)
(1) IMBIV-CONICET-FCQ-UNC. (2) UNITEFA-FCQ-UNC. (3) Cat.Mat.Dentales-FO-UNC. (4) UNITEFA-CONICET-FCQ-UNC. (5) FCQ-UNC.

Caries disease produces serious dental damage that eventually evolves in a tooth cavity. The aim of this work was to study the application of nanomaterials to infiltrate decayed tissue and promote a biological repairment response. Zinc nanoparticles (ZnO@NP, 50nm) and gold nanoparticles synthesized and stabilized with an antibiotic (amoxicillin@AuNP, 40nm) were selected for their known antimicrobial capacity and biocompatibility. ZnO@NP produced stable suspensions during 72h in: distilled H_2O, PBS (pH=7.4), Thioglycolate broth, DMEM and Icon^R (a resin-based material mainly composed of tri-ethylene glycol dimethacrylate with high infiltration ability). The amoxicillin@AuNP stability, followed spectrophotometrically, was acceptable in DMEM and Thioglycolate broth (12.5%) for 72h, and was excellent in the resin until 72h. Agregation was noted immediately when mixing the two nanomaterials in brain-heart broth and in H_2O_2 (3%), which were alternatives for the culture of anaerobic bacteria and for infiltration, respectively. The interaction between nanomaterials and the demineralized dental surface was analyzed by SEM (Surface Electron Microscope) with coupled EDS (Energy Dispersive X-Ray Spectrometer). The load of nanomaterial was 22 times higher (Wt%: 42.9 ± 1) in dental samples treated with ZnO@NP carried in resin, than in those treated with ZnO@NP at the same concentration in PBS (Wt%: 1.9 ± 1). SEM images with mapping also showed that amoxicillin AuNP (1.5 µg/mL in PBS 50%) were attached on the dental surface, preferably in the demineralized area. Overall, best results were obtained by employing the resin as a carrier. This adhesive system based on methacrylates improved the nanomaterial adherence and recovered the dental structure by filling the porosities of the simulated lesion. Currently, their infiltration power and their effect on caries producing bacterial strains are being investigated.

KEYWORDS: nanoparticles, zinc, gold, caries, resins

(1859) **GOLD NANOPARTICLES SYNTHESIS AND FUNCTIONALIZATION FOR MITOCHONDRIAL DELIVERY**

Marisa Lia Taverna Porro (1), Irene Ibañez (2), Mariel Atia (2), Cecilia Grissi (2), Francisco García (3), Hebe Durán (2,3)

Melanoma is highly aggressive and its incidence increased significantly over the past decades. Despite the development of improved treatments, patients still have poor prognosis due to its resistance and high recurrence rate. Targeting cancer metabolism has emerged as a promising therapeutic strategy. In this context, multi-resistant melanoma cells have increased mitochondrial respiration and high level of reactive oxygen species. Disruption of this oxidative metabolism, in combination with other conventional therapies, could be an effective means for this highly resistant cancer. However, mitochondrial targeting of therapeutic agents is still challenging. A way to overcome this limitation is by using nanoparticles (NPs). NPs accumulate in tumors by enhanced permeability and retention effect and can be modified for selective mitochondrial targeting. In addition, gold NPs (AuNPs) possess unique electronic properties that make them excellent radiosensitizing agents. Against this background, we propose that AuNPs functionalized with the mitochondriotropic residue triphenylphosphonium (TPP), in combination with radiotherapy, can potentially be used for the radiosensitization of radioresistant melanoma cells.

Citrate-AuNPs were prepared by the Turkevich and Frens method and then functionalized with thiolated PEG polymers containing TPP (AuNPs-TPP). AuNPs-TPP were characterized by UV–Vis spectrophotometry, dynamic light scattering and transmission electron microscopy. AuNPs-TPP of 15.7±1.2 nm, highly homogeneous in morphology, with Z potential of 10±0.8 mV and extremely stable were obtained. Stability was demonstrated by no morphology change upon storage time, exposure to high ionic strength and with NPs concentration. AuNPs-TPP up to 250 µg/ml were not cytotoxic in A375 melanoma cells exposed to these NPs for 24 h. All together, these results show that these novel AuNPs functionalized for mitochondrial delivery can potentially be used as radiosensitizers.

(1727) **HYBRIDS GOLD/PROTEIN NANOPARTICLES DECORATED WITH BIORECOGNITION PEPTIDES.**

Estefanía E. Achilli, Constanza Y. Flores, Silvia Del Valle Alonso, Mariano Grasselli
Laboratorio de Materiales Biotecnológicos. Universidad Nacional de Quilmes; IMBICE.

Functionalization of gold nanoparticles (Au-NPs) surface with different biomolecules has been used for several decades in rapid diagnostics tests. In last years, Au-NPs have been demonstrated can be used in therapy, imaging and delivery applications. This nanomaterial platform could combine those to generate theranostic nanoparticles.

In order to localize the theranostic effect onto some specific cells and focus the therapy, NPs targeting is mandatory by using specific peptides, organic molecules or proteins. In addition to that, it is necessary to reduce non-specific interactions with other proteins which strongly reduce the NPs enrichment in the target. It has been recently recognized that the surface of the NPs and their interaction with serum proteins (´*corona effect*´) has a pivotal role in the final destination in the body. Therefore, the coating process became in a strategic issue to develop functional nanomaterials.

In this context, the aim of this work is to prepare and characterize gold/albumin NPs (Au/Alb-NPs) decorated with DOTA-bombesin (DOTA-BB). The Alb coating is useful for reduction of the *corona effect* and Bombesin to target GRP receptor, present in several tumor cells, such as prostate and breast cancer. DOTA chelator will transport radionuclides.

The Au/Alb/BB-NPs were characterized by UV-visible, dynamic light scattering (DLS), atomic force microscopy (AFM). Determination of DOTA-BB onto surface NPs is performed by MALDI TOF/TOF and by ICP-AES.

Specific NPs uptake has been study by Cytometric Flow Analysis comparing NPs prepared by monolayer physisorption and our method decorated with the specific peptide onto PC-3 cell culture.

Decorated hybrids NPs have less unspecific adsorption and better receptor recognition than the monolayer coated NPs.

Keywords: nanoparticle, biorecognition, gold, albumin.

(130) **PAMAM DENDRIMERS AS AN EFFICIENT CARBAMAZEPINE DELIVERY SYSTEM: NANOTOXICOLOGICAL CHARACTERIZATION**

Daniela Igartúa, Carolina Martinez, Silvia Alonso, Jimena Prieto
Laboratorio de Biomembranas, Universidad Nacional de Quilmes. Grupo vinculado GBEyB, IMBICE-CONICET

Carbamazepine (CBZ) is on the market as an antiepileptic. It also has potential uses for the treatment of numerous neurodegenerative diseases. However, it has low solubility in aqueous media, inefficient pharmacokinetic profiles and multiple side effects, so it is important to avoid widespread distribution. Drugs delivery systems (DDS) have gained relevance in the field of nano- and bio-medicines.

PAMAM dendrimers G4.0 and G4.5 are optimal polymers as DDS that would increase the solubility of CBZ and the arrival to the brain.

Our objective was to characterize complexes between CBZ and dendrimers and to study their nanotoxicity. *In vitro* toxicity in human red blood cells was analyzed by hemolysis and in cell culture by colorimetric methods (MTT, crystal violet and neutral red). *In vivo* toxicity was studied in zebrafish animal model.

No hemolytic activity or morphological changes for any of the formulations were observed. As regards *in vitro* toxicity, different effects were observed for free drug, dendrimers and complexes, which allowed us to predict toxicity mechanism. *In vivo* toxicity showed no marked toxic effects between free drug and the complexes.

It has been developed a DDS based on dendrimers capable of efficiently transport the antiepileptic drug CBZ; what´s more, it is not toxic in *in vitro* and *in vivo* models.

Keywords: dendrimers, carbamazepine, cytotoxicity, zebrafish.

(375) **PROTEIN COATING DEFINES THE BIOLOGICAL IDENTITY OF NANOPARTICLES: RELEVANCE OF PROTEIN-PROTEIN INTERACTIONS.**

Cecilia Vasti, Laura Bonnet, Mauricio R Galiano, Ricardo Rojas, Carla E Giacomelli
INFIQC-CONICET, Departamento de Fisicoquímica. Facultad de Ciencias Químicas, Universidad Nacional de Córdoba.

Abstract: In the area of biomedicine, the use of nanoparticles (NPs) as carriers of therapeutic or theranostic agents has increased in the last years. Therefore, it is mandatory to understand the interaction between NPs and living organisms. In contact with biological fluids, the surface of NPs (synthetic identity) is covered with biomolecules (mainly proteins) that form a protein corona, which defines the biological identity. The protein corona formation is mediated by non-specific physical interactions, common to all molecular systems (van der Waals, electrostatics, etc.) as well as protein-protein interactions (PPI). This work is aimed at studying the protein corona formation on layered double hydroxides nanoparticles (LDH-NPs) previously modified with either albumin (LDH@ALB) or fetal bovine serum (LDH@FBS) and the cellular response of the biological identity. With such a purpose, LDH@ALB and LDH@FBS were dispersed in a protein containing cell culture medium, to compare the interfacial properties of the synthetic and biological identities and to characterize the protein corona. The interfacial properties were determined by dynamic light scattering measuring the size distribution and zeta potential. The molecules of the protein corona were identified by liquid chromatography coupled to mass spectrometry and the PPI network was evaluated with a novel approach, based on the bioinformatic tool STRING v.10.0 (http: //www.string-db.org/). The cellular response was evaluated through cytotoxicity and internalization experiments. We demonstrate that the protein corona formation was guided by PPI, through bioaffinity recognition, which led to different networks depending on the surface properties, defined by the protein coating. Furthermore, LDH@ALB and LDH@FBS are not cytotoxic and both present high levels of cellular internalization.

Keyword: protein corona, biological identity, PPI network.

Emma Cuello (1), Jesica Pereyra (1), César Barbero (1), Horacio Salavagione (2), Diego Acevedo (1), Edith Yslas (3)
(1) Departamento de Química, Facultad de Ciencias Exactas, Fisicoquímicas y Naturales, Universidad Nacional de Río Cuarto, Río Cuarto, Argentina, (2) Departamento de Física de Polímeros, Elastómeros y Aplicaciones Energéticas, Grupo de física de polímeros, Instituto de Ciencia y Tecnología de Polímeros, Madrid, España, (3) Departamento de Biología Molecular, Facultad de Ciencias Exactas, Fisicoquímicas y Naturales, Universidad Nacional de Río Cuarto, Río Cuarto, Argentina.

The objective of this work, was synthesized, characterized and evaluated the antimicrobial activity of tetracycline (tet) loaded in hydrogel nanocomposites containing graphene oxide (GO) and GO plus carbon nanotubes (CNT). The preparation of poly(N-isopropylacrylamide) (PNIPAm) hydrogel nanocomposites containing GO and GO plus CNT in the polymer network is communicated. This one-pot preparation methods include the dispersion of GO (or GO plus CNT) in a solution of monomers and the subsequent polymerization. The texture of the nanocomposites was studied using scanning electron microscopy (SEM), where very compact surfaces are observed suggesting good dispersion of GO sheets and CNTs within the polymer matrix. In order to apply these materials for antibiotic delivery, the absorption of tetracycline (tet) is evaluated and the nanocomposites showed better absorption capability and improved antibiotic delivery. This result showed that the loading capacity to incorporate an antibiotic is around 50 % higher for the composites than for the pristine hydrogel. The *in vitro* antibacterial properties of composite hydrogels were investigated by agar diffusion tests against gram-negative *Pseudomonas aeruginosa* bacteria. Besides, the agar diffusion test demonstrates the composite antimicrobial activity against *Pseudomonas aeruginosa* of tet loaded composite hydrogels (PNIPAm with graphene oxide and tet and PNIPAm with GO and CNT and tet). The results clearly show that the inhibition zone around each loaded composite PNIPAm-GO-tet (1.60 ±0.2 cm) and PNIPAm-GO-CNT-tet (1.75±0.3 cm) are higher than the PNIPAm-GO and NIPAm-GO-CNT without the antibiotic which not present inhibition zone. These results suggest that tet loaded PNIPAm-GO and PNIPAM-GO-CNT display antimicrobial activity against the *Pseudomonas aeruginosa* turning these materials as potential candidates for biomedical applications.

Keywords: hydrogels composites, bacterial inactivation, *Pseudomonas aeruginosa.*

(277) **AUTOREGULATORY ROLE OF THE KINASE A ACTIVITY IN CHROMATIN REMODELING OF *TPK1* SUBUNIT PROMOTER IN *SACCHAROMYCES CEREVISIAE***

Fiorella Galello, Constanza Pautasso, Sol Reca, Lucas Ojeda, Paula Portela, Silvia Rossi
Depto Qca Biológica, FCEN, UBA; IQUIBICEN-CONICET

Chromatin remodeling at gene promoters plays a critical role in initiation of transcription and the dynamics of chromatin structure are tightly regulated during this event. This process is performed by a large class of ATP-dependent chromatin remodeling complexes. *S. cerevisiae* PKA is composed by two catalytic subunits encoded by *TPK1*, *TPK2* and *TPK3* genes, and two regulatory subunits, encoded by *BCY1* gene. Previous results of our group indicate that a negative mechanism of isoform dependent autoregulation directs *TPKs* and *BCY1* gene expression and that *TPK1* promoter activity is positively regulated during heat shock. In order to understand the mechanism by which *TPK1* promoter is activated by PKA and its relation with heat stress, the regulation of chromatin remodeling by PKA during heat shock was investigated. First, we studied the nucleosome positioning using MNase assay, and three positioned nucleosomes were detected in *TPK1* promoter. Dramatic changes in chromatin structure were observed upon stress in wild type strain and in *tpk1^{w1}BCY1*, a strain with a very low PKA activity. The results indicate that the upregulation of *TPK1* promoter by a low PKA activity correlates with a remodeling in the promoter chromatin. PKA isoform specificity in remodeling of *TPK1* promoter was evaluated assessing: 1-TPK1 promoter activity in strains expressing only one of the three catalytic subunits using β-galactosidase reporter assay; 2-mRNA levels measurement by RT-qPCR and 3- the nucleosome positioning. The results indicate that Tpk2 isoform has the major inhibitor effect on *TPK1* promoter. Heat stress response is maintained in all strains. The results also show that yeast strains expressing only Tpk2 or only Tpk3 subunits lost the positioned nucleosome +1 on *TPK1* promoter. The recruitment of Tpk1 and Tpk2 catalytic subunits at *TPK1* promoter were assessed by ChIP assays. Our results point to a function for PKA activity in autoregulation of chromatin remodeling of *TPK1* gene

(417) **POST-TRANSCRIPTIONAL REGULATION AND mRNA LOCALIZATION OF PKA SUBUNITS IN *Saccharo-***

myces cerevisiae

Luciana Cañonero (1, 2), Constanza Pautasso (1, 2), Nicolás González Bardeci (1), Fiorella Galello (1, 2), Paula Portela (1, 2), Silvia Rossi (1, 2)
(1) Dpto. Qca. Biológica, FCEyN, UBA(2) IQUIBICEN-CONICET, Argentina.

In the yeast *Saccharomyces cerevisiae*, the protein kinase A (PKA) controls a variety of cellular events as a consequence of particular stimulus. The specificity of the cAMP signal transduction is maintained by several levels of control acting simultaneously. Our aim is to study the regulation of PKA subunits expression as one of such control levels, which is directed by the promoter's activity and the mRNA stability and localization. The balance among transcription, degradation and translation of individual mRNAs can be differentially regulated in response to environmental conditions such as heat stress. PKA holoenzyme from *S.cerevisiae* is composed by a dimer of regulatory subunit encoded by *BCY1* gene and two catalytic subunits encoded by *TPK1*, *TPK2* and *TPK3* genes. Previously we have shown that the promoter of each PKA subunit is differentially regulated during heat shock, particularly *TPK1* promoter is the only promoter activated. Here we demonstrate that *BCY1* mRNA half-life is longer than *TPK1* mRNA half-life and that *TPK1* and *BCY1* mRNAs are stabilized upon heat stress, as shown by Northern blot analysis. In contrast, Western blot analysis showed that Tpk1 protein abundance is not increased during heat shock. We also demonstrate that *TPKs* and *BCY1* promoter sequences can influence the levels of mRNAs abundance. *TPK1* mRNA localization was analyzed *in vivo* using the m-TAG methodology, showing the formation of ribonucleoprotein foci upon heat shock. Overall, the results suggest that in response to heat shock stress PKA subunit mRNAs increase their abundance and are concentrated in foci allowing a faster response once the environment is again favorable.

(1217) **PKA AND HOG1 ROLE ON GENE EXPRESSION IN RESPONSE TO OSMOSTIC STRESS IN S*ACCHAROMYCES CEREVISIAE***

Lucas Ojeda, Silvia Rossi, Paula Portela
Departamento de química Biológica, FCEN, UBA/IQUIBICEN - Conicet

Gene expression regulation by intracellular stimulus-activated protein kinases are essential for cell adaptation to environmental changes. The transcriptional induction of most genes whose transcription responds to salt stress is dependent on the association of the Hog1 kinase in stress-responsive genes that strongly correlates with chromatin remodeling and increased gene expression. Previously we described that PKA catalytic and regulatory subunits are associated with both coding regions and promoters of the several osmo-responsive genes in a stress dependent manner. Particularly, Tpk2 catalytic subunit activity regulates the chromatin remodelers Snf2 (SWI/SNF complex) and Arp8 (INO80 complex) association to promoters and coding regions to downregulate the gene expression during osmotic stress. Here, we focus on the interplay between PKA and Hog1 kinases on gene expression in response to osmotic stress. We tested for genetic interaction between *TPK2* and *HOG1* genes for cell survival to osmotic stress. While *tpk2*D mutant strain did not confer sensitivity to osmotic stress, *hog1*D mutant strain showed hypersensitivity to osmotic stress. The double mutant *hog1*D*tpk2*D displayed high tolerance to salinity suggesting that both kinase has an opposite role in cell adaptation to osmotic stress. ChIP assays showed a correlation in the *in vivo* kinetic recruitment of Tpk2 and Hog1 to *HSP42* coding region and *RPS29B* promoter region in response to osmotic stress, with a maximum at 5-10 minutes post-osmotic stress. We then analysed the nucleosome positioning at the promoter and coding region in *the RPS29B gene* by Micrococcal Nuclease (MNase) digestion of chromatin before and after stress in wild type. We found that osmotic stress, promotes an increase of compactness of the chromatin that correlated to downregulation of *RPS29B* gene expression. Our results suggest that transient stress adaptive response could be regulated by opposite roles of Hog1 and PKA.

Capacitation is the process by which mammalian sperm acquire the ability to fertilize and can be mimic *in vitro*. Once completed, sperm obtain acrosomal responsiveness and a hypeactivated flagellar movement.

When sperm are exposed to HCO^{3-}, there is rapid intracellular increase in cAMP, that activates PKA, which acts as a key player during capacitation. Its regulation has been mainly studied focusing on its **catalytic activity**. However, biological activity is also dependent on its **subcellular localization**, which is mediated by interaction with scaffolding AKAP proteins.

Here, we study the role of PKA anchoring **during** capacitation murine sperm. The binding and anchoring of PKA to AKAP was affected by the peptide st-HT31, which disrupts PKA-AKAP interaction without affecting catalytic activity.

When PKA anchoring was impaired ***throughout*** capacitation, sperm neither acquired acrosome responsiveness (assessed by PNA-staining of the acrosome), nor hyperactivated motility. Phosphorylation of PKA substrates as well as tyr phosphorylation were also blocked, as evaluated by western-blot.

Conversely, when PKA de-anchoring was induced in capacitated sperm, AR was triggered by a mechanism that involved 1) **membrane depolarization**, and 2) **Ca^{2+} influx**, seemingly through CatSper channel. These events were assessed by single-cell microscopy and population fluorimetric measures, using specific-sensitive dyes.

Addition of the inhibiting peptide st-HT31 induced AR only in capacitated sperm but not in non-capacitated cells, showing there are capacitation-associated events that prime the sperm for this response to PKA de-anchoring. In addition, AR needed active PKA activity, since inhibition of PKA right before st-HT31 exposure impaired AR. Moreover, an inactive analogue of st-HT31, named st-HT31p, did not show any effect.

Overall, we show that PKA anchoring is essential for its biological activity in sperm processes.

Carla Eliana Barraza, Pía, Germán Fernández, Silvia Moreno, Paula Portela
Universidad de Buenos Aires- CONICET, Depto Qca Biológica-IQUIBICEN, Ciudad de Buenos Aires, Argentina

Cellular responses to stress comprise a variety of different mechanisms, including translation arrest and the relocation of translationally repressed mRNAs to ribonucleic particles (mRNPs) like stress granules (SGs) and processing bodies (PBs). Given recent evidence on the role of liquid phase transition in signalling and cytosolic mRNPs formation, it is possible that SGs might represent regions where certain processes or the activity of enzymes are concentrated. Our results from biochemical approaches and microscopy analysis show that under mild heat stress the catalytic subunit of PKA isoform Tpk3 aggregates and promotes aggregation of eIF4G, Pab1 and eIF4E, whereas severe heat stress leads to the formation of PBs and SGs that contain the Tpk2 isoform and a larger 48S translation initiation complex. PKA affects the translational response to heat stress, where each Tpk catalytic isoform appears to have a different role, with Tpk2 and Tpk3 playing negative and positive roles in the translational response, respectively. We favour a model where depending on the severity of an external stimulus, such as

heat stress, each catalytic isoform of PKA interacts with a complex network of distinct protein factors and potential substrates.

Our ongoing studies are focused on a global characterization of protein complexes under different heat stress conditions. To this end, we performed a label-free quantitative proteomic analysis of granular enriched fraction from mild and severe heat stress using a QExactive. We identified proteins exclusively enriched in mild and severe heat stress, as well as proteins common to both groups. Gene Onthology analysis showed annotations associated with several GO biological processes, such as structural constituent of ribosome, RNA binding and translation factor activity. Networks built from these results will let us start defining how different degrees of severity of the same stress evoke a specific response on RNP assembly.

(1069) **A NOVEL PHOSPHATASE GOVERNS STRESS GRANULES' DYNAMICS**

Natalia Estefania Contreras, Marcelo Perez-Pepe, Graciela Lidia Boccaccio
Fundacion Instituto Leloir

Stress granules (SGs) are macromolecular aggregates of mRNAs and proteins that belong to a growing family of "liquid organelles". SGs are specific to the cellular stress response and form transiently upon acute stress.SGs are dynamic and exposure to polysome-stabilizing drugs such as cycloheximide induces SG disassembly, by "trapping" messengers in polysomes. We performed a high-throughput RNAi screen in Drosophila cells to identify novel signaling pathways that regulate SG dynamics. Here, we focus on the role of a novel phosphatase (NP) that showed a high score in the primary screen. We used fly and mammalian cell lines, specifically HEK293T and U2OS,exposed to arsenite, a well-known model of oxidative stress, in combination with imaging and RNAi. We found that NP KD increases SGs formation in both Drosophila and mammalian cells ($p<0.05$). Conversely, the overexpression of NP impairs SGs assembly ($p<0.05$).In addition, SGs formed in NP KD cells are resistant to cycloheximide-induced dissolution ($p<0.05$). We investigated the subcellular localization of NP in U2OS cells, and found that NP is mostly nuclear, and concentrate in discrete domains. NP is not present in speckles but SF2 -a speckle marker- partially colocalizes with NP nuclear domains. Polyadenylated RNA stained by FISH is excluded from NP domains. We wonder whether NP changes localization upon stress and/or if it is recruited to SGs. We found that the nuclear staining becomes homogeneous and the NP domains vanish. Also, we found that NP partially mobilizes to the cytosol, and is not significantly recruited to SGs. Finally, western blot assays revealed that NP levels rapidly decline immediately after the oxidative stress stimulus (60% of basal levels; $p<0.05$). We hypothesize that the degradation of NP triggered by stress facilitates SGs formation and, accordingly, the KD potentiates the response. Relevant NP targets are currently being investigated. We thank ANPCyT, CONICET and UBA, Argentina for funding.

(399) **PRE-EQUILIBRIUM PROPERTIES OF SIGNALING DOSE-RESPONSE CURVES ALLOW DISCRIMINATION BETWEEN NEGATIVE COOPERATIVITY AND INDEPENDENT BINDING**

Federico Sevlever, Juan Pablo Di-Bella, Alejandro Colman-Lerner, Alejandra Cristina Ventura
IFIBYNE

Previous works in cellular signaling propose to study pre-equilibrium properties in order to distinguish between negative cooperativity (NC) and independent binding (IB). We have already presented the existence of a mechanism known as Pre-Equilibrium Sensing and Signaling (PRESS), which allows cells to discriminate between signaling levels that saturate receptors in equilibrium.

In this work, we combine analytical-computational studies of two toy models of a ligand-receptor binding with two binding sites, one model presenting NC and the other, IB. Using statistical analysis of the parameters space, we have discovered Hill coefficient pre-equilibrium general properties whichallows to design new protocols of discrimination between NC and IB. We have tested the efficiency of these protocols for simulated data from both models and its dependency with noise from chemical reactions stochasticity.

We found that pre-equilibrium Hill coefficient adds information and improves previous discrimination protocols.

Keywords: Signaling, cooperativity, Hill coefficient.

(1377) **BIOCHEMICAL TRANSDUCTION MEDIATED BY AN AMPEROMETRIC SIGNAL: HORSE RADISH PEROXIDASE IMMOBILIZED IN A LAPONITE/POLYMER HYDROGEL**

A device composed by a biological receptor and a transducer is defined as a biosensor, where a biomolecule detects a substance and the transducer, interprets and "translates" the biological recognition reaction into a quantifiable signal. Both components are responsible for biosensor sensitivity and selectivity, as well as give rise the ability of direct and real time analysis. This work proposes the design and development of an electrochemical biosensor including the enzyme horseradish peroxidase (HRP) into matrices of mineral nanoparticles (Laponita®), gold nanoparticles (AuNP) and polymers of vinylbenzyl thymine and vinylbenzyl ammonium units (VBT-VBA). Hydrogels were prepared mixing laponite and polymer with different amounts of HRP and AuNP, deposited on a glassy carbon electrode surface. The biosensor experimental variables were optimized and the analytical characteristics were determined. The analytical signal was obtained by amperometry. The stability and the functionality of the hydrogel film are influenced by a mass/charge ratio resulting in a balance between the components involved. The optimal composition of the hidrogel was: 30 µg laponite + 15 µg polymer + 15 µg HRP and 2.5 µl AuNP solution. The immobilization of the biomolecule is fundamental in the design and development of a biosensor and the laponite demonstrated optimal qualities in this sense. On the other hand, the thymine biopolymers make possible the stabilization of these structures and the AuNP improve the current signal increasing the conductivity of the hydrogel, this produce suitable microenvironments in which the biomolecules can retain their biological and biocatalytic activity. The developed biosensor showed outstanding characteristics, reason why it is potentially applicable to the analysis of real samples.

(1571) **BIOENGENEERING OF THERMOSENSORS**

Daniela Belén Vazquez, Juan Cruz Almada, Juan Manuel Villalba, Ana Bortolotti, Larisa Estefanía Cybulski
Departamento de Microbiología. Facultad de Ciencias Bioquímicas y Farmaceúticas. Universidad Nacional de Rosario

Living organisms are exposed to changes in their environment and the ability to adapt to such changes is crucial for survival. Adaptation to temperature changes has particular importance in poikilothermic organisms such as bacteria, plant and fish. Two-component systems (TCS) are tools that bacteria employ to detect changes in their environments and execute an adaptive response. Understanding the molecular and biophysical bases of bacterial signal transduction is key for drug design and biotechnology. DesK / DesR TCS from *B. subtilis* is involved in adaptation to temperature changes. Using this system as a model we study the mechanism of temperature perception of the histidine kinase DesK containing five transmembrane segments (TMS). To address this challenge, we constructed a chimerical protein that presents a single TMS but retains the ability to detect temperature and membrane fluidity. We focus on responding: What mechanism uses DesK to control gene expression? What is the difference between a sensor TMS and a structural TMS? Do

regions of the protein that are not involved in the thermodetection respond to any other stimulus? We have identified three determinants of thermodetection that allow to activate the catalytic domain of DesK. We retuned these determinant of thermodetection to improve the sensing capacity and incorporated them into an inert poly-valine scaffold and recovered activity. The significance of this work is that the designed sensors function as a modular reversible system, which can be incorporated into different genetic circuits to control the expression of genes in the study of cells. This is relevant in medicine and industry, because the temperature is an important tool to manipulate gene expression, which allows cells to be stimulated reversibly and non-invasively to generate responses of interest.

(330) **INVOLVEMENT OF WNT/ β-CATENIN INHIBITION IN OVARIAN CANCER CELL LINES PROLIFERATION AND APOPTOSIS**

Sebastian Bocchicchio, Marta Tesone, Griselda Irusta
Instituto de Biología y Medicina Experimental (IByME).

Wnt/β-catenin is a highly conserved pathway which regulates proliferation, apoptosis and differentiation. While it has been demonstrated to participate in cell growth of different biological systems, no studies have been performed in ovarian cancer cell growth regulation. To evaluate the involvement of Wnt/β-catenin pathway in ovarian cancer cell proliferation and apoptosis, two human epithelial ovarian cancer cell lines (IGROV-1 and SKOV-3) were incubated in the presence of a Wnt inhibitor ICG-001). The cells were incubated in the presence of ICG-001: 1, 10, 20 and 50 μM or with no stimulus (control). After 48hs of incubation, we harvested the cells to count them and we performed protein extracts for western blot technique. We also determined apoptosis by citometry: cells were double-stained with Annexin V-fluorescein isothiocyanate (FITC) and propidium iodide (PI).

Our results showed a substantial and dose dependent decrease in proliferation when both cell lines were incubated in the presence of ICG-001. We also observed a decrease in protein levels of Wnt/β-catenin and CyclinD1, when cells were treated with the inhibitor (with all the concentration used). Regarding to apoptosis, we observed a low percentage of apoptotic cells (<5%) among cells treated with 1μM ICG-001 and the control group. The percentage of apoptotic cells notably increased (> 25%) in cells incubated with 20 and 50 μM ICG-001.

In conclusion, we demonstrate that Wnt/β-catenin signalling regulates ovarian cancer cell lines proliferation and apoptosis.

(956) **A VIEW ON PROTEIN CONFORMATION BY GENERAL METHYLATION OF SURFACES. AN NMR APPROACH.**

Evangelina Marisel Bernar (1), Gabriela Elena Gómez (1), Clara Smal (2), Martín Arán (2), José María Delfino (1)
(1) Departamento de Química Biológica e IQUIFIB (UBA-CONICET), Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, (2) Fundación Instituto Leloir

Abstract: The solvent accessible surface area (SASA) of the polypeptide chain plays a key role in protein folding and interactions. However, this fundamental parameter eludes direct analysis. Our approach involves the reaction of the minimal photochemical reagent diazirine (DZN) with polypeptides. Because of its size, DZN (i) mimics water, and (ii) shows narrow chemical selectivity, due to the extreme reactivity of methylene carbene (MC). Detection of products by NMR benefits from the fact that it does not demand cleavage of the polypeptide. The extent of MC reaction at various sites across the surface of E. coli thioredoxin (TRX) was assessed. The preservation of conformation and stability of the labeled samples was evaluated by circular dichroism (CD) and fluorescence emission. The dominant phenomenon involves methylation of amino acid side-chains, as attested by the enrichment of the aliphatic region in ^{1}H-NMR spectra. In the unfolded state, an enhanced and broad methylation profile points to extensive solvent exposure. ^{1}H-^{13}C-HSQC spectra of native TRX reacted with ^{13}C-DZN reveal new cross-peaks corresponding to water-exposed methyl groups. ^{1}H-^{15}N-HSQC spectra reveal the different impact of the reaction on backbone amide environments. The relative intensity of CHα spots is indicative of the extent of methylation at individual amino acid residues. Moreover, CHβ, CHγ and CHδ cross-peaks pinpoint details of side-chain modification. A fully consistent pattern emerges from both HN and HC profiles. Outer as well as inner (cavity) surface components become prime targets of methylation. Because of its mild reaction conditions and strong emphasis on side-chain modification, the MC labeling approach emerges as a distinctive footprinting method. All in all, the newly gathered spectral data highlights a rich panorama on protein conformation.

Keywords: protein conformation, solvent accessible surface area, footprinting technique, NMR, thioredoxin.

(489) **CONFORMATION AND STABILITY OF A RECOMBINANT VARIANT OF HUMAN FRATAXIN PRECURSOR**

Ignacio Hugo Castro, María Georgina Herrera, Martín Ezequiel Noguera, Javier Santos
Institute of Biological Chemistry and Physical Chemistry (IQUIFIB) Dr. Alejandro Paladini, University of Buenos Aires, Buenos Aires, Argentina.

Abstract: Friedreich´s Ataxia is a disease caused by a decrease in the expression frataxin (FXN) and loss of FXN functionality. The outcome of the lack of FXN function is an inefficient iron-sulfur cluster assembly, with widespread enzymatic deficit and oxidative damage. FXN is translated in the cytoplasm as a precursor of 210 residues (FXN1-210). Then, this protein is imported into the mitochondrial matrix and processed to the mature form (FXN81-210). One outstanding strategy to increase the concentration of active FXN inside mitochondria involves the production of recombinant variants with the capability of crossing cell membranes, thus yielding an active and stable form of the protein.

We investigated the conformation and folding of the recombinant precursor variant His6-TAT-FXN1-210 that includes a cell-penetrating peptide (TAT) in the N-terminal region (NTR) and a His tag. We studied the thermal unfolding process by circular dichroism (CD). Results showed unfolding is not reversible unless a given GmdCl concentration is added to the protein sample. In this case, the process is completely reversible. Neither urea nor NaCl exhibit the complete effect observed for GdmCl, but a combination of both does it. These results suggest that (i) the NTR establishes interactions favoring FXN aggregation; (ii) aggregation is enhanced at high temperatures but may be attenuated by the presence of additives; and (iii) NTR-mediated interactions are of both sorts: ionic and apolar.

His6-TAT-FXN1-210 was studied by light scattering. It is mainly monomeric and, at subdenaturing concentration of GdmCl, it exhibits a R_h larger than the expected for fully-folded protein. According to this, Far-UV CD spectra and secondary structure predictions suggest that the NTR is disordered. To know whether His6-TAT-FXN1-210 is active, we performed a NFS1 activation assays. Results suggest that FXN function is conserved in this variant.

(3) Departamento de Biología Integrativa, IGBMC, CNRS, INSERM, Universidad de Strasbourg, Illkirch, Francia.

Hypoxanthine phosphoribosyltransferase (HPRT) is the key enzy-

me of the purine salvage pathway. It is essential for the survival of trypanosomatids, organisms that -unlike humans- cannot benefit from de novo nucleotide synthesis. As such, this enzyme has been proposed as a potential target for drugs aimed at treating parasitic diseases. This study underscores the effect of different ligands on the structure, stability and function of T. cruzi HPRT (TcHPRT). Light scattering experiments indicate that the protein adopts a tetrameric arrangement. Interestingly, proteolytic removal of the C-terminal region (CTR) yields a well-defined dimer showing somewhat increased activity. Considering that TcHPRT is imported to glycosomes, one can hypothesize that once inside the organelle, the CTR -which includes the import signal- could be excised giving rise to the dimer. The activating effect observed at low concentrations of olpadronate and ibandronate, bisphosphonates (BPs) analogues of the substrate phosphoribosyl pyrophosphate, is more evident for the tetramer than for the dimer. Correspondingly, their inhibitory action at high concentrations is less marked for the former. These facts fall into place in our proposed cooperative model for the activity of this oligomeric enzyme. Strikingly, the inhibitory effect is essentially null when assayed against human HPRT. To assess the action of these small molecules within a cellular environment, we exposed cultures of epimastigotes to selected BPs, demonstrating significant growth inhibition. To visualize the enzyme forms that might be interacting with those ligands, we expressed both proteins in Leishmania tarentolae as fusion constructs with GFP. Western blot analyses reveal that TcHPRT is not processed to a shorter form in this system. This new molecular and cellular knowledge becomes most relevant for the design of innovative parasite-targeted therapeutics.

Abstract: Oxidation of methionine side chains, which has been traditionally perceived as damage derived from oxidative stress, is now emerging as a post-translational modification capable of regulating protein activity and cellular processes such as the activation of Ca^{2+}/Calmodulin dependent kinase II or remodeling of the acting cytoskeleton. Methionine oxidation leads to two diastereomers known as the R and S forms of methionine sulfoxide (MetOx). In vivo, MetOx is reduced back to methionine by two families of stereospecific and conserved methionine sulfoxide reductases, MSRA and MSRB, which specifically target protein-bound MetOx-R and -S isomers, respectively. Methionine oxidation is amongst the most difficult-to-study post-translational protein modification in vivo because sulfoxides are not easily detected with chemical probes or antibodies and because they spontaneously form during sample preparation for mass spectrometry. By contrast, MetOx display unique NMR signals, including different sets of resonances for its R and S isomers that are readily identified in the NMR spectra. In order to assess the role of MSRs in cellular function we ought to monitor their activities in vivo with high resolution. In this work we designed an NMR based assay to simultaneously delineate MSRA and MSRB reductase activity in vitro and in cell extracts and validated its use for further in vivo studies using In-cell NMR methodologies. Our results showed that MSRA is more active than MSRB in E. coli cells and those bacteria have free MetOx reduction activity, in line with previous reports. We expect that our results will open new research paths to expand the repertoire of MetOx-regulated signaling pathways and to further understand the role of MSRs in physiology and pathology.

(474) **NEW INSIGHTS ON ICA512 AND INSULIN INTERACTION**

Pamela L. Toledo (1), Juha M. Torkko (2), Ramiro E. Llovera (1), Andreas Müller (2), Michele Solimena (2), Mario R. Ermácora (1)
(1) Instituto Multidisciplinario de Biologia Celular, CONICET, Argentina; Universidad Nacional de Quilmes. (2) Molecular Diabetology, Faculty of Medicine, TU Dresden, Germany; Paul Langerhans Institute Dresden of the Helmholtz Center Munich at the University Hospital and Faculty of Medicine of TU Dresden, Dresden, Germany; German Center for Diabetes Research (DZD e.V.), Neuherberg, Germany.

Abstract: ICA512/IA–2/PTPRN is a decoy receptor protein tyrosine phosphatase enriched in secretory granules (SGs) of the pancreatic β-cells and other neuroendocrine cells. Previous studies imply its involvement in the biogenesis, trafficking and exocytosis of insulin SGs, as well as in β-cell proliferation. Its regulated endocrine-specific protein 18 homologous domain (RESP18HD) is necessary and sufficient for the sorting of ICA512 to SGs of rat insulinoma INS-1 cells and its binding with high-affinity to insulin and proinsulin. In previous studies we observed the formation of complexes between insulin and RESP18HD 35-131 by co-aggregation in vitro. We now show by EM negative staining that complexes of insulin and RESP18HD are amorphous, in contrast to RESP18HD alone, which instead self-aggregates in a moderately ordered fashion. ICA512-RESP18HD consists at least two distinct regions, including a N-terminal Cys-rich motif (aa 35-90) and an intrinsically disordered region in the C-terminal part of the domain (aa 91-131). Fluorescence microscopy of RESP18HD-TQ2 tagged fusion protein variants in INS-1 cells shows that the region encompassing the signal peptide (aa 1-34) followed by the Cys-rich motif of the RESP18HD (aa 35-90) contains sufficient information for SG targeting. Moreover, co-expression of different RESP18HD-TQ2 variants with Insulin-Venus fusion to assess Fluorescence lifetime imaging-fluorescence resonance energy transfer (FLIM-FRET), revealed moderate interaction (FRET) of these proteins also in the cells. These results further underscore the enabling role of ICA512-RESP18HD in targeting insulin and possibly other cargoes to the SGs.

(1179) **SOLUBLE LIKE STRUCTURE-FUNCTION OF β-GAL DESORBED FROM INCLUSION BODIES**

Sandra Soledad Flores Mamani, Maria Veronica Nolan, Julieta Maria Sanchez, Maria Angelica Perillo
Instituto de Investigaciones Biológicas y Tecnológicas (IIByT), CONICET Cátedra de Química Biológica, Departamento de Química, Facultad de Ciencias Exactas, Físicas y Naturales, FCEFyN, Universidad Nacional de Córdoba.

Bacterial inclusion bodies (IBs) are mesoscopic protein aggregates commonly observed in transformed bacteria, primarily formed by recombinant proteins. Historically, IBs have been considered a hurdle for the production of soluble protein species, and many genetic and process-based strategies have been developed to minimize their formation. However, recent research has described the use of IBs as functional materials usefull as reusable catalysts, drug delivery systems, and functional topographies in tissue engineering [1]. We have proved that β-galactosidase (β-Gal) IBs ($IBs_{\beta\text{-}Gal}$) can be found in an amyloidal form which holds in non-amyloidal functional proteins with some particular stability properties. Also, we have demostrated that β-Gal desorbes spontenously from IBs in low osmotic pressure media (achieve by successive dilutions). In this work we study the structure/function relationship of the desorbed β-Gal ($\beta\text{-}Gal_D$). By means of intrinsic fluorescence, infrared spectroscopy (IR) and enzymatic activity experiments we have got evidence that $\beta\text{-}Gal_D$ retains the structural/functional properties of the soluble protein. Furthermore, by means of IR and DLS experiments in real time, we have found that while $\beta\text{-}Gal_D$ is spontaneously released from the aggregates a reorganization of IBs occurs. This results demonstrate that the IBs isolation and the concomitant dilution steps of this sample is a simple and a proper methodology to obtain active protein. Hence, the nature of the recombinant protein and the conditions for IBs formation and isolation determine the success of the desorption of the protein in a soluble-like conformation.1.Rinas, U., et al., Bacterial Inclusion Bodies: Discovering Their Better Half.Trends in

BiochemicalSciences, 2017.

(497) **STUDY OF INTERDOMAIN INTERACTIONS THROUGH THE USE OF PARAMAGNETIC TAGS**

Florencia Carla Mascali, Rodolfo M Rasia
Instituto de Biología Molecular y Celular de Rosario

Micro-RNAs (miRNAs) are a class of small endogenous RNAs that negatively regulate the expression of mRNAs through the recognition of complementary sequences. Proteins with double stranded RNA binding domains (dsRBD) are essential in miRNA biogenesis. These proteins recognize pri-miRNA precursors in plants lacking conserved sequences. However, this process is not well characterized. With the aim of understanding the process of recognition of this type of domains, we decided to carry out a structural study of the two dsRBDs domains of HYL1 from Arabidospsis thaliana. The N-terminal portion of HYL 1 containing two dsRBD domains connected by a native loop is sufficient to complement the hyl1 mutant phenotype. We generated constructs with 14 residue lanthanide-binding tags (LBTs) at each end of either domain, and performed PRE (Paramagnetic Relaxation Enhancement) experiments by measuring the signal intensity for each residue in the protein loaded with either Lu(III) as diamagnetic control, or Gd(III), a paramagnetic metal. Unpaired electrons in Gd(III) cause an increase in the relaxation velocity of nearby nuclei as a function of the distance to the metal. Based on the results obtained in each domain, we modeled the dynamics allowed by the loop that connects them. We observed that the movement of the domains is not completely random, and that there is a predisposition for forms connecting the N-terminal end to the second dsRBD domain. Once free system is fully characterized, the complex between these proteins and miRNA precursors will be further studied, in order to better understand how these domains recognize their substrate and thus precisely position the active site of the complex in the precursor.

Keywords: PRE (Paramagnetic Relaxation Enhancement) LBT (Lanthanide Binding Ta) dsRBD (Double-stranded RNA-binding domain)

(1227) **SURFACE EVALUATION TECHNIQUES TO CHARACTERIZE "DE NOVO" DESIGN ANTIMICROBIAL PEPTIDES**

Patricia Maturana (1), Mario Felicio (2), Melina Martinez (3), Juan C Espeche (1), Sonia Gonçalves (2), Nuno C Santos (2), Liliana Semorile (3), Paulo Maffia (3), Axel Hollmann (1)
(1) CITSE UNSE-CONICET, Santiago del Estero, (2) Instituto de Medicina Molecular, Lisboa, Portugal, (3) Laboratorio de Microbiología Molecular, IMBA, UNQ, Bernal.

Conventional antibiotics are facing strong microbial resistance that has recently reached critical levels. This situation is leading to a reduced therapeutic potential of a huge proportion of antimicrobial agents currently used in the clinic. Antimicrobial peptides (AMPs) could provide the medical community with an alternative strategy to traditional antibiotics for combating microbial resistance. However, fully understand their mechanisms of action and promote the reduction of the unwanted toxicity remains as a critical step to consider these compounds to be a therapeutic promise and overcome clinical setbacks. In this context, this work focused on unravel the way of action of de novo designed AMPs by using surface evaluation techniques as Surface Pressure, Surface Plasmon Resonance (SPR) and Atomic Force Microscopy (AFM). Surface pressure results obtained well correlate the highest affinity toward negatively charged membranes with the lowest CIM values. Whereas SPR technique that allows to obtain association (ka) and dissociation (kd) constants and calculate the fraction of the peptide that remains bound to the lipid membranes after dissociation (Rb), allows to dissect the kind of interactions. SPR results showed that beside the importance of a high membrane affinity, that allow the peptides reach the membrane, this Rb parameter complements the analysis and helps to clarify misinterpretations of the Kd data, confirming that Is also important that peptides remained strongly bound to membranes (i.e. high Rb). Finally, by AFM we were able to visualize the effects of AMPs directly on the bacterial cells. Error and height images showed that after 1h of peptide incubation, bacteria surface was severely damaged and leakage of intracellular media was also observed.

Overall, our studies focus on understanding possible relations between AMP–membrane interactions and the efficiency of these drugs, offering a rational basis for the improvement of these compounds.

(1416) **TFE UNVEILS THE EXISTENCE OF INTERMEDIATE SPECIES IN INTESTINAL FATTY ACID BINDING PROTEIN (IFABP), A CLASSICALLY RECOGNIZED TWO STATE PROTEIN MODEL**

Allan Nicoleyson, Carla Angelani, José María Delfino, Lucrecia Curto
Instituto de Química y Fisicoquímica Biológicas "Prof. Alejandro PaladinI" (UBA-CONICET), CABA, Argentina.

IFABP is a 15 kDa protein exhibiting a β-barrel fold that resembles a clamshell consisting of two perpendicular five-stranded β-sheets with an intervening helix-turn-helix motif between strands A and B. Despite the fact that naturally occurring β-sheet proteins avoid aggregation through a variety of strategies, the addition of high concentrations of a structure-promoting cosolvent such as 2,2,2-trifluoroethanol (~ 25% v/v TFE) induces conformational rearrangements that trigger the onset of amyloid-like aggregation. Previous work from our group revealed that, in equilibrium, low concentrations of TFE (up to 15 % v/v) foster conformational changes akin to those leading to aggregation-prone species. Most significantly, the protein remains functional as attested by its capacity to bind fatty acids. As retaining function is a signature of the native state, it can be concluded that this level of co-solvent favors the population of alternative conformations scarcely explored in water. In view of this fact, we decided to evaluate which were the most relevant conformational rearrangements.

Hardly any structural change in IFABP is observed by the full preservation of secondary structure and the minimal perturbations in tertiary structure, evidenced by the circular dichroism (CD) spectra and the unaffected λmax of fluorescence emission. Strikingly, even TFE concentrations as low as 2.5% turn the protein susceptible to thermal irreversible unfolding. Interestingly, data derived from guanidinium chloride-induced equilibrium unfolding transitions reveal the population of an intermediate species. This result demonstrates for the first time that IFABP does not follow a simple two-step folding behavior in equilibrium. Full characterization of this hidden intermediate might shed light on the genesis of aggregation-prone species.

The fatty-acid-binding proteins (FABPs) act as intracellular lipid chaperones. The structure is a beta barrel surrounding an inner cavity that accommodates fatty acids, enabling their transport in an aqueous media inside the cell. But the mechanism of lipid binding and release is still the topic of many studies. This exchange involves at least three stages: opening a portal at the protein surface, ligand entry/release, and portal closure. It is challenging to obtain experimental evidence on the functionality of the portal without modifying the amino acid sequence or the protein conformation. Studying these processes in the crystallized protein opens a unique possibility, because when confined in the crystalline network the conformational changes are limited by the crystal packing. We soaked a FABP-Palmitic acid crystal with Br-palmitic acid, using the heavy Br atom as a marker. After solving the structure at 1Å resolution, we observed

Br-palmitic acid inside the cavity, proving that ligand exchange does take place in the crystal. However, the crystal structure does not differ significantly from the already resolved structures, and does not show details of the ligand exchange. Since the accuracy of our structure provides a reliable starting point for Molecular Dynamics simulations, we build a model of 2 unit cells (8 proteins), and properly choosing the simulation box, we model the whole crystal by means of the periodic boundary conditions. After 2 μs of simulation at constant volume (NVT ensemble), the computational results correctly describe experimental behavior. MD simulation shows details of possible pathways for lipid release that are not visible by diffraction techniques, independently of their quality. Therefore, this simulation provides a complementary methodology to fill in the gaps left by the crystallographic images of the conformational average. The joint use of diffraction techniques at subatomic resolution, and molecular dynamics from reliable models, are consequently confirmed here as a powerful set of tools.

Seeds are of great economic interest due to the value of their organic composition. The metabolic pathways leading to the deposition of triacylglycerols and proteins in seeds are complex in terms of the amount of enzymes involved, regulatory context and variability between species. Previous studies of our group indicated that NAD- and NADP-dependent malic enzymes (ME) participate in the provision of reducing power and citrate or acetyl-CoA, respectively, to the pathways of reserve biosynthesis during soybean maturation. In this context, the aim of this work was to analyze the biochemical and regulatory properties of the enzymes belonging to this family. For this, the different ME isoforms were obtained through cloning, heterologous expression in *Escherichia coli* and subsequent purification. Our results indicated that the only plastidic NADP-ME detected in seeds has a high affinity for its substrates malate and NADP. Furthermore, it is activated by glutamine, the main nitrogen compound that is imported to the seed to support the synthesis of reserves. On the other hand, the mitochondrial NAD-ME isoforms also showed an important positive regulation by metabolites present in the seed, being NAD-ME2.4 (the product of the most abundant transcript throughout the filling) the most regulated. The activation by fructose-1,6-bisphosphate and phosphoenolpyruvate, both produced during irreversible steps of glycolysis, indicates a coordination between this pathway and the malate metabolism. In turn, the activation of NAD-ME proteins by CoA and acetyl-CoA suggests their involvement in fatty acid biosynthesis. These findings provide new insights into intermediary metabolism in oilseeds and nominate ME as new biotechnological tools to be used in breeding programs.

Keywords: intermediate metabolism, malic enzyme, oilseeds, proteins, lipids

(816) MUTATIONAL APPROCHES TO OBTAIN LOCKED CONFORMATIONS OF THE BACTEROIPHYTOCHROME FROM THE PLANT PATHOGEN *XANTHOMONAS CAMPESTRIS*

Giuliano Tomás Antelo (1), Sebastián Klinke (1), Maximiliano Sánchez (1), Fernando Alberto Goldbaum (1), Lisandro Otero (1), Hernán Ruy Bonomi (1), Jimena Rinaldi (1)
(1) Fundación Instituto Leloir - IIBBA CONICET, Buenos Aires, Argentina.

Light modulates the host-microbe interaction and several virulence-related phenotypes in the plant pathogen *Xantomonas campestris*. This is mediated by its bacteriophytochrome, XccBphP.

Bacteriophytochromes are photoreceptors found in bacteria that bind biliverdin (BV) as their chromophore. They typically present a red-absorbing form (Pr) and a far-red absorbing form (Pfr).

XccBphP is a bathy-like phytochrome. This means that it exhibits a dark conversion from Pr to Pfr, reaching an equilibrium Pfr:Pr ratio of 85:15 (pH 7.7) with a half-life of 7.45 h.

XccBphP presents at the N-terminus a PAS2-GAF-PHY domain triad as its photosensory module, and a PAS9 domain as its output module. In order to get insight into the light-dependent activation mechanisms, the crystal structure of the full version of XccBphP was recently solved by our group. The solved structure shows a parallel homodimer arrangement along a central helical spine in the Pr state.

With the aim of obtaining XccBphP versions locked in Pfr or Pr states to perform molecular, structural and physiological studies, we are carrying out rational and random mutagenesis approaches in several key positions likely to affect its photochemical behavior. The analysis is accomplished by UV-VIS spectroscopy.

By this means, we have identified the mutant G454E, which exhibits a 100% Pfr conversion in the dark. This is reminiscent of the monomeric ΔPAS9 mutation. Hence, we performed a static light scattering determination of its molecular weight. The results show that the oligomeric state of the mutant is a dimer. Thus, we have obtained a full-length dimeric variant with a stable (but not locked) Pfr state.

Currently, a crystallogenesis screening of XccBphP G454E in dark conditions is being performed. We hope to obtain a crystal structure in the Pfr state to compare it to the already solved structure and elucidate the light-driven conformational changes.

Keywords: Xanthomonas campestris; bacteriophytochrome, biliverdin

(836) DISSECTING THE MOLECULAR PROCESS OF N-END RULE SUBSTRATE RECOGNITION AND DELIVERY TO CHAPERONES BY THE CHLOROPLASTIC N-RECOGNIN ATCLPS1

Dianela Aguilar Lucero (1), Clara Colombo (1), Eduardo Ceccarelli (1), Germán Rosano (1)
(1) Instituto de Biología Molecular y Celular de Rosario.

Proteolysis is one of the main strategies for proteostasis maintenance. In chloroplasts of *Arabidopsis thaliana*, the caseinolytic protease (Clp) is the main proteolytic system. It is composed by the protease ClpPR (a complex of 9 different proteins), the Hsp100 unfoldases ClpC1/2 and AtClpS1, an N-recognin who mediate substrate recognition. N-recognins identify structural features in the N-terminal end of the target, a process known as the N-end rule. Bacterial ClpS is extensively characterized, mainly due to the possibility of reconstituting the bacterial Clp system *in vitro* and evaluating the degradation of fluorescent targets, a strategy that could not be replicated for the chloroplast system. To unravel the specificity of the plant proteolytic machinery and to exploit the usefulness of the *in vitro* activity of the bacterial system, we rationally designed five chimeric proteins using the AtClpS1 backbone, exchanging different pieces of its sequence with the corresponding part of bacterial ClpS. We focused specially on the parts that mediate binding to the bacterial chaperone with the ultimate goal of obtaining a fully functional bacterial system but with plant specificity. The five chimeras were successfully obtained in recombinant form and purified. Preliminary results show that the N-terminal end of AtClpS1 is essential for substrate delivery, as the chimera NtEcClpS::Nt-AtClpS1 greatly inhibited the degradation of fluorescent substrates. Yet in another approach, we designed an AtClpS1 protein, where the predicted AtClpS1 amino acids involved in Hsp100 interaction were mutated. Pull down experiments showed that these amino acids are crucial for AtClpS1 and ClpC2 interaction. This mutant will be used to fish out substrates from the chloroplast stroma and sequence their N-terminal end. Our work provides new molecular tools to unravel the N-end rule in chloroplasts.

(841) PROBING THE SPECIFICITY OF THE CHLOROPLASTIC N-RECOGNIN ATCLPS1 WITH FLUORESCENT PROBES BEARING DIFFERENT N-TERMINAL ENDS

Alejo Cantoia (1), Eduardo Ceccarelli (1), Germán Rosano (1)

(1) Instituto de Biología Molecular y Celular de Rosario.

Proteolysis is a highly regulated process as useful proteins must not be inadvertently eliminated. One of the mechanisms of target selection for degradation is recognition of N-degrons by an N-recognin. An N-degron is structural feature of the N-terminal end which is recognized by proteins (N-recognins) that deliver the target to a protease o mark it for degradation. In bacteria, the N-recognin ClpS recognizes destabilizing amino acids in the N-terminus, like Phe, Tyr, Trp and Leu, binds to the substrate and presents it to the ClpAP protease. Binding of ClpS is also enhanced by positive charges in second position; proteins starting with Phe-Arg (FR) are degraded within seconds. In chloroplasts of *Arabidopsis thaliana*, a homolog of bacterial ClpS has been found (AtClpS1) so it is believed that proteolysis of chloroplastic proteins is similar, although experimental evidence is lacking. Moreover, previous results by our group have shown that the specificity of AtClpS1 is different from bacterial ClpS as positive charges in second position seem to be detrimental for recognition. We created fluorescent probes to survey the specificity of AtClpS1, as it was done for bacterial ClpS. The N-terminal end of the green fluorescent protein was mutated to FR/FE/EE/EL and SA, being the last two N-terminal ends from two proposed natural substrates. The fluorescent probes were obtained in recombinant form and purified to homogeneity. By pull down assays and fluorescence anisotropy experiments, we show that AtClpS1 can bind to substrates with negative charges in the first and second position. This is the first experimental evidence of an N-recognin of the ClpS family with predilection for negative charges at or near the N-terminal end. Our results will help elucidating the sequence determinants of substrate recognition for degradation of chloroplastic proteins.

Fusarium graminearum is the main fungal pathogen associated with Fusarium head blight (FHB). The trichothecene (TCH) deoxynivalenol (DON) is one of the major mycotoxins produced contaminating agricultural products. Trichodiene synthase catalyze the synthesis of trichodiene (TRI) intermediate in the biosynthesis of TCHs, coded by the *TRI5* gene. During trichothecene metabolism several volatile organic compounds (VOC), including TRI, are produced. Our aims were to obtain a non TCH-producing strain of *F. graminearum,* and to test the effect of synthetic analogues of plant-derived chemicals on the production of TRI by *F. graminearum*. TCH non-producing mutants were obtained using a split marker recombination approach; *TRI5* was replaced with a marker gene (*hph*, which confers resistance to hygromicin B). Seventeen transformants were obtained, 76% of them were -*TRI5* mutants confirmed by PCR, qRT-PCR, aggressiveness tests (F = 23.28) and inability to produce DON. Volatiles were analyzed by head space-solid phase microextraction (HS-SPME) coupled to capillary gas cromatography-mass spectrometry (CGC-MS). This technique is useful for early detection of *F. graminearum* before FHB development. In -*TRI5* mutants no sesquiterpene volatile compounds were detected. Wheat cultivars were inoculated with TRI synthase inhibitors in field assays, one of the -*TRI5* mutants was used as control. Of the chemicals tested, apocynin and eugenol produced a significant inhibition of TRI amounts 2 days post inoculation (dpi). However, TRI production was recovered at later stages (> 7dpi) due to continue fungal growth. Further experiments are necessary to determine the appropriate inhibitor concentrations and/or inoculation period to prevent TCH formation throughout the critical period (15 days) of FHB development. These studies are of interest in FHB control.

(1535) **CHARACTERIZATION OF CASEINOLYTIC ACTIVITY OF TWO *S. tuberosum* ASPARTIC PROTEASES (*St*APs)**

Florencia Rocio Tito, Alfonso Pepe, Claudia Virginia Tonón, Gustavo Raul Daleo, Maria Gabriela Guevara
Instituto de Investigaciones Biologicas (IIB), Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Universidad Nacional de Mar del Plata.

Worldwide increasing cheese demand has led to the search of novel proteases with milk clotting activity. Plants are used as source of proteases due to their easy availability, efficient purification processes and isolation of natural coagulant.

*St*AP1 and *St*AP3 are two aspartic proteases (APs) from potato tubers and leaves with milk-clotting and caseinolytic activity. The aim of this work was to optimize the caseinolytic activity of *St*AP1 y *St*AP3 and to test the specific activity on bovine casein subunits.

Box-Behnken design with three factors at three different levels was used to optimize the caseinolytic activity. Second order models were used to generate response surface contours (RSC). Optimum condition determined for caseinolytic activity were: pH 8,20, temperature 43,19ºC and concentration $5{,}20 \times 10^{-7}$ M for StAP1, and pH 8,21, temperature 42,68ºC and concentration $5{,}16 \times 10^{-7}$ M for StAP3. These conditions are compatible with ones required for industrial cheese making process.

Additionally, we evaluated the specific activity of *St*AP1 and *St*AP3 on casein subunits (α, β and κ). In order to do that, we incubate each *St*AP with casein subunits for 2 h and the degradation patterns were analyzed by SDS-PAGE. Densitometric analysis were performed using Scion Image. Results obtained shown that β-casein was degraded by both APs in a major proportion than others casein subunits (34% for StAP1 and 66% for StAP3). The percentages of degradation to α-casein were 25% and 36%, to *St*AP1 and *St*AP3, respectively. Finally, κ-casein was degraded 18% for *St*AP1 and 23% for *St*AP3. These results suggest that *St*AP1 y *St*AP3 degrade mainly β-casein. However, the minor degradation of κ-casein is enough to inducing milk clotting. Based on this results *St*AP1 y *St*AP3 might be considered a promising alternative of natural calf rennet for the coagulation of milk leading to new dairy products.

Keywords: proteolytic enzymes, milk-clotting activity, plant proteases, cheese making.

(1541) **CHARACTERIZATION OF THE ALTERNATIVE SPLICING VARIANT OF THE PIP SUBFAMILY IN *Medicago Truncatula:* THE TRUNCATED PROTEINS VARIANTS AS NEW ELEMENTS OF HETERO-OLIGOMERIZATION REGULATION**

Victoria Andrea Vitali (1), Cintia Jozefkowicz (2), Romina Frare (2), Ezequiel Petrillo (3), Gerd Patrick Bienert (4), Gabriela Soto (2), Karina Alleva (5)

Paladini" IQUIFIB UBA-CONICET.

PIPs are transmembrane proteins of great biological importance given the large number of representatives found in plants and the specific ability to transport different small compounds (water, CO_2, H_2O_2, ions). The functional diversity and localization of this protein family is usually attributed to three possible mechanisms: a) transcriptional regulation and mRNA processing; B) interaction of different monomers forming hetero-oligomers and c) the presence of regulatory subunits coupled to the structure of the transmembrane proteins. To date, in this family, important advances have been made in understanding the post-translational regulation mechanisms such as hetero-oligomerization and gating by pH, calcium, and / or phos-

phorylation. In contrast, the mechanisms of transcriptional regulation and RNA processing have not yet been addressed in depth. In the field of biology, co-transcriptional modifications occurring on mRNAs by splicing and alternative splicing are crucial in the protein diversity present in eukaryotic organisms. Our preliminary results in *Medicago truncatula* suggest that splicing variants would determine the translation of truncated protein variants. Unlike prior reports for other plant Membrane Intrinsic Proteins (MIPs), these protein variants lack two transmembrane helix and one extracellular loop. The existence of these variants open new questions about the role they could play in PIP regulation in particular but in plant metabolism in general.

(1551) **CLPB3 FROM *ARABIDOPSIS THALIANA* DISPLAYS CHAPERONE ACTIVITY *PER SE***

Ivana L. Parcerisa, German L. Rosano, Eduardo A. Ceccarelli
Instituto de Biología Molecular y Celular de Rosario (IBR-CONICET-UNR)

Abstract: All cells have developed a protein network involved in maintaining the proteome homeostasis, particularly after periods of stress. When massive protein aggregation occurs due to heat exposure, cell survival relies on the ClpB/Hsp100 subfamily of molecular chaperones which promote the solubilization and reactivation of protein aggregates. The bacterial chaperone ClpB and its homologue in yeast, Hsp104 are the most extensively studied disaggregases. Like many members of the AAA+ superfamily, ClpB/Hsp104 protomers form ring-like homohexameric complexes.The mechanical energy necessary to disentangle protein aggregates is provided by ATP hydrolysis at the two nucleotide-binding domains of each monomer. ClpB and Hsp104 collaborate with the DnaK or Hsp70 chaperone system, respectively, to dissolve protein aggregates both *in vivo* and *in vitro*, with DnaK/Hsp70 playing a main function in the regulation of ClpB/Hsp104 activity. In the present study, we have explored the substrate recognition by ClpB from *A. thaliana* chloroplasts (*At*ClpB3) and the role of its cpHsp70 chaperones in this recognition. We demonstrated that *At*ClpB3 ATPase activity is stimulated by caseins, poly-lysine and glucose-6-phosphate dehydrogenase (G6PDH) aggregates, but not by luciferase aggregates. In addition, cpHsp70s did not enhance *At*ClpB3 activity, albeit the presence of caseins. Likewise, *At*ClpB3 could mediate G6PDH disaggregation independently from cpHsp70 chaperones, recovering the activity of the denatured enzyme up to a 65 %. Besides, it has distinct properties not previously reported for Hsp104 or ClpB, as it interacts more efficiently with the aggregated G6PDH in the presence of the non-hydrolysable ATP analog AMP-PNP rather than ATPγS. This is the first evidence that a ClpB disaggregating activity can be exerted without the participation of other proteins and establishes a first approach to understanding *At*ClpB3 substrate preferences.
Keywords: ClpB, Hsp100 chaperone, disaggregases, Hsp70, *Arabidopsis thaliana*

(1673) **THREE NEW CYSTEINE PEPTIDASES CLONED AND SEQUENCED FROM FRUITS OF *Bromelia hieronymi* MEZ (BROMELIACEAE)**

María Laura Colombo, Constanza Liggieri, Agustina Fernández, Sandra Vairo Cavalli, Mariela Bruno
CIPROVE, Facultad de Ciencias Exactas, UNLP. Centro asociado a CICpBA

Fruits of *Bromelia hieronymi* Mez (Bromeliaceae) contain high amounts of cysteine peptidases (CPs), which have been characterized from the biochemical and kinetic point of view. These peptidases are capable to hydrolyze food proteins, releasing bioactive peptides with both antioxidant and antihypertensive activities. The aim of the present work included cloning and sequencing of several CPs from RNA obtained from unripe fruits. The total RNA was extracted from 0.2 g of fruit crushed with liquid nitrogen. Retrotranscription reaction was carried out to synthesize the cDNA. Then, a specific primer designed from conserved N-terminal sequences of CPs was used in a PCR in order to amplify and select peptidase cDNAs. The amplified products about of 990 bp were cloned into pGEM-T Easy vector and transformed into competent Top 10 *Escherichia coli* cells. Ten clones were selected, and sequences corresponding to three new peptidases were obtained and named Bh-CP 3, 4, and 5. Their deduced amino-acid sequences encoded three proteins of 230 residues each one, with molecular masses of 24781.82, 24787.92, and 24793.88 kDa, respectively. The predicted pI was a unique value (8.41), and the aliphatic index presented values of 71.65, 74.22, and 73.35, respectively. All sequences displayed the characteristic primary structure of plant CPs (including four residues of the catalytic site, and six Cys residues involved in disulfide bonds), and did not present possible N-glycosylation sites. Bh-cp 3, 4, and 5 showed 97, 99, and 97% of identity with Bh-CP1, other peptidase sequenced from *B. hieronymi*, and all of them showed 87 % identity with fruit bromelain from *Ananas comosus*. This work is the first step to express these enzymes, which might be promising biocatalysts for food and pharmaceutical industries.
Keywords: Bromelia hieronymi, cysteine peptidase, cloning, sequencing

(155) **RECOMBINANT PRODUCTION OF THE ARABIDOPSIS MITOCHONDRIAL ENZYMES PROLINE DEHYDROGENASE AND P5C DEHYDROGENASE**

Fabro Georgina, Germán Deza-Borau, Maria Elena Alvarez
CIQUIBIC, DQB-FCQ, UNC.

The aim of our work is to determine the activity and oligomeric state of the Arabidopsis enzymes proline (Pro) dehydrogenase (ProDH) and P5C dehydrogenase (P5CDH) that participate from Pro catabolism in the matrix of plant mitochondria. We also need to evaluate if there is physical interaction between these proteins and, if so, the protein domains involved. To address the above-mentioned issues *in vitro* we expressed the proteins as recombinants in *E. coli*. Arabidopsis cDNA was used as template and adequate primers designed to clone the full length open reading frame of the genes *ProDH1*, *ProDH2* y *P5CDH* without the mitochondrial transit peptide, as well as mutant versions of ProDHs lacking the N-terminal or P5CDH without the C- terminal into the pMAL-p2p vector. This expression plasmid allows N-terminal fusions to the Maltose Binding Protein (MBP), which, as we confirmed, increases the fraction of soluble fusion proteins obtained. It also contains a cleavage site for the Prescission protease to detach the protein of interest from the tag. We used *E. coli* BL21DE to test different conditions to optimize the soluble expression of the proteins (temperature, time and inducer concentration –IPTG-). Soluble fusion proteins were purified by affinity chromatography with amylose resin and we could verify that either tagged or untagged these were properly recognized by homemade polyclonal antibodies developed in the laboratory against peptides of ProDH and P5CDH. The activity of ProDH1 and ProDH2 were determined by using spectrophotometry monitoring the reduction of the absorbance at 600nm of the acceptor DCPIP. Details about experiments designed to evaluate oligomerization state and interaction will be presented.
Keywords: ProDH, P5CDH, Proline, Arabidopsis, Recombinant proteins.

(441) **ROLE OF GLUCOCORTICOIDS IN MYELOID LEUKEMIA CELL DIFFERENTIATION INDUCED BY RETINOIC ACID**

Micaela Silbermins (1), Adali Pecci (1, 2), Luciana Rocha Viegas (1)
(1) IFIBYNE-UBA-CONICET. (2) Dpto. Química Biológica, FCEN-UBA.

The leukemias are malignant diseases of hematopoietic cells in which the proper balance between proliferation, differentiation and apoptosis is no longer operative. Synthetic glucocorticoids like dexametasone (Dex) are frequently used in the treatment of hematopoietic diseases due to its pro-apoptotic properties. On the other hand, in many clinical trials the differentiation inducer retinoic acid (RA) resulted not encouraging in most myeloid patients. In this sense, our hypothesis suggests that a combination of steroid hormones and RA

could represent an alternative and promising therapy. The main goal of this project is to study the role of glucocorticoids in RA-induced human promyelocytic leukemia cell differentiation. Undifferentiated NB4 cells were treated with RA in the presence or absence of Dex over 72h. Our results showed that Dex markedly enhances a RA-induced cell differentiation response, observed as a potentiated expression of the cell surface marker CD11c by flow cytometry analysis (control: (0±1)% RA: (19±2)% RA+Dex: (54±3)% - p≤0.01). To gain functional insights into this differentiation process, the expression of *hox* genes, *pscd4*, *meis2, gr* and *rarβ* was monitored in RT-qPCR assays. Notably, upon 48h, the addition of Dex potentiates RA-induced expression of *hoxA3* (p≤0.02) and *pscd4* (p≤0.05) genes. Finally, PML-RARα and RARα protein down-regulation upon RA stimulation was confirmed by western blot, and remained unchanged upon combined treatment with Dex. Overall, our data reveals the existence of a synergistic effect of Dex and RA on NB4 cell differentiation. Further characterization of this molecular context could aid to identify attractive targets for therapeutic strategies in myeloid leukemia.

Dileyvic Giambalvo (1), Gabriel Fiszman (2), Gabriela Lombardi (1), Maria Elena Sales (1)

(1) Laboratorio de Inmunofarmacología Tumoral CEFyBO UBA CONICET. (2) Departamento de Inmunología, Instituto de Oncología Angel H Roffo.

Abstract: Systemic humoral response against different antigens in tumor bearers has been reported. We documented that immunoglobulin G (IgG) from breast cancer (BC) patients in T1N0Mx (tumor size<2 cm, without lymph node metastasis) promotes tumor progression by activation of cholinergic receptors express in tumor cells. We also reported that non-neuronal cholinergic system is present in human dendritic cells (DC), and T1N0Mx-IgG modulates the expression of maturation markers and the production of cytokines by these cells, reinforcing the tolerogenic/immunosuppressive profile in these patients. Here, we analyzed the effect of T1N0Mx-IgG on vascular endothelial growth factor-A (VEGF-A) and matrix metalloproteinase-9 (MMP-9) production by DC as promoters of tumor progression. DC were obtained from human monocytes cultured with IL-4 and GM-CSF for 5 days. Then, cells were cultured with or without LPS to obtain mature DC (mDC) or inmature (iDC). By Western blot, we demonstrated that iDC and mDC express VEGF-A. The addition of T1N0Mx-IgG (10^{-8}M) for 1 h increased VEGF-A expression only in mDC (2.19±0.38; p≤0.01 vs. control). The preincubation of mDC with cholinergic antagonists reduced this effect. Moreover, we found that both iDC and mDC express the pro-MMP9 and MMP-9 active forms (by zimography), and T1N0Mx-IgG increased MMP-9 activity in both cell populations (iDC:1.67±0.01; p≤0,01; vs. control iDC; mDC:1.77±0.44; p≤0,001 vs. control mDC). This effect was also reduced by the preincubation of cells with cholinergic antagonists. In conclusion, the interaction between DC and T1N0Mx-IgG through cholinergic receptors up-regulated VEGF-A and MMP-9 production by DC; these mediators could not only promote tumor progression but also the immunosuppressive profile of patients with BC.

Keywords: autoantibodies, breast cancer, dendritic cells, cholinergic system.

(507) **BEXAROTENE TREATMENT FOR CUTANEOUS T CELL LYMPHOMA (CTCL): IMPLICATIONS OF THYROID HORMONE (TH) REPLACEMENT IN THE ANTI-LYMPHOMA ACTIVITY AND IN THE ANTITUMORAL IMMUNE RESPONSE.**

Maria Florencia Cayrol (1), Maria Mercedes Debernardi (1), Maria Victoria Revuelta (2), Alejandra Paulazo (1), Maria Nieves Calvo Vidal (2), Jude Philip (2), Helena Sterle (1), Maria Celeste Diaz Flaque (1), Leandro Cerchietti (2), Graciela Cremaschi (1)

Instituto de investigaciones biomédicas-UCA-CONICET. (2) Department of Medicine, Hematology and Oncology Division, Weill Cornell Medicine.

Bexarotene (Bex) is used for the treatment of CTCL and is associated with hypothyroidism, so patients concomitantly received TH administration. We found that physiological levels of TH increase the proliferation of CTCL by activating TH membrane receptor, integrin αVβ3 (mTR). Here, we determined the influence of TH replacement therapy on the anti-lymphoma activity of Bex.

In standard conditions, Bex decreases the proliferation and viability of HuT78 and MJ CTCL cells. To study this mechanism we conducted RNA-sequencing in Bex-treated HuT78 cells (vs. vehicle) and found that Bex up-regulates genes related to *cell proliferation and differentiation* (*REL, CCND1*) and to *immunity* (*TBX21, IFNG*). This suggests that Bex treatment could impact in antitumor immunity. In TH-depleted culture conditions we observed a higher effect of Bex on CTCL viability. As hypothyroidism is associated with marked immunosuppression, thus favouring CTCL progression, we determined the impact of TH replacement on Bex using a murine TCL model of EL4 cells. Once tumors developed, we treated mice with vehicle (Veh), Bex (Bex) and Bex with TH replacement (BexT4+). Bex administration decreased tumor growth being the effect significantly higher in the absence of T4 replacement (p<0.05 vs Bex). Mice with Bex showed a significant decrease of $CD8^+CD44^+$ T-cells (p<0.05 vs. BexT4+) and an increase of myeloid-derived suppressor cells in lymph nodes, indicating that Bex should be administered with T4 to avoid a negative immune microenvironment.

Then, we analyzed if the inhibition of the mTR would impair the pro-survival effect of TH. TCL tumor-bearing mice were treated with Veh or BexT4+ in combination (BexT4+Cil) or not with cilengitide 40mg/kg. Atthe end of treatment, BexT4+Cil mice showed significantly smaller tumors than Veh and BexT4+ mice (p<0.001 and p<0.05, respectively). Our data indicates that the inhibition of the integrin αVβ3 could be an effective strategy to improve Bex-based treatments in CTCL.

(1785) **BREAST CANCER SHAPES THE B CELL COMPARTMENT TOWARDS IMMATURE DEVELOPMENTAL STAGES**

Nicolás Sarbia, Verónica C. Martínez Allo, Montana N. Manselle Cocco, Sabrina Gatto, Rosa M. Morales, Tomás D´Alotto-Moreno, Gabriel A. Rabinovich, Mariana Salatino, Marta A. Toscano

Laboratorio de Inmunopatología, Instituto de Biología y Medicina Experimental, CONICET.

Unlike T cells, that have been broadly studied in anti-tumor immunity, the role of B cells in cancer progression remains a matter of controversy. Using different murine tumor models (4T1, LM3 and CT26) we sought to understand how the B cell compartment is phenotypically and functionally shaped by the presence of tumors, altering the host's immune response. For this, we analyzed B cell ontogeny by determining the frequency and number of B cell subsets in the bone marrow and spleen of tumor-free and tumor-bearing mice. We found that mice with 4T1 and LM3 mammary tumors had a dramatic reduction in the number of bone marrow B cells B220+ CD19+ (p<0.05), when compared to BALB/c mice without tumor. In addition, we found an altered frequency of the different subsets of B cells in the bone marrow, including decreased mature recirculating B cells (p<0.001) and increased pre- and pro- B cells (p<0.05). Changes in B cell development were also observed in the following steps of B cell maturation, with an increased frequency of splenic transitional 1 B cells in mice with 4T1 tumor compared to tumor-free controls (p<0.001). Transitional 2 (p<0.05), follicular (p<0.001) and marginal zone B cells (p<0.0001) were fewer in frequency in the presence of 4T1 tumor. In line with this evidence, we also found an elevated proportion of immature CD93+ B cells inside 4T1 tumors. On the contrary, the presence of a CT26 colon tumor did not alter the B cell compartment suggesting that the observed effect was a feature of breast tumors. As immature B cells display immune suppressive activity it is likely that, once these cells are recruited to the tumor, they

modulate anti-tumor immunity favoring tumor progression. Further studies on the mechanism underlying tumor-driven modulation of the B cell compartment will unveil novel targets for cancer immunotherapy.

Keywords: B cell compartment, breast cancer, immature B cells, anti-tumor immunity.

(1735) **CHARACTERIZATION OF THE NEWLY DEVELOPED TLR3-GFP MICE: NOVEL REPORTER TOOL FOR STUDYING THE EXPRESSION OF TLR3**

Emiliano Roselli (1), Paula Araya (1), Nicolas Gonzalo Nuñez (2), Francesca Graziano (3), Philippe Benaroch (3), Eliane Piaggio (3), Mariana Maccioni (1)
(1) CIBICI-Dpto.Bioquimica Clinica-FCQ-UNC. (2) University of Zurich - Institute of Experimental Immunology. (3) (Institut Curie - U932 Laboratoire d'immunologie.

TLR3, an endosomal receptor, is able to recognize dsRNA present in the abnormal location of the endocytic pathway. For some year now, the lack of a properly working antibody against TLR3 has been a methodological barrier for a more profound study of the receptor. Our collaborators at Institut Curie have developed a TLR3-GFP knock-in mice where the gene for GFP was introduced downstream the TLR3 promoter in order to generate a fusion protein to properly follow TLR3. In this work, we first characterized the expression of TLR3 on different cell subsets purified from harvested organs of TLR3-GFP mice (spleen, ingLNs, mesenteric LNs, bone marrow, lung, gut), and as expected from data banks we detected expression of TLR3 on different subsets of dendritic cells present in these organs, CD8α+ DCs being the main one. To note, the proportion of TLR3+ cells varied from organ to organ detecting TLR3 expression in CD8α+DCs and a subpopulation of B cells in the spleen. We then took one group of reporter mice receiving i.p. injections of 200μg of poly I:C (pIC), a well-known TLR3 agonist, and a control group receiving vehicle; and evaluated the activation state of these TLR3+ populations 24h post-injection. When we analysed CD86 and MHCII we did not observe any significant changes on TLR3-GFP mice treated and non-treated with pIC while we did observe activation upon pIC on littermate controls. This suggested an incomplete capacity of TLR3 to respond to its ligand on the reporter mice. To further characterise these mice we took an *in vitro* approach and obtained BMDMs (Bone Marrow-Derived Macrophages) from TLR3-GFP and littermate controls and stimulated them with pIC and poly A:U, both well-established TLR3 agonists, and after 24h we evaluated activation markers, observing that littermate controls responded by upregulating activation markers while TLR3-GFP failed to do so. These results suggest that TLR3-GFP mice are a useful tool to follow TLR3 but fail to respond to its stimuli.

(1051) **CHRONIC LYMPHOCYTIC LEUKEMIA: ANTI-CD20 THERAPEUTIC ANTIBODIES AND BCR KINASE INHIBITORS OVERCOME LEUKEMIC CELL RESISTANCE TO VENETOCLAX (ABT-199)**

Esteban Enrique Elías (1), Maria Belén Almejun (1), Mercedes Borge (1), Ana Colado (1), Enrique Podaza (1), Denise Risnik (1), Horacio Fernandez Grecco (2), Manuela Clavijo (3), Claudia Casali (3), Gonzalo Garate (3), Raymundo Fernando Bezares (4), Mirta Giordano (1), Romina Gamberale (1)
(1) IMEX-CONICET-ANM, (2) Sanatorio Dr. Julio Mendez, (3) Hospital Alemán, (4) Hospital General de Agudos Dr. Teodoro Alvarez

Leukemic B cells from CLL patients survive and proliferate within lymphoid tissues in contact with activated T cells and myeloid cells and receiving signals through the BCR. Effective therapy should target both, leukemic cells from peripheral blood and from the protective microenvironment. We previously reported that ABT-199, a potent BCL2 inhibitor, is highly cytotoxic against unstimulated CLL cells but it is much less effective against CLL cells that received survival signals from activated T cells, suggesting that leukemic cells from the supportive microenvironment might not be properly targeted by the drug. The aim of this study was to overcome the ABT-199 resistance using combined therapies with anti-CD20 MoAbs and/or BCR-associated kinase inhibitors (BCR-KI). To this aim peripheral blood mononuclear cells from CLL patients were cultured with anti-CD3 (aCD3) to activate autologous T cells with or without ABT-199 and the BCR-KI GS-9973. CLL cell survival was evaluated by flow cytometry; the expression of BCL2 family proteins by western blot and phagocytosis of CFSE-labeled CLL cells coated with anti-CD20, Rituximab (Rx) by flow cytometry and confocal microscopy. We confirmed that autologous T cell activation induced ABT-199 resistance on CLL cells (n=18, $p<0.01$) which was associated with the upregulation of MCL1 and BCL-XL on the leukemic clone (n=6). GS-9973, which impairs T cell activation (Colado A, Cancer Immunol Immunother. 2016), overcame aCD3-mediated resistance of CLL cells to ABT-199 (n=14, $p<0.05$). Finally, we found that ABT-199 allowed a more successful phagocytosis of Rx-coated CLL cells (n=18, $p<0.05$).

Our results encourage the combination of ABT-199 with BCR kinase inhibitors, such as GS-9973 which overcame the resistance induced by activated T cells. Combination with CD20 MoAbs could also be useful because ABT-199-enhanced the phagocytosis of Rx-coated-CLL cells.

Key words: CLL, ABT-199, microenvironment, GS-9973, rituximab.

(414) **CHRONIC PROSTATE INFLAMMATION INDUCED BY *E. coli* INFECTION LEADS TO TISSUE LESIONS ASSOCIATED TO PROSTATE CANCER DEVELOPMENT**

Florencia C. Salazar, Gloria J. Godoy, Carolina Olivera, Virginia E. Rivero, Rubén D. Motrich
CIBICI-CONICET. FCQ-UNC

Prostate cancer (CaP) is the second most frequent type of cancer in men. Prostate carcinogenesis is multifactorial and several environmental and genetic factors are involved. In this set, chronic inflammation was suggested as an important risk factor by several epidemiological studies. Herein, and using an animal model, we analyzed if chronic prostate inflammation caused by *Escherichia coli* infection may have a role in prostate carcinogenesis.

Male C57BL/6 mice were transurethrally inoculated with $2x10^8$ CFU of uropathogenic *E. coli* 1677 (infected) or saline (controls), euthanized at 5 days (dpi), 12 and 26 weeks (wpi) post infection, and the immune response, prostate infiltrating leukocytes and histopathology analyzed.

Inoculated animals developed an ascending infection early after infection (5 dpi) that persisted along time (12 and 26 wpi). Infection induced inflammation that was characterized by significantly increased circulating IL17+ and IFNg+ T cells when compared with controls ($p<0,05$), either at early (5 dpi) or late times after inoculation (12 and 26 wpi). The peripheral immune response was accompanied by histological lesions in the prostate from infected mice. Several acute inflammation foci, mainly composed of Gr1+ cell infiltrates, hemorrhage, necrotic debris, abundant epithelial shedding and tissue disorganization were shown at 5 dpi. Later on, prominent chronic inflammation was evident by dense infiltrates in the stroma, mostly composed of CD3+ and CD11c+ cells (12 and 26 dpi). Strikingly, sites of intense inflammation were associated with shedding of epithelial cells, papillomatosis, and varying degrees of atypical hyperplasia and dysplastic changes mimicking high grade prostate intraepithelial neoplasia.

Our results indicate that chronic bacterial infection of the prostate induces chronic inflammation associated in close proximity with tissue changes similar to neoplastic lesions, which could constitute a potential precursor of prostate adenocarcinoma.

The role of IL-17 cytokines in cancer remains controversial as anti- and pro-tumoral effects have been described. We and others demonstrated that IL-17 family plays a central role for the induction of NK and CD8+ T cell (CTL) responses. As these subsets are critical for cancer resistance, we evaluated the role of IL-17/IL-17R in modulating anti-tumor immunity and tumor progression. To this end, B6 (WT), IL-17RA KO (RKO) and IL-17A/F double KO (DKO) mice were injected with tumor cell lines exhibiting progressor (B16-SIY and MCA101-OVA) and regressor (MC57-SIY) growth patterns. Previously, we showed that volumes of B16 and MC57, but not MCA101, tumors were increased in RKO and DKO mice compared to WT mice at several days post injection (dpi). Analysis of the primary immune response against MC57 demonstrated that compared to WT controls, DKO mice presented reduced numbers of SIY-specific CTL in draining-lymph nodes at d12pi ($p<0.05$). Also, tumor-specific CTL displayed decreased frequency of cells with memory phenotype (CD62L+CD127+). As the memory CTL response developed in MC57-SIY-immunized WT mice is critical to host protection against challenge with B16-SIY tumors, we aimed at evaluating whether RKO and DKO mice were also able to generate protective SIY-specific CTL. Then, we challenged MC57-SIY immunized mice with B16-SIY tumor cells and determined tumor growth until day 32 post challenge (pc). While most (75%) of immunized WT mice rejected B16 tumor, DKO and RKO mice were less protected as only few mice (around 20%) were tumor free at d32pc ($p<0.05$). Accordingly, blood and tumors of DKO mice showed reduced frequency of SIY-specific CTL ($p<0.05$) as well as decreased tumor-specific cells with a memory effector phenotype ($CD44^+CD62L^-$; $p<0.001$) in comparison to WT controls at day 8pc. Altogether, our results suggest that the IL-17/IL-17RA pathway modulates primary and secondary antitumor CTL responses and may influence tumor progression in certain cancers.

Immunotherapy has been gaining importance in cancer treatment. In particular, some vaccination strategies focus on the presence of carbohydrate structures associated with tumor cells. Aberrant glycosylation is a phenomenon described in the malignant transformation and includes loss or excessive expression of certain glycans and appearance of unfinished and novel structures. The ganglioside GD2 is a tumor-associated glycan, highly expressed on cancer cells of neuroectodermal origin, including neuroblastoma, melanoma, brain tumors and small cell lung cancer. Taking into account that carbohydrates are T-cell-independent antigens and thus generate poor immune responses; the aim of this work was to develop a peptide compound that mimicsGD2, for its future use as the active compound in a cancer vaccine. We have selected a series of peptide candidates that mimic the structure of GD2, using the Ph.D.12 Phage Display Peptide Library Kit (NEB) and a monoclonal antibody (Ab) specific for human GD2 (clone 14G2a, Biolegend) as screening Ab. Four candidates were selected after a sequence alignment and taking into account their hydrophilicity. Candidates were able to bind to the screening Ab in an ELISA assay. Moreover, when pre-incubated with the screening Ab, they were able to interfere in its binding to GD2-positive tumor cells in a flow cytometry assay. Based on these results and their antigenic mimetic capacity, we selected the most promising candidate and fused its sequence with the bacterial carrier BLS (Brucella lumazine synthase). This highly immunogenic platform allows the production of chimeric proteins decorated with ten copies of the desired peptide. The anti-GD2 Ab was able to recognize the resulting chimera in a Western Blot. Our results demonstrate the experimental approach used is appropriate for selecting peptides with glycan antigen-mimicry and the promise of becoming potential active compounds in an immunotherapy against GD2-expressing tumors.

The identification of effective new therapies for prostate cancer requires a better understanding of the multiple molecular interactions between tumor cells and their associated stroma. In this context, Galectin-1 (Gal-1) plays a major role determining the properties of the prostatic carcinoma microenvironment. The aim of this study was to elucidate whether Gal-1, in addition to promote tumor neoangiogenesis and immune regulations, plays an additional role as an intrinsic regulator of $CD8^+$ T cell function.

To address this, we used two approaches: an *in vitro* T cell polyclonal activation model, combining different cell types (purified by cell sorting) in a prostate tumor microenvironment and an adoptive transfer of Gal-1 deficient *Lgals1*$^{-/-}$ (KO) and wild type (WT) cells into immunodeficient mice.

The *in vitro* combination of KO and WT cells, allowed us to elucidate how the endogenous Gal-1 of each cellular compartment impacts on the $CD8^+$ T cell proliferation and citotoxicity. The absence of Gal-1 in antigen presenting cells did not significantly modify any function of $CD8^+$T cells. Conversely, the absence of Gal-1 in $CD4^+$ T cells induced a 1.21 fold increase in the proliferation of CD8+T cells. However, the most significant difference in the proliferation was obtained by absence of intrinsic Gal-1 in the $CD8^+$ T cells themselves (2.12). We further evaluated whether Gal-1 is relevant for effector function. Our results demonstrated that upon activation, KO T cells have increased their ability to degranulate (evaluated as % (1.87 fold) and the content of granules (2.48 fold increase) ($p<0.05$, t test Student).

We then compared the *in vivo* tumor growth in nude mice adoptively reconstituted with Gal1 KO or WT immune systems: the presence of KO immune cells increased for 24.1 days the lag time and doubled the tumor duplication time. These results demonstrate that Gal-1 modulates the intrinsic function of lymphocytes in a prostate cancer context.

(4) Servicio de Anatomía Patológica, Hospital Italiano de Buenos Aires. (5) (Instituto de Ciências Básicas da Saúde, Universidade Federal do Rio Grande do Sul.

Melanoma is an aggressive cancer with highly metastatic ability. We propose cofilin-1, a key protein in the regulation of actin dy-

namics and migration, as a prognostic marker. We determined cofilin-1 levels in a retrospective cohort of patients with melanomas and benign lesions of melanocytes (nevi) by immunohistochemistry. Results show a significant association between high levels of cofilin-1 and tumor malignant features, such as advanced stages of malignant melanoma (MM) ($p<0.001$), increased number of mitosis per field ($p<0.05$) and Breslow index (BI) ($p<0.05$). Higher cofilin-1 levels were found in MM with BI>2 vs MM with BI<2 ($p<0.05$) and vs melanoma in situ (MIS) and nevi ($p<0.001$). MM with metastasis also showed increased cofilin-1 levels vs MM without detected metastasis ($p<0.01$). Kaplan-Maier survival curves were performed, clustering patients according either to the type of melanocytic lesions (nevus, MIS, MM BI<2 and MM BI>2) and to the cofilin-1 level. Significant differences among the different types of lesions were found ($p<0.05$) and those patients with higher cofilin-1 levels exhibited lower survival rate at 5 years ($p<0.0001$). Moreover, a significant negative correlation between survival percentage and cofilin-1 levels (Spearman's Rho: R=-0.73, p=0) was found. Therefore, the levels of cofilin-1 can be associated with melanoma outcome in this patient cohort. Supporting these results, TCGA database analysis of a melanoma cohort also showed low survival in patients with upregulated cofilin-1 mRNA. As cofilin-1 has a dual function depending on its intracellular localization, we evaluated nuclear and cytoplasmic levels of cofilin-1 by immunofluorescence. An increase in nuclear/cytoplasmic cofilin-1 mean fluorescence ratio was observed in MM with BI>2 vs MM with BI<2, MIS and nevi. In conclusion, our study suggests that not only the higher levels of cofilin-1, but also its nuclear localization can be markers of worse outcome of patients with melanoma.

Introduction: Locally Advanced Rectal Cancer (LARC) response to preoperative chemoradiotherapy (CRT) is very heterogeneous. Current prognosis-related factors lack robustness to individualize therapeutic decisions. Four Consensus Molecular Subtypes (CMS) represent the current best description of colorectal cancer heterogeneity at the gene expression level. We aim to integrate CMS predictions with available clinical data from an Argentinian LARC cohort in search of biomarkers to improve patient management. **Methods:** We analyzed gene expression in baseline tumor biopsies of the first 24 LARC patients from an ongoing recruiting translational research trial. Mutations in RAS and BRAF were measured by PCR Entrogen panel. DNA repair proteins(MLH1,MSH2,MSH6,PMS2) were measured by Cell Marque monoclonal primary antibodies. Gene expression data was obtained using Agilent Agi4x44K Whole Human Genome microarrays, and CMS-classified with the R package 'CMSclassifier' using a similarity-to-centroid approach. **Results:** Subtype classification showed CMS2-Canonical subtype patients (79%) of which one showed MSH2 gene and protein expression deficit, and one carried KRAS G12A mutation; CMS3-Metabolic (13%) with one KRAS-mut patient; CMS1-MSI immune (4%) diagnosed Lynch Syndrome confirmed by a germinal MSH2 mutation; CMS4-Mesenchymal (4%) showing higher stromal gene expression. **Conclusion:** To our knowledge, this is the first classification of local LARC patients into descripted colorectal molecular subtypes combining prospective clinical and genomic data to enrich patient characterization. We expect that future analyzed cases from this ongoing trial might help us establish further molecular features to correlate with CRT response.

Abstract: Radioresistance is defined as a cell's capacity to survive after exposure to high energy radiation, a fact that may limit therapeutic options by reducing the efficacy of radiotherapy (Rt). Numerous tumor cells show a high expression of cyclooxygenase-2 (COX-2), a fact that has been linked to more aggresive tumor phenotypes. Also, the COX-2 inhibitor celecoxib (CXB) has been proposed as a possible Rt enhancer. We aim here to investigate whether COX-2 activity and expression regulate radiosensibility in a radioresistant lung adenocarcinoma-derived cell line (A549). Cells were exposed to varying doses (0-10 Gy) of ^{60}Co ionizing radiation (IR) in the presence or the absence of 7.5 mM CXB and radiosensitivity was determined using a standard clonogenic assay, cell cycle was studied by flow cytometry after propidium iodide staining and MAPKs activation and COX-2 expression by western blot using specific antibodies.

IR produced a significant and dose-dependent reduction of cell viability showing an a/b ratio of 14.2 when calculated using the linear quadratic model, an effect that was significantly ($p<0.05$) enhanced by CXB. Rt (2.5 Gy) induced a clear G0/G1 phase accumulation and a reduction of G2/M phase when compared to control (79.0 vs 68.0 and 9.0 vs 15.5% for Rt and control, respectively), whereas CXB had no effect on cell cycle. CXB produced a significant ($p<0.05$) and rapid activation of p38 and JNK (5 and 10 min after exposure) but had no effect on COX-2 expression for up to 120 min as determined by Western blot.

Our results show that inhibition of COX-2 activity increases the effect of IR in A549 cells without affecting cell cycle progression although activating p38 and JNK. We conclude that COX-2 plays a role in the regulation of radiosensitivity of tumor cells in a mechanism that includes the participation of MAPKs.

Keywords: cyclooxygenase-2, radiosensitivity, celecoxib, p38, JNK.

(281) **DEVELOPMENT OF AN HYDROXYMETHYLGLUTHARYL-COENZYMEA REDUCTASE (HMGCR) OVEREXPRESSION SYSTEM WITH CRISPR-ON TECHNOLOGY FOR THE STUDY OF METABOLIC REPROGRAMMING TO STEM-LIKE STATES IN BREAST CANCER.**

(1) Laboratorio de Células Madre, IBYME-CONICET. (2) Unidad de Reprogramación Celular, ICBME, Instituto Universitario del Hospital Italiano de Buenos Aires.

HydroxymethylglutharyI-coenzymeA reductase is deregulated in tumors, increasing the synthesis *de novo* of cholesterol, critical for the regulation of cell survival and proliferation signals. Therefore, we aimed to induce an HMGCR-on phenotype in the breast cancer (BC)-derived cell line MCF-7, to evaluate whether this phenotype involves the acquisition of stem-like traits in BC. With this

purpose, we developed an HMGCR overexpression model taking advantage of a CRISPR-on system (dCas9-VP160), which includes expression plasmids for guide RNAs (pSPgRNAs) and a plasmid carrying the sequence coding for the CRISPR-on. Five guide RNAs (gRNAs) targeted to the promoter of the human HMGCR gene were designed with the informatics tools Genome Engineering Toolbox from the Zhang Lab (MIT, Cambridge, MA) and CRISPR-ERA. The gRNAs and the CRISPR-on were then co-transfected into MCF-7 cells, and the levels of total HMGCR and its two isoforms (FL-Full Length and DL13-deletion of exon 13) mRNAs were assessed by qRT-PCR at 2 days postransfection. The CRISPR-dCAS9 system increased HMGCR total levels in MCF-7 cells (MCF-7/HMGCR-on) by a 2,26±0,03-fold (X±SD; p<0,05) when compared to transfection controls (MCF-7/CT), due to an increase in the levels of both isoforms (FL: 2,2±0,03-fold and DL13: 1,56±0,03-fold; X±SD p<0,05). Treatment with the statin Simvastatin (SIM), decreased HMGCR levels a 0,33±0,06-fold in MCF-7/HMGCR-on cells (X±DS; p<0,05), whereas MCF-7/TC cells remained unaffected. Interestingly, changes in HMGCR levels in MCF-7/HMGCR-on and MCF-7/TC cells in the presence of SIM correlated with corresponding changes in the frequency of stem cells (R^2=1), as measured by mammosphere formation assay by limiting dilution and statistical analysis with a specialized software (http://bioinf.wehi.edu.au/software/elda). These data suggest that cellular models expressing a HMGCR-on phenotype may offer useful tools for the study of metabolic phenotypes prone to acquire stem-like traits in BC.

Glioblastoma multiforme is a type of tumor of the central nervous system (CNS), known for being one of the worst and fast-growing brain tumor. This type of cancer presents a poor prognosis after diagnosis with a survival rate of approximately one year. The current protocol for glioblastoma treatment consists in the surgical excision of the primary tumor followed by radio and chemotherapy. Photodynamic therapy (PDT) is a well-known therapeutic approach that combine two components (light and a photosensitizer (PS)) to induce cell death triggered by singlet oxygen ($^1O_2$) and/or reactive oxygen species (ROS) as a result of photochemical reactions. Phthalocyanines (Pcs), are excellent second generation photosensitizers for PDT. They present a far red wavelength absorption (>670 nm), long triplet lifetime (~1 ms), and high quantum yields of singlet oxygen generation (>0.2). In this work, we compared the capacity of ZnPc and one of its derivatives (TAZnPc) to photo inactivate glioblastoma cells *in vitro*. We analyzed the photochemical properties of both PS, their incorporation, subcellular localization and we observed a relation with the mechanism of cell death induced after illumination: ZnPc associate more to mitochondria compared to the TAZnPc which present a markedly lysosomal localization. We compared the clonogenic capacity after PDT, the type of cell death triggered, the molecular signals associated to them and the cellular organelles damaged after PDT. Also, both Pcs were vehiculizated into DPPC-cholesterol liposomes and measured the PDT capacity of both PS compared to the DMF administration. In summary, ZnPc results more efficient to photoinactivate glioblastoma cells *in vitro*, perhaps due to its subcellular localization and singlet oxygen generation, however, TAZnPc absorb in a longer wavelength allowing the irradiation with greater wavelength assuring a deep action in tissue by the PS (application in vivo).

Glioblastoma multiforme (GBM) is the most common and aggressive primary brain cancer in adults. In spite of improved standard of care (surgery, chemotherapy and radiation) the median survival of GBM patients remains dismal. Prolactin (PRL) has been recently associated to the development of several hormone-dependent cancers. However, its role in the pathogenesis of GBM remains unknown. The expression of PRL has been detected in human GBM biopsies and over 30% of brain cancer patients exhibit hyperprolactinemia, which has positive correlation with the proliferation index and the vascular density of brain tumors. We have previously observed that GBM cells secrete PRL and that the PRL receptor (RPRL) antagonist Δ1–9-G129R-hPRL reduces their proliferation rate. Now we aimed to assess the expression of RPRL in human GBM cells and the effect of PRL on the sensitivity of these cells to chemotherapeutic agents. Expression of RPRL was detected by immunofluorescence in human U251 GBM cells. Various isoforms of RPRL have been reported, which are produced by alternative splicing and differ in the length of their intracellular domain, which in turn determines the characteristics of their signaling. We assessed the expression of these isoforms by Western blot and detected abundant expression of short RPRL isoform in U251 GBM cells. We next evaluated the effect of recombinant PRL and Δ1–9-G129R-hPRL on the sensitivity of human GBM cells to chemotherapeutic drugs. We found that addition of recombinant PRL (100-500 ng/ml) reduced the cytotoxic effect of Cisplatin (5 μM) and Temozolomide (15 μM) in U251 GBM cells (p<0.05), as assessed by MTT assay. On the other hand, Δ1–9-G129R-hPRL (5 μg/ml) reduced the viability and increased the cytotoxic effect of Cisplatin in human U251 and U87 GBM cells (p<0.05). Our findings suggest that locally synthesized PRL and its receptor could constitute a therapeutic target to improve the sensitivity of GBM cells to antineoplastic agents.

The tumor microenvironment (TME) comprises multiple cellular and non-cellular components that converge to promote tumorigenesis in a variety of solid malignancies. Extracellular vesicles (EVs) have been implicated in cell-cell communication in tumor and distant microenvironments. In preliminary studies, we found that thyroid tumor cell-fibroblast interactions promoted the secretion and activation of matrix metalloproteinases (MMPs) and a migratory phenotype in tumor cells. CD147, a transmembrane glycoprotein implicated in MMPs expression, has been related to thyroid tumor progression. Our goal was to identify EVs production and their CD147 expression as mediators of malignant progression in thyroid TME. As an *in vitro* tumor-stroma cell interaction model, non-tumor cells (N-Thy-Ori), thyroid papillary carcinoma cells (TPC-1) and thyroid anaplastic cells (8505c) were co-cultured with normal fibroblasts (Fb). Cellular CD147 expression was analysed by FACS in isolated and co-cultured cells. EVs secretion and size, in cell and cell-Fb conditioned media (CMs), were characterised by Transmission Electronic Microscopy (TEM) and Dynamic Light Scattering. Isolated EVs were analysed for differential total protein expression by SDS-PAGE and Coomasie-Blue staining, and for CD147 expression by western blot-

ting and gold-immunocytochemistry. CD147 expression showed no differences in thyroid isolated and co-cultured cells while increased in co-cultured Fb, irrespective of the thyroid cell used. Isolated EVs from CMs ranged between 50-600nm. In SDS-PAGE, an extra protein band was detected in EVs from TPC-1-Fb and N-ThyOri-Fb co-cultures. CD147 expression in EVs increased in TPC-1-Fb and 8505c-Fb co-cultures, without significant changes in N-ThyOri-Fb co-cultures. The results suggest that EVs-CD147 could play an active role in intercellular communication events in thyroid TME, stimulating the release of MMPs and the consequent migration and cellular invasion.

Lung metastasis is a therapeutic challenge during osteosarcoma (OS) progression (15–30% survival rate with pulmonary metastasis at diagnosis). Niche establishment is critical for metastasis; we aimed at determining molecular and functional events that could favor a suitable OS metastatic niche. Tumor stroma plays a key role in modulating tumor progression through an interplay between tumor and stromal cells. Through proteomic run and raw data analysis we demonstrated differential gene expression related to biological processes in an OS cell line selected by enhanced lung metastatic ability (LM7). Molecular differences were reflected in different functional behavior relevant in LM7 cells as compared to non-metastatic OS cells. Interestingly, mesenchymal stem cells (MSC) cells had significance in these functional differences. We demonstrated that MSC had higher migratory response to the non-metastatic cell line SAOS2 (1.5 fold higher compared to LM7; 994.1±82.72 no. cel/field), and the metastatic cell line LM7 was more responsive to MSC' secretome (2 fold increase in migration; 752.73±83.01 no. cel/field) suggesting a prime recruitment of MSC to the primary tumor site and later a prime incorporation of metastatic cells into a niche colonized by MSC. Active metalloproteinases (MMP) were expressed only by LM7 cells. Further, MMP2 expression related with diminished metastasis free survival rate and increased overall survival pointing at a role in the creation of a functional metastatic niche (Genomics Analysis & Visualization Platform, Acad Med Center, Amsterdam). Further, proteomic analysis and qPCR validation pointed at Fas associated factors as differentially expressed proteins in metastatic OS cells probably contributing to the signaling network in the lungs niche and as a mechanism of cell selection associated to apoptosis.

(1) IFISE.

Hepatocellular carcinoma (HCC) is the second most lethal cancer, which is in part due to its rapid development of intra and extra hepatic metastasis. a-Lipoic acid (LA) is clinically used as an antioxidant. Recent studies suggest the use of LA as an anti-cancer agent, associated with activation of AMPK. However, direct evidence of LA contribution to the treatment of HCC has not been elucidated. In recent studies we have demonstrated that AMPK activation signals the survival decrease in HCC cells subjected to glucose starvation (Gs). In this study, we evaluate the effects of LA and Gs on HCC cell lines (HepG2/C3A and HuH-7) proliferation, migration and differentiation, and the putative involvement of AMPK signaling pathway. First, we demonstrated that AMPK is activated by LA, and that this activation was enhanced when the cells were incubated with Gs. LA 0.5 (LA0.5) and 1(LA1) mM decreased the number of viable cells from 48h, and this effect was enhanced in Gs (HuH-7:LA1:67±2*, LA1Gs:45±8*#; C3A:LA1: 66±5*, LA1Gs:46±3*# % vs C). Treatment with LA for a longer period of time, drastically reduced clonogenic capacity in HuH-7 cells. In addition, LA increased the percentage of these cells in G0/G1 by 20% vs C. Wound-healing assay showed that AMPK activation by 0.5mM LA reduced cell migration, and Gs increased this result (HuH-7:C:339±7*, LA0.5:191±12*, LA0.5Gs:120±15*#; C3A:C:94±4*, LA0.5:62±5*, LA0.5Gs:35±2*# μm). Cell differentiation was evaluated in C3A cells as the capacity of generating canalicular structures typical of epithelial hepatocytic cells. In fact, the number of canalicular structures significantly increased by LA. In conclusion we found that LA reduces cell proliferation and migration in HCC cells, what parallels the activation of AMPK, and these antitumor effects are increased by Gs. These findings support further studies of LA as a potential therapeutic agent for HCC treatment, alone and combined with metabolic interventions.*p<0.05 vs C, #p<0.05 vs Gs.

IBYME

Abstract: Metabolic syndrome (MeS) is a patophysiological disorder that increases prostate cancer (PCa) risk. C-Terminal Binding Protein (CtBP1), a transcriptional co-repressor of many tumor suppressor genes, is considered a molecular metabolic sensor because it needs to bind NADH to become active. Previously, in our lab we have established two mice models of MeS and PCa that allowed us to investigate CtBP1 role on tumor growth and progression from localized to metastatic disease. Both models share the same flaw; tumors were generated on immunodeficient mice. Given the importance of the immune system on all the aspects of cancer progression and the association between, cancer, inflammation and obesity; our aim was to investigate the interaction between PCa and MeS on non-immunodeficient mice. We worked with male C57BL/6J mice that were fed with control diet (CD) or high fat diet (HFD) by 15 weeks. PCa TRAMP-C1 cells were injected subcutaneously in the right flank of the animals. Tumor size was measured 3 times a week during 30 days after inoculation. Animals were weighted once a week along the whole experiment. After 10 weeks, HFD fed mice were significantly overweight compared to CD fed mice. These mice also showed higher glucose and cholesterol levels on serum samples compared to CD fed mice. Regarding tumor growth, we found a significant increase in tumor volume on MeS group. Sixty days after cell inoculation we sacrificed the animals and collected tumors, lungs and liver tissue for RNA isolation and histopathological analysis. We found that tumors generated on HFD fed mice showed higher expression of CtBP1 and lower expression of E-cadherin (CDH1), a known tumor suppressor and CtBP1 target. Histological analysis showed no sign of micro- or macro-metastasis in soft tissues (the lungs and liver). Altogether, these results reinforced CtBP1 role as a crucial link that associates PCa development and MeS in mice independently of immune system.

Key words: Metabolic syndrome, CtBP1, Prostate Cancer.

Abstract: Pancreatic carcinogenesis is characterized by the activation of inflammatory signaling pathways. Numerous studies have demonstrated the role of essential fatty acids (EFAs) in pancreatic cancer initiation and progression, but the underlying molecular mechanisms have not been completely elucidated. Here, we studied the effects of two omega-3 EFAs, the eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) and the omega-6 fatty acid, the arachidonic acid (AA) on a human pancreatic cell line (PANC-1). We determined the release of interleukin-6 (IL-6) as inflammatory marker in supernatants from PANC-1 cultures using ELISA, as well as their gene expression by qRT-PCR. Cell viability (Rezasurin) and reactive oxygen species (ROS) production (DCFH-DA assay kit) by fluorimetry. Eicosanoids generation and lipid cell profile by High pressure liquid and Gas chromatography (HPLC and GC).We observed a significant reduction in cell viability in DHA and EPA compared to AA and control (ethanol) treatments ($P<0.05$). Moreover, we demonstrated an increased apoptotic levels in DHA and EPA treated cells in comparison with the control and AA treatment, probably mediated by ROS production ($P<0.05$). A diminution of IL-6 gene expression ($P< 0.01$) and liberation ($p< 0.02$) resulted after DHA and EPA treated cells. The release of proinflammatory eicosanoids: 13-HODE and 5(S)-HETE decreased on EPA and DHA treated cells compared with AA and control ($p<0.05$).Therefore, we demonstrated that omega-3 EFAs may reduce the growth of PANC-1 by several mechanisms that include significant increase of ROS production, diminution of lipid peroxides and down regulation of gene expression and secretion of inflammatory cytokines such as IL-6.

Keywords: pancreatic cancer, essential fatty acids, eicosanoids.

(1590) **ANTIPROLIFERATIVE EFFECT OF ESSENTIAL OIL OF *Artemisia mendozana* IN TUMOR CELLS B16F0.**

Elisa Millán (1), Emilio Lizarraga (2), Fernández Darío (1), López Luis Alberto (1)
(1) IHEM CCT-Conicet Mendoza. (2) Institute of Animal Physiology, Miguel Lillo Foundation, San Miguel de Tucumán.

The basic pathophysiology of cancer comprises aberrations at different points in the cell cycle. Due to the increasing incidence of cancer worldwide, there is an intense search for new therapeutic strategies to treat this disease. In this area, important efforts have been oriented to exploring the action of compounds of plant origin. *Artemisia mendozana var mendozana* (ajenjo), is a plant belonging to the Asteraceae family that growth in the piedmont of Mendoza province and it is used as a medicinal plant with antispasmodic and antifungal properties. The essential oil of ajenjo (EO) contains 28 compounds of which the higher concentrated are: artemisia alcohol 4.8%, α-thujone 5.1%, borneol 11.2% and bornyl acetate 43.7%. In this project the effect of EO was analyzed in the *in vitro* proliferation of B16F0 murine melanoma cells. For the assay the cells were cultured with vehicle DMSO (control) or 0.1- 0.25 µl / mL EO dissolved in DMSO for 72 h. The growth rate (GI) ± SE was calculated from 3 independent experiments. At 72 h of culture, the GI of the control was 6.37 ± 1.07 and with EO was: 4.57 ± 1.07 (A); 1.37 ± 0.18 (B) and 0.43 ± 0.03 (C) for 0.13, 0.2 and 0.25 µL / mL respectively. GI of B and C were significantly different to the control ($p\leq0.001$). These results show that EO, at concentrations, is a powerful inhibitor of the in vitro proliferation of B16 F0 cells.

General, Cellular and Molecular Biology (BM).

(301) **EFFECT OF FETAL BOVINE SERUM ON DELTA AMINOLEVULINIC ACID SYNTHASE EXPRESSION IN C3A HEPATOMA CELLS**

Sandra Milena Mora León (1), Leda Oliveri (1), Miriam Wald (2), Maria Victoria Rossetti (1), Esther Gerez (1)
(1) Centro de Investigaciones sobre Porfirinas y Porfirias. (2) BIOMED-UCA- CONICET.

Starvation or reduction of fetal bovine serum (FBS) in culture medium arrest cells in a quiescent state or in G_0 phase. In these cells, addition of serum induced numerous genes and proteins phosphorylation. Hepatic delta aminolevulinic synthase (ALAS1), the first and regulatory enzyme of heme pathway, is inducible at transcriptional and/or post-transcriptional levels through processes involving participation of tyrosines phosphorylation. FBS in chicken embryo hepatocytes culture medium affected ALAS1 expression forcing medium modifications to obtain a reproducible model.

The aim of this study was to investigate the effect of serum on ALAS1 expression. In the *in vitro* assays C3A cells were incubated in DMEM medium with different concentrations of FBS. mRNA and protein levels were determined at different time points by qPCR and western blot respectively.

FBS fasting (18h) provoked a significant drop in ALAS1 protein levels that increased when FBS was restored. Different concentrations of FBS (1, 2, 5 and 10%; 2h) increased ALAS1 protein levels progressively reaching an 800% increment at FBS 10% compared to control (C) group, nevertheless, mRNA levels were significantly lower than those observed in group C. Time course of FBS effect (FBS 2%; 5, 15, 30, 60 and 120min) showed increased ALAS1 protein levels up to 300% at 2h, whereas treatment with FBS+cycloheximide (0.1mM) didn´t modify ALAS1 levels respect to time 0. Pretreatment with a tyrosine phosphatases inhibitor, phenylarsine oxide (PAO) (5 and 40 uM; 30 min), and subsequent addition of FBS 2%, 2 h resulted in a decrease of ALAS1 35% and 80% at both PAO concentrations respectively.

These results suggest that FBS affected ALAS1 content due to an increase in protein translation and tyrosine phosphatases are involved in this induction

Keywords: delta aminolevulinic synthase 1, phenylarsine oxide, serum,

(420) **ISOLATION OF EXOSOMES FROM BREAST CANCER CELLS AND ITS ROLE IN THE INTERACTION WITH TUMOR ASSOCIATED MACROPHAGES.**

Maria Celeste Rodriguez-Baili, Germán Alejandro Gil
CIQUIBIC- CONICET. Facultad de Ciencias Químicas. Universidad Nacional de Córdoba

Worldwide, breast cancer is the most frequently diagnosed malignant cancer and the main cause of mortality in women. Despite the clinical benefits that the endocrine therapies offer to breast cancer patients, a significant rate develops resistance to those therapies. It is known that tumor associated macrophages (TAMs) promote tumor growth; however it is unknown if they play a key role in the development of endocrine resistance. Lately, there has been a greater interest in the nanovesicles called exosomes that are secreted by almost all cellular lines. These exosomes play an important role in cellular communication, growth of the microenvironment and tumor progression since it would allow the transmission of proteins, miRNA, RNA between cells; yet their mechanism and biology are still unclear. Here, we study different isolation techniques of the exosomes of the MCF-7 breast cancer cell-line and macrophagues KG-1 trying to understand if TAMs induce endocrine resistance *in vitro*. We used two different methods: ultracentrifugation and the commercial reagent “Isolation Exosomes Reagent (Invitrogen)”. MCF-7 cells and macrophagues were cultured until reached 70-80% of confluency and then, medium depleted of SFB exosomes was added and cultured for 48 h. Following the protocols of both methods, the supernatant was collected and the intact exosomes were obtained. To confirm the presence of the exosomes, we performed Electron Microscopy, and concordant images were obtained as previously described in bibliography. Additionally, the exosomes were detected by Western Blot with anti CD63 (a tetraspanin used for the detection of nanovesicles). Moreover, it was not observed the presence of Golgi markers, assuming that there is not contamination with other cellular vesicles. Exosomes of MCF-7 cells and macrophagues were

successfully isolated by both methods and we found that the commercial reagent is simpler, faster and its results are as good as one obtained by ultracentrifugation.

Keywords: Exosomes; TAMs; microenvironment; breast cancer.

(1580) **EVALUATION OF CIRCULATING TUMOR DNA AS A POTENTIAL LIQUID BIOPSY IN HEAD AND NECK TUMORS**

Fernando Orti (1), Alejandra Franco (1), Federico Cayol (2), Ana Jaén (3), Marcelo Figari (1,4), Cecilia Frecha (1), Javier Oliver (1)

The squamous cells carcinoma of the head and neck (SCCHN) affects the squamous epithelium of the oral cavity, tongue, oropharynx and larynx. In the world it represents the sixth most frequent cause of cancer. The main risk factors for the development SCCHN are smoking, alcohol, chronic inflammation and HPV. More than 70% of SCCHN are associated with mutations in the gene *TP53*. Circulating tumor DNA (ctDNA) are small fragments of nucleic acid originated by tumor cell turnover. CtDNA can be assessed in plasma, and offers the potential of a sensitive and specific biomarker for a host of applications including diagnosis or early detection of tumors, prognostic or overall survival, and predictive information on resistance and probability of lack of response to treatment.

The aim of the present study was to develop a laboratory workflow that allowed us evaluate the potential use of ctDNA can be used as a biomarker in head and neck cancers. Biopsy of primary tumor, blood and saliva were collected from 30 patients of SCCHN. DNA was extracted from tumoral tissue by Qiagen DNA Mini Kit. To obtain ctDNA isolation was performed from plasma and saliva obtained maximum 4 hours after blood collections. We tested several protocols and conditions to improve ctDNA levels. DNA concentration was measured on Bioanalyzer to obtain quality and Quantity. PCR of *TP53* exons were performed on tDNA and ctDNA. NGS libraries were done using Qiagen library kit. Tumor samples were sequenced by Sanger sequencing and ctDNA was sequenced using the PGM system at an average of 5000X. We improved ctDNA level carrying out a second plasma centrifugation at 6000 rpm. We were not able to obtain enough ctDNA from saliva. At the moment, two patients were evaluated by comparing sequencing results of both tDNA and ctDNA and we were able to detect same genetics variants. In conclusion, this preliminary results suggest that it is feasible to detect mutations in circulating free DNA in HNSCC.

Keywords: NGS, HnN, *TP53*, ctDNA, liquid biopsy.

(73) **IDENTIFICATION OF A NOVEL INDUCER OF SYNTHETHIC LETHALITY IN A HOMOLOGOUS RECOMBINATION BRCA1/2 DEFICIENT CELLULAR MODEL**

Paola Bernadette Campodónico (1), Natalia Soledad Paviolo (1), Sofía Carabajosa (2), María Florencia Pansa (2), María Belén Federico (1), José Luis Bocco (2), Vanesa Gottifredi (1), Gastón Soria (2)

The identification of compounds with selective tumor cytotoxicity can improve anticancer therapies. A promising strategy which takes advantage of the frequent impairment of DNA repair pathways in tumor cells is synthetic lethality (SL). For example, the loss of the Homologous Recombination Repair (HRR) capacity is frequent in breast and ovarian cancer. In those patients normal cells are HRR proficient and therefore, the accumulation of HRR substrates should selectively cause cell death in HRR defective cancer cells but not normal cells. Such hypothesis has been validated using Poly(ADP-ribose) polymerase inhibitors (PARPi), therefore prompting the systematic search for better and more specific SL inducers.

HRR loss is frequently triggered by defective or null expression of tumor suppressors BRCA1 and BRCA2. We designed a screening method to evaluate the specific ability of 684 kinase inhibitors to kill cancer cells with defects in BRCA1 and BRCA2 expression. Unexpectedly, the inhibition of one of those kinases caused the selective killing of BRCA2 defective cells with a much more modest effect in BRCA1 deficient cells. Such observations were validated in different cell lines and using commercial inhibitors of the same kinase (Ki), ruling out off- target effects. When treated with Ki, genomic aberrations and 53BP1 foci formation increased in BRCA2- but not BRCA1- depleted cells, suggesting that replication stress precedes cell death in Ki treated BRCA2-depleted samples. Finally, when combining sub-lethal concentrations of PARPi and Ki, SL was observed in BRCA2 (but not BRCA1) cells, suggesting that the treatments are not epistatic. Since the Ki sensitizes BRCA2-defective cells to sub-lethal doses of PARPs, the combined use of low doses of Ki and PARPi may improve the specific killing of BRCA2 defective tumor cells, sparing normal cells from unwanted collateral effects.

(573) **STUDY OF MECHANISMS UNDERLYING THERMOTOLERANCE ACTIVITY INDUCED BY CHLOROGENIC ACID IN C elegans**

Andrea Carranza, Ramón Asís

CIBICI, Facultad de Ciencias Químicas, UNC.

Chlorogenic acid (CGA) is a polyphenolic compound present in foods associated to different beneficial properties. In previous studies we demonstrated that CGA confers thermal stress resistance in *C.elegans* exposed to lethal temperature (37ºC). Its role in the stress resistance is not fully understood. Autophagy is thought to promote cell survival by providing fundamental building blocks to maintain energy homeostasis during starvation or stressful situations. On the other hand, hypoxia-inducible-factor (HIF)-1, a master transcriptional regulator of adaptation to hypoxia, plays a central role in stress resistance. In these sense, in the present study we have proposed to investigate the relationship between CGA, HIF-1 and autophagy. Results showed that CGA was unable to confer resistance to thermal stress in worms with loss of function of HIF-1 (ZG31) or with autophagy defects (cdc-48.2(tm659)). Moreover, preincubation of N2 worm with CGA before to be expose to thermal stress showed an increment in autophagy flux and HIF-1 activity. Finally, interactions between HIF-1 and autophagy underlying in CGA activity were explored by RNAi assay. Here, we demonstrated that autophagy and HIF-1 are mechanisms necessaries for CGA activity. All together, these preliminary results tend to explain the molecular mechanism that CGA activates in C elegans and evidence a possible hormetic response.

Keywords: C elegans, chlorogenic acid, autophagy, HIF-1, thermal stress.

(1267) **PRODUCTION AND CHARACTERIZATION OF A POLYCLONAL ANTIBODY AGAINST 14-3-3AcK49 TO STUDY 14-3-3 REGULATION.**

Frontini López Y.R.1; Masone D.F.1,2; Uhart M.1; Bustos D.M.1,3.

1Instituto de Histología y Embriología de Mendoza (IHEM – UNCuyo-CONICET); 2Facultad de Ingeniería (UNCuyo, Mendoza); 3Facultad de Ciencias Exactas y Naturales (UNCuyo, Mendoza).

Post-translational modifications (PTMs) of proteins affect almost all cellular processes. Among them, acetylation of lysines (K) has emerged recently as a reversible and dynamic PTM with important biological functions. The 14-3-3 proteins regulate the function and subcellular localization of thousands of proteins, through interaction with specific phospho- serine and threonine residues. The acetylation of a specific K (K49) which is part of the 14-3-3 binding pocket and is essential for its function, results in an inactive 14-3-3. To study its regulation and the crosstalk mechanism between acetylation-phosphorylation, we produced an antibody to recognize the above-mentioned AcK49 in 14-3-3. A chemically synthetized 15 amino acid peptide, including the acetylated K49, and conserved in all 14-3-3 paralogs, was coupled to Bovine Serum Albumin (BSA)

as carrier. This antigen was used to immunize rabbits in a pathogen-free animal facility (ISAL, UNL-CONICET). After 4 immunizations, blood was drawn from the animals, and the serum obtained by centrifugation. The later was tested by Dot- and Western blot against different 14-3-3 constructions. It recognized all the acetylated peptide or complete 14-3-3 forms (the antigen, an unconjugated synthetic peptide and a recombinant peptide coupled to Histone H3, all corresponding to the same sequence in 14-3-3, and *in vitro* acetylated 14-3-3), but not the non-acetylated recombinant 14-3-3. The serum did not recognize the recombinant peptide-H3 when blocked with the synthetic peptide. As expected, the preimmune serum did not recognize the antigen. This was the first step in a project to study 14-3-3 regulation by acetylation, which means regulation of regulators. We produced and characterized a polyclonal antibody that recognizes site-specifically the acetylation of 14-3-3 on its K49, which at the best of our knowledge is not commercially available.

Keywords: post-translational modification, 14-3-3 acetylation, regulation of regulators, crosstalk acetylation-phosphorylation

(88) **TUMOR SPECIFIC PROTEIN MAGEB2 REGULATES RIBOSOMAL BIOGENESIS**

María Fátima Ladelfa, Bryan Castaño, Gastón Amato, Franco Pascucci, Julieta Laiseca, Martín Monte
Laboratorio de Oncología Molecular, Dpto Qca Biológica, FCEN-UBA; IQUIBICEN-CONICET.

MageB2 is a tumor specific protein belonging to MAGE family. Previously, we reported MageB2 confers proliferative advantages to tumoral cells and localized in the cytoplasm, nucleus and also in the nucleolus, where the ribosome synthesis takes place. Here we study the relationship between MageB2 and the ribosomal biogenesis. In line with its nucleolar localization, immunofluorescence performed in an U2Os cell line inducible for MageB2 expression showed a higher number of nucleolus per cell (5.69 in control vs 6.93 in MageB2 expressing cells), suggesting an increase in nucleolar activities due to MageB2 expression. Ribosomal RNA (rRNA) gene expression is linked with cell growth and compromised in cancer cells. rRNA is synthesized in the nucleolus as a 47S precursor (pre-rRNA). We quantified the level of pre-rRNA by RT-qPCR and observed it was higher under MageB2 overexpression conditions. To complement this observation, we generated the HCT116 MageB2 KO cell line, using CRISPR/Cas9 technology. As expected due to MageB2 pro-proliferative role, cell proliferation was affected in the HCT116 MageB2 KO cell line and cell cycle analysis performed by flow cytometry showed a reduction in S phase percentages in comparison with its parental cell line (8.63% in HCT116 wt vs 4.02% in HCT116 MageB2 KO). Besides, we observed a 30% reduction in the pre-rRNA levels in the HCT116 MageB2 KO in comparison with HCT116 wt cell line.

rRNA precursor is transcribed by RNA pol I and controlled by multiple mechanisms. Activators as UBF and SL1 and repressors as HDACs and DNMTs regulate rRNA transcription to maintain optimal levels of cellular rRNA. In particular, HDAC1 is a known repressor of RNA pol I transcription. By performing immuneprecipitation assays we observed MageB2 strongly interacts with HDAC1. All together, our results suggest MageB2 could modulate ribosomal biogenesis, explaining, at least partially, the basis of it proliferative potential.

Keywords: MageB2, nucleolus, ribosomal biogenesis, pre-RNA synthesis

(95) **REGULATION OF MAGE TUMOR PROTEINS BY ONCOGENES AND ONCOSUPPRESSORS**

Franco Andrés Pascucci (1, 2), Gastón Amato (1), Julieta Laiseca (1, 2), Fatima Ladelfa (1, 2), Martín Monte (1,2)
(1) Lab. de Oncología Molecular- FCEN- UBA. (2) IQUIBICEN CONICET

MAGE-I genes expression is restricted to tumor and male germ cells. In the last years our group and others characterized different members of the Mage-I family, showing low functional redundancy, despite their high sequence homology.

Here we demonstrate that similarly to we reported for MageA2, MageC2 represses p53 transcriptional activity (3.0 fold) in a HDAC-dependent manner through trichostatin A (TSA) treatment.

We also identified two potential candidates able to regulate MAGE function: p14ARF tumor-suppressor and the oncogene RASV12. We observed that p14ARF expression significantly reverted both MageC2 and MageA2 repressive function of ectopically expressed p53 using DKO cells (murine embryonic fibroblasts $p53^{-/-}$, $mdm2^{-/-}$) and therefore in an Mdm2-independent fashion. Western Blot assay showed that MageC2 is degraded by p14ARF expression depending on proteasome activity (60% decrease reverted by MG132, a proteasome inhibitor). On the other side, immunofluorescence showed that MageA2 is relocalized to the nucleoli by p14ARF but no significant degradation was observed. On the contrary, RasV12 expression caused an increase in MageA2 and MageC2 protein levels. The effect of RASV12 on MageC2 protein was reflected in a greater inhibition of p53 when MageC2 is co-expressed with RasV12. Furthermore, the stabilization of MageC2 by RASV12 strongly prevents its degradation by p14ARF. Our observations suggest for the first time that MAGE-I tumor proteins could be targeted by oncogenes and tumor-suppressors. However, as demonstrated here, RASV12 oncogene can protect MageC2 from p14ARF degradation thus enhancing MageC2 ability in repressing p53 tumor-suppressor function. Altogether, our results uncover a novel notion where oncogenes could enhance their tumor-prone functions through MAGE proteins.

(942) **CHARACTERIZATION OF THE PERFORIN-LIKE PROTEIN FAMILY IN *BABESIA* SP.**

Martina Soledad Paoletta, José Manuel Jaramillo Ortiz, Ludmila Sol López Arias, Valeria Noely Montenegro, Marisa Diana Farber, Silvina Elizabeth Wilkowsky
Instituto de Biotecnología. CICVyA. INTA.

Bovine babesiosis is a tick-borne disease caused by protozoan parasites of the *Babesia* genus that affects livestock production worldwide. The study of proteins involved in their virulence is of special interest to understand the host-pathogen interaction and develop strategies to control the disease. The aim of this study was to characterize the Perforin-like protein (PLP) family of *Babesia* sp. since these pore-forming proteins are critical for pathogenesis and cell invasion. The PLP family in *Babesia* sp. has not been characterized yet.

Here we identified the *plp* genes in genomes of different *Babesia* species through detection of conserved motifs and domains using bioinformatics tools. All strains of *B. bovis* (n=2) and *B. bigemina* (n=4) had 6 and 8 genes respectively. Phylogenetic analyses were conducted on nucleotide and aminoacid sequences and showed that protein domains are highly conserved among *Babesia* species. Analysis of the secondary and tertiary structure of the functional domain of the PLP proteins showed that the conformation is conserved with the other proteins of the family suggesting that the *Babesia* proteins perform similar functions to the orthologous in other related organisms. Gene expression analysis in *B. bovis* merozoites showed that all the members of PLP family are expressed. Previously reported transcriptome analysis of *B. bovis* suggests that *plp1* has higher expression levels that the other PLP genes. Therefore, we selected this gene to further characterize it by expressing its functional domain in *E. coli*. Antibodies against recombinant PLP1 will allow to confirm its presence in merozoite lysates. Erythrocyte hemolysis assays will also be performed to evaluate the protein's lytic activity.

By combining bioinformatics as well as molecular and biochemical studies we expect to fully characterize the family of PLP proteins in *Babesia* and gain deeper knowledge of its role in this pathogen.

(1279) **IDENTIFICATION OF NOVEL PARTNERS OF THE SR-RELATED PROTEIN TbRRM1 IN *Trypanosoma brucei***

Jhenny M. Rojas, Analía G. Níttolo, Carolina P. Bañuelos, Juan I. Saborit, Valeria S. Tekiel, Daniel O. Sánchez, Gabriela V. Levy
Instituto de Investigaciones Biotecnológicas, Universidad Nacional de San Martín (IIB-UNSAM).

Previously, we have demonstrated that *TbRRM1* silencing leads to cell cycle block, apoptotic-like death and abnormal cell elongation in the procyclic stage of *T. brucei*.

TbRRM1 has three RNA binding motif, two zinc fingers and one small C-terminal SR domain potentially involved in protein-protein interaction. Recently, TbRRM1 has been shown to retain numerous RNAs in nucleus avoiding their translation. In addition, TbRRM1 was also associated with a few protein partners including core histones and several hot spot proteins. However, these results were obtained from an in-gel digestion assay, leading to a partial identification of the associated proteins.

Therefore, to obtain a more complete view of this interaction map we addressed the identification of TbRRM1 partners by liquid chromatography tandem-mass spectrometry approach (LC-MS/MS). For that purpose, we carried out the N-terminal tagging of one allele of the *TbRRM1* gene in RNAi-TbRRM1 procyclic cells. It is worth mentioning that parasites conditionally express the RNAi which corresponds to the 5´UTR fragment of the *TbRRM1* gene present only in the wild type allele, therefore allowing the unaffected expression of the tagged version. The tagged protein rescued the lethal phenotype caused by the depletion of the TbRRM1 protein, since no differences were observed in the growth curve of the induced parasites relative to the uninduced cultures. Moreover, immunofluorescence analysis with anti-flag monoclonal antibody and anti-TbRRM1 serum evidenced the correct localization of the tagged protein in parasites from TET+ cultures. Altogether, these results indicate that the tagging does not interfere with either protein localization or TbRRM1 function. Thus, pull down of TbRRM1 was carried out by anti-flag antibody and samples were subjected to LC-MS/MS. Partners identified in this work, will contribute to elucidate the function of TbRRM1 protein to gain a better understanding about Trypanosoma biology.

Keywords: RNA binding protein, protein interaction, gene expression regulation.

(165) **TbVPS15 PLAYS A ROLE IN VESICULAR TRANSPORT AND CYTOKINESIS IN Trypanosoma brucei**

Alejandra Cecilia Schoijet (1), Kildare Miranda (2), Tamara Sternlieb (1), Nadia Marisel Barrera (1), Patricio Genta (1), Milena Massimino Stepñika (1), Wanderley De Souza (2), Guillermo Daniel Alonso (1)
(1) INGEBI-CONICET-UBA. (2) Laboratorio de Ultraestrutura Celular Hertha Meyer, Instituto de Biofísica Carlos Chagas Filho and CENABIO, UFRJ, Rio de Janeiro, Brazil.

The class III phosphatidylinositol 3-kinase (PI3K) Vps34 is an important regulator of key cellular functions, including cell growth, survival, intracellular trafficking, autophagy and nutrient sensing. In yeast, Vps34 is associated with the putative serine/threonine protein kinase Vps15, however, its role in signaling has not been deeply evaluated. Previously, we have reported the cloning and characterization of both TcVps34 and TcVps15 in *Trypanosoma cruzi* and demonstrated that in this parasite these proteins function as a complex. In addition, we showed that TcVps34 plays a prominent role in vital processes for *T. cruzi* survival such as osmoregulation, acidification, endocytosis and vesicular trafficking, and that both TcVps34 and TcVps15 are involved in autophagy in this parasite. Here, we have identified the Vps15 orthologue in *Trypanosoma brucei*, named TbVps15. Knockdown of TbVps15 expression by interference RNA resulted in inhibition of cell growth and blockage of cytokinesis. Scanning electron microscopy revealed a variety of morphological abnormalities, with enlarged parasites and dividing cells that often exhibited a detached flagellum. Transmission electron microscopy analysis of TbVps15 RNAi cells showed an increase in intracellular vacuoles of the endomembrane system and some cells displayed an enlargement of the flagellar pocket, a common feature of cells defective in endocytosis. Uptake of dextran, transferrin and Concanavalin A were impaired. Finally, TbVps15 silencing affected both general kinase activity and PI3K activity, supporting the hypothesis that both proteins are conforming a complex as occurs in other organisms. In summary, we propose that *T. brucei* TbVps15 has a role in the maintenance of cytokinesis, endocytosis and intracellular trafficking in this parasite.

Keywords: *Trypanosoma brucei*, kinase TbVps15, cell cycle, endocytosis

(1280) **TbRRM1 SILENCING INDUCES CELL DEATH BY AN APOPTOTIC-LIKE MECHANISM IN THE BLOODSTREAM FORM STAGE OF *Trypanosoma brucei***

Analía Gabriela Níttolo, Carolina Paula Bañuelos, Daniel Oscar Sánchez, Gabriela Vanesa Levy
Instituto de Investigaciones Biotecnológicas, Universidad Nacional de San Martín (IIB-UNSAM)

Since transcription in trypanosomatids is polycistronic, the regulation of gene expression occurs mainly at the post-transcriptional level by RNA binding proteins. In our lab we study the gene expression regulation in *T. brucei*, particularly we focus on elucidating the function of the SR-related protein, TbRRM1.

Previously we have demonstrated that TbRRM1 is essential for the cell survival since its silencing produces cell cycle block, morphological alterations and transcriptional elongation impairment in procyclic form parasites. In the bloodstream form stage, silencing of *TbRRM1* by RNAi altered the growth curve with parasites displaying abnormal nucleus and kinetoplast configurations. Microscopic analysis of TbRRM1 depleted parasites, also showed detachment of the flagellum and increased proportion of linked parasites.

To further characterize the cell death process, we analyzed the mitochondrial membrane potential by Rho123 incorporation after *TbRRM1* silencing. Results demonstrated that TbRRM1 depletion decreased both the proportion of viable parasites and the cell population positive for Rho123. In addition, dual staining with FITC-Annexin-V and propidium iodide assays showed an increment of both early and late apoptotic population after RNAi induction. Moreover, cell cycle distribution analysis by flow cytometry evidenced an increase of the hypodiploid population after *TbRRM1* silencing.

Altogether, these results demonstrate that TbRRM1 depletion led to cell cycle death compatible with an apoptotic-like process. Interestingly, our results also showed that the apoptotic-like events began after the cell growth curve was altered, suggesting some kind of quiescence or lethargy after TbRRM1 depletion. Keywords: RNA binding protein, apoptotis, annexin-V, mitochondrial membrane potential, hipodiploidy.

(126) **CHARACTERIZATION OF THE CEST MOTIF (CHAPERONE FOR THE SECRETION OF E. COLI FROM TIR) IN TRYPANOSOMATIDS**

Camila Centeno Camean, Raúl Takada, Ignacio Durante, Gabriel Briones, Carlos A. Buscaglia, María De Los Milagros Cámara
IIB-INTECH UNSAM CONICET

Abstract: Using a bioinformatic approach we identified a small family of proteins restricted to trypanosomatids that present a 'CEST' domain, as it shows structural homology with CesT proteins (Chaperone for *E. coli* secretion of Tir). These proteins form a family of chaperones involved in the secretion of virulence factors through the type III secretion system (TIIISS) in enteropathogenic bacteria. Since CEST has a structural homology with protein templates from *Salmonella sp.*, we selected these bacteria as a biological model. We aimed to characterize the different CEST motifs of trypanosomatids by making a functional panning of the spectrum of motifs using a functional complementation model in *Salmonella sp*. We started by characterizing TCLP1 (Trypanosomatid CesT-like Protein 1) which accumulates in the flagellar pocket (unique site of surface protein export and nutrient uptake) of *T. cruzi* replicative forms and may be involved in nutrient uptake. Through biochemical, biological and immuno-cytochemical techniques, we verified that the expression of this parasite protein reverts the effects of the deletion of the homologous chaperone SicP of *Salmonella thyphimurium* on the TIIISS secretion dependent to the SptP effector. SptP presence was observed in supernatants from secretion assays. Infection assays followed by fluorescence microscopy demonstrated that complemented bacteria produce normal alterations of the cytoskeleton of host cells during the infection process. These results demonstrate that TCLP1 not

only has structural homology with bacterial chaperones but is also able to reverse the original phenotype of KO bacteria for its own chaperone. Given the socio-economic relevance of the diseases produced by trypanosomatids, the strategic location of TCLP1 and the importance of the CEST motif in enterobacteria, we hope that the results obtained may help to better understand the basic biology of these parasites.

Keywords: trypanosomatids, CEST, *Salmonella*

(923) **MULTIGENE TcTASV FAMILY: CHARACTERIZATION OF THE SUBFAMILIES TcTASV-B AND TcTASV-W IN DIFFERENT *T.cruzi* STRAINS.**

Mariana Rizzi, Yamil Masip, Valeria Tekiel (Instituto de Investigaciones Biotecnológicas

Instituto de Investigaciones Biotecnológicas (IIB-INTECH), CONICET - Universidad Nacional de San Martín (UNSAM), Buenos Aires, Argentina.

TcTASV is a *Trypanosoma cruzi* multigene family comprising about ~40 members and without orthologs in other trypanosomatids. All protein products of the TcTASV family have conserved amino and carboxy-termini, and a central variable core that allows partitioning TcTASV into four subfamilies: A, B, C and W. TcTASV-A and TcTASV-C subfamilies are the most numerous and were already characterized by our group (García, et al 2010; Bernabó et al 2013; Floridia et al 2016) but little is known about the less numerous TcTASV-B (2-10 genes) and TcTASV-W (2-4 genes) subfamilies. Our own previous results on sequences of the TcTASV family (Garcia et al, 2010) and the detailed inspection of more recently sequenced *T. cruzi* genomes, showed TcTASV-B genes in DTU-VI but not in DTU-I strains. This analysis was expanded here for a higher number of strains, by PCR and sequencing. On the other hand, we identified TcTASV-W genes in DTU-I, II, V and VI, by PCR and sequencing. TcTASV-B proteins are detected in trypomastigotes and extracellular amastigotes, while TcTASV-W is only expressed in trypomastigotes. Signals for surface localization and GPI anchoring are predicted *in silico* for both subfamilies. We determined that TcTASV-B is attached to the parasite membrane by a GPI anchor (but is not spontaneously secreted) in trypomastigotes, while TcTASV-W is not secreted nor attached to the parasite membrane by GPI, at least in the studied conditions. TcTASV-B is observed -by fluorescence microscopy- as discrete points on the membrane of both trypomastigotes and extracellular amastigotes. Interestingly, TcTASV-B and TcTASV-W proteins have divergent carboxy-termini domains that could explain the differences in protein location. Our final goal is to define which sequences determine the differential expression, traffic, cellular localization and, eventually, the function of the different TcTASV subfamilies. Supported by PICT 2014-1151 y PIP-2015-186.

*Keywords: T. cruzi,*TcTASV

(1135) **TRAFFICKING AND ASSORTMENT OF GPI-ANCHORED PROTEINS IN *TRYPANOSOMA CRUZI* CELL SURFACE.**

Giannina Alejandra Carlevaro, Juan Burgos, Oscar Campetella, Juan Mucci

Instituto de investigaciones Biotecnológicas (IIB), Universidad Nacional de San Martín (UNSAM)

At variance with mammals, trypanosomatids have a high percentage of proteins anchored by GPI in their plasma membrane. *T. cruzi* GPI-anchored virulence factors, such as *trans*-sialidase (TS) and mucins, are transported to the membrane by a non-conventional transport involving the contractile vacuole complex (CVC) prior to reaching the flagellar pocket and then the plasma membrane. Both proteins are only detectable in the CVC during the differentiation to the infective stage of trypomastigote. Once on the membrane, they are ordered in mutually exclusive domains: mucins are found in *"lipid rafts-like"* domains, whereas TS is not. Also, it is known that each protein has different GPI-lipidic composition. There is only scarce information concerning the signals that determine this arrangement on the plasma membrane or about the role of CVC on this novel transport pathway. Herein, we assessed the involvement of the lipid nature of the GPI anchor in this pathway and in the final membrane assortment. Recombinant *MucII* genes were constructed with either their native GPI or the TS-GPI signal, and cloned into the inducible expression vector *pTcIndex*. We found that protein intracellular trafficking was not modified. Using this regulated system with the recombinant *MucII* genes, we observed that both proteins were localized on the membrane with no accumulation in the CVC at low levels of expression. However, at higher expression levels constant protein accumulation was observed only in the CVC from 24h to 96h post-induction and not in other organelles of the secretory pathway. This suggests that CVC could function as a "bottle-neck". Then, the membrane arrangement of these proteins was analyzed. We have observed that the TS GPI-signal clearly changes the surface protein domain pattern both in size and distribution as compared to the native GPI-signal, thus highlighting the relevance of the GPI anchor in the final destination of surface proteins.

(1226) **MONOCLONAL ANTIBODIES AGAINST THE C-TERMINAL REGION OF *TRYPANOSOMA CRUZI* RIBOSOMAL P0 PROTEIN EXERT ONLY B1-ADRENERGIC BUT NOT MUSCARINIC FUNCTIONAL ACTIVITY**

Laura Mónica Tasso (1), Renato Chirivi (2), Ingolf Schimke (3), Gerd Wallukat (3), Leandro Simonetti (1), Silvia Longhi (1), Jos Raats (2), Karina Gómez (1)

(1) Instituto de Investigaciones en Ingeniería Genética y Biología Molecular "Dr. Héctor N. Torres" (INGEBI-CONICET), (2) ModiQuest B.V. Oss, The Netherlands, (3) Berlin Cures GmbH. Berlin, Germany

The chronic Chagas heart disease (cChHD) is the most frequent and severe manifestation of *T. cruzi* infection. Its pathogenesis is currently explained by two, non-mutually exclusive hypotheses: the immune response associated with parasite persistence and the molecular mimicry between host and parasite proteins. In this regard, we have previously demonstrated the presence of high antibody (Ab) levels against *T. cruzi* ribosomal P proteins, TcP0 and TcP2β proteins, which bear similarities with cardiac receptors β1 adrenergic (β1-AR) and muscarinic (M2-R), in cChHD patients´ sera. Since immunization of mice with TcP0 induced Abs against its C-terminal region (P015 peptide) that bind to and stimulate both types of cardiac receptors, we decided to explore its functional activity by the generation of anti-P015 monoclonal Abs (mAbs). After immunization of BALB/c and autoimmune-prone mice with P015-BSA, three anti-P015 mAbs were obtained. All of them recognized P015 peptide and P0 protein, as well as the other Tc ribosomal P proteins in ELISA and Western blot. Immunofluorescence assay showed a positive staining in the cytoplasm of the different *T. cruzi* stages. The functional activity of these mAbs was measured by pharmacological assay based on primary cultures of neonatal rat cardiomyocytes. Results showed that the mAbs induced a positive chronotropic effect ($p<0.0001$) which decreased in the presence of β1-blocker bisoprolol ($p<0.0001$) and H26R peptide (second extracellular loop of β1-AR) ($p<0.0001$), but not with M2-R peptide. These data clearly demonstrate that anti-P015 mAbs exert a specific β1-AR stimulatory effect. In agreement with these results, the confocal immunofluorescence of murine HL-1 cardiac cells showed a plasma membrane staining compatible with the β1-AR localization. Our results strengthen the role of antibodies against *T. cruzi* ribosomal P proteins in the pathophysiology of cChHD.

(1936) **POLARIZED LOCALIZATION OF SUBCELLULAR COMPONENTS IN PERITUBULAR MYOID CELLS**

Marra MF, Ibañez JE, Lopez L A.

IHEM UNCuyo- CCT-Conicet Mendoza, 5500 Mendoza.

In rat testes, peritubular myoid cells (PM cells) form the outer monolayer of the seminiferous tubule (ST). PM cells have characteristics of smooth muscle cells and participate in ST contraction. The study of MP cells has been carried out in crushed TS, so the 3D shape and distribution of cellular components are unknown. The objective of this work was to construct a 3D model of MP cells and determine

microfilaments, lipid microdomains and caveolae location using optical planes (OP) (36-40 cross sections of 0.4 µm). To achieve this objective, subcellular structures of the MP cells (alpha-actin filaments, plasma membrane, nucleus, lipid microdomains and caveolae) were identified by immunofluorescence. The OP were processed with Image-J sofware. 3D reconstruction of the OP allowed us to determine that MP cells has an irregular hexagon shape with a cleft in its apical face. Remarkably, MP cell has marked apical-basal polarization. In the apical face, most of actin filaments were distributed longitudinally (LF) (71% ± 0.9) and a few ones transversally (TF) (29% ± 0.9). In the basal face TF were the majority (72% ± 2.2) and LF (28% ± 2.2). In other hands, caveolae (identified with anti-caveolin-1), were located following actin filaments distribution. They are identified as isolated dots arranged in longitudinal lines (LL) or transversal lines (TL). In the apical face most of caveolae are in LL (n=9) in a number of 58 ± 1.5 dots/line. and in a few TL (n=5) in a number of 25 ± 1.5 dots/field. In the basal face most of caveolae are in TL (n=10) in a number of 60 ± 2.5 dots/line. and in a few LL (n=6) in a number of 28 ± 1.2 dots/line. Also the lipid microdomains are distributed throughout the cell surface, but show a higher concentration on the basal surface. These results indicate that MP cells are organized in an apical-basal polarity similarly to epithelial cells. The question is ¿Are MP cells in contact with two different environments?

IMMUNOLOGY (INNATE IMMUNITY) 2

(371) ROLE OF INNATE CD8⁺ T CELLS IN CANCER

Constanza Savid-Frontera, Natalia Soledad Baez, María Cecilia Rodríguez-Galán
Dpto. Bioquímica Clínica, Facultad de Ciencias Químicas, UNC. CIBICI- CONICET.

Innate CD8⁺ T cells were discovered about 10 years ago. These cells have particular phenotypic features (CD44^{hi} CD122^{hi} CD49d^{hi}) and exert cytotoxic activity mainly through NKG2D expression without specific antigen recognition. Innate CD8⁺ T cells express high levels of the transcription factor Eomesodermin and low expression of T-bet. They rapidly produce IFNγ after IL-12 and IL-18 stimulation due to constitutive expression of their receptors. Moreover, an antitumor role of innate CD8⁺ cells has been recently postulated both in mice and human. Our experiments using murine tumor cell lines demonstrate that systemic expression of these 2 cytokines (by hydrodynamic injection of their cDNAs) significantly attenuate tumor growth in WT mice compared to control group (injected with an empty cDNA) ($p<0.05$). Phenotypic analysis (based on the mentioned markers) of splenocytes and tumor-draining lymph node showed an increase of innate CD8⁺ cells in 12+18-treated mice compared to control group in both WT and OT-I mice ($p<0.05$).

Several chemokines and their receptors have been described to participate in the homing of different immune cells to tumors. Between them, CCR5 seems to be quite important for T cell extravasation. When we analyzed the expression of CCR5, we observed an increment in CCR5⁺ CD8⁺ but not in CD4⁺ T cells (by flow cytometry) only in mice treated with IL-12+IL-18 cDNAs compared to control mice ($p<0.05$). Accordingly, preliminary flow cytometry data revealed an increase in Percoll purified-infiltrating innate CCR5⁺ CD8⁺ T cells into B16 tumors of 12+18-treated mice compared to control group that correlates with an increase of total CD45⁺ cells infiltrating B16 tumor of 12+18-treated mice (microscopic analysis by immune fluorescence).

All together this data suggest that innate CD8⁺ cells may have a critical role in the control of tumor growth that could be important when TCR specific immune response is bypassed by tumors that down-regulates MHC-I expression.

Keywords: Cancer, Innate CD8⁺ T cell, tumor infiltration, IL-12 e IL-18, CCR5.

(666) A NEW PLATFORM TO DETECT INNATE IMMUNE RESPONSE MODULATING IMPURITIES (IIRMIS) IN THERAPEUTIC PROTEINS BASED ON THE USE OF MONOCYTE-DERIVED MACROPHAGES AND DENDRITIC CELLS

Eduardo F Mufarrege (1, 2), Sonia Ricotti (2), Sofía I Giorgetti (1, 2), Marina Etcheverrigaray (1, 2), Daniela Verthelyi (3)
(1) Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET). (2) Laboratorio de Cultivos Celulares, FBCB, UNL, Santa Fe, Argentina. (3) Laboratory of Immunology, Division of Biotechnology Review and Research III, Office of Biotechnology Products, Center for Drug Evaluation and Research, Food and Drug Administration, Silver Spring, Maryland, USA.

Biotherapeutics are agents produced through complex multi-step manufacturing methods. However, these products can contain contaminants derived from the host cell and manufacturing process that can trigger innate immune receptors, leading to the activation of immune cells and the secretion of cytokines and chemokines that could ultimately lead to the generation of anti-drug antibodies. To date numerous experimental approaches have been proposed to assess the risk of product immunogenicity and are mainly based on peripheral blood mononuclear cells (PBMC). However, macrophages and dendritic cells, which are rich in pattern recognition receptors (PRR) are present at very low frequency or absent in peripheral blood (PB). To address this, we evaluated the use of monocyte-derived macrophages (MØ) and dendritic cells (mo-DC) as screening tools to detect IIRMIs. Using purified PRR Agonists (PRRAgs) as model IIRMI and human IL-6 and IL-8 mRNA and protein as biomarkers for cell activation, we show that both primary cultures are more sensitive than PBMC in detecting IIRMI ($p\leq0.05$). Interestingly, MØ and mo-DC showed different limits of detection (LLOD) for individual PRRAgs. In addition, PRRAgs induced increased expression of a set of pro-inflammatory genes and the profile of genes induced varied with the TLR agonist and concentration. Finally, we tested the capability of human PBMC, MØ and mo-DC for detecting impurities in a commercially available product for the treatment of autoimmune inflammatory diseases. While PBMC samples were not activated by impurities present in the product, MØ and mo-DC showed a robust activation ($p\leq0.05$), even when low amount of product where added to the cell culture. In conclusion MØ and mo-DC constitute a suitable cell platform for testing impurities in therapeutic products, especially when these entities are present at such low levels not even detected by PBMC.

Keywords: Biotherapeutics, immunogenicity, impurities, cell-based assays.

(35) *Brucella abortus*-STIMULATED PLATELETS ACTIVATE BRAIN MICROVASCULAR ENDOTHELIAL CELLS

Ana Maria Rodriguez, Aldana Trotta (1), María Cruz Miraglia (2), María Victoria Delpino (3), Paula Barrionuevo (1), Guillermo Hernan Giambartolomei (3)
(1) IMEX. (2) INIGEM/CICVYA-INTA. (3) INIGEM.

Central nervous system invasion by bacteria of the genus *Brucella* results in an inflammatory disorder called neurobrucellosis. Blood-brain barrier activation is a common feature of human neurobrucellosis, but the underlying mechanisms are largely unknown. The aim of this work was to investigate the influence of *B. abortus* (*B.a.*)-activated platelets (PTL) on human brain microvascular endothelial cells (HBMEC). For this, supernatants (SN) from *B.a.*-stimulated human PTL were used to stimulate HBMEC. Expression of ICAM-1 (CD54) and secretion of IL-6, IL-8 and MCP-1 were evaluated to determine HBMEC´ activation. SN from *B.a.*-stimulated PLT induced a significant secretion of IL-6, IL-8, MCP-1 and the up-regulation of CD54 expression in a dose-dependent manner compared with SN from unstimulated PLT ($p<0.001$).To avoid the possible implication of *B.a.* outer membrane vesicles (OMV) we ultra-centrifuged the SN (to eliminate OMV). HBMEC were stimulated with ultra-centrifuge SN and we observed no differences on HBMEC' activation compared with non-centrifuge SN ($p>0.05$), demonstrating that a soluble factor released from PLT was implicated on HBMEC' activation. SN from heat-killed *B.a.*-stimulated PTL also activated HBMEC indicating that B.a.' viability was not necessary in activating PLT. Soluble CD40L was not implicated on HBMEC' activation, as an anti-CD40L antibody could not block cytokine secretion or ICAM-1 up-regulation. Treatment of SN with trypsin eliminate the effect ($p<0.0005$), demonstrating that the PLT effector is a protein. These results

demonstrate that *B.a.*-stimulated PTL can activate brain endothelial cells, and this could be implicated on the entry to B.a. to the central nervous system.

Brucella abortus – platelets - brain microvascular endothelial cells - Neurobrucellosis

(43) **ROLE OF HUMAN LUNG FIBROBLASTS IN THE *Brucella abortus* INFECTION BY INHALATION**

Iván Mathias Alonso Paiva, Florencia Muñoz González, Julieta Vanesa Focaraccio, María Cristina Ferrero, Pablo César Baldi

Instituto de Estudios de la Inmunidad Humoral (IDEHU, CONICET-UBA), Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires.

Inhalation of contaminated aerosols is one of the most common forms for human infection by *Brucella abortus*. Together with epithelial and endothelial cells, fibroblasts are an important component of the alveolar respiratory barrier. While the interaction of *Brucella* with human lung epithelial cells has been studied, its interaction with human lung fibroblasts remains unknown. In this work, we investigated the ability of *B. abortus* 2308 to infect and induce inflammatory mediators in a cell line of normal human lung fibroblasts (MRC-5). The cells were infected for 2 h and then incubated with gentamicin to kill extracellular bacteria (time 0 p.i.). At 2, 24 and 48 h p.i., cells were lysed to determine CFU of intracellular bacteria, and culture supernatants were collected at 48 h p.i. to measure cytokines. Results showed that *B. abortus* infects and replicates in lung fibroblasts and that its survival depends on a functional *virB* operon. The infection induced the secretion of interleukin-8 (IL-8) ($p<0.0001$), which secretion was mediated by p38 MAPK and NF-κB pathways, and monocyte chemotactic protein 1 (MCP-1) ($p<0.0001$), which secretion depended on p38 MAPK, NF-κB and PI3K pathways. Furthermore, the infection increased the gelatinase/collagenase activity ($p<0.0001$). The cytokine secretion did not depend on bacterial viability since heat-killed *B. abortus* and *B. abortus* lipopolysaccharide were also able to induce IL-6, IL-8 and MCP-1 secretion. In addition, the secretion of IL-6 and MCP-1 by fibroblasts increased significantly upon stimulation with conditioned medium (CM) from *B. abortus*-infected macrophages as compared to stimulation with CM from non-infected cells. These results suggest that human lung fibroblasts respond to *B. abortus* infection producing chemokines either directly or by stimulation with soluble factors secreted by infected macrophages.

Keywords: *Brucella*, human lung fibroblasts, cytokines, chemokines

(1012) **CATHEPSIN L3 FROM Fasciola hepatica induces IL-1β AND IL-18 SECRETION IN DENDRITC CELLS AND PROMOTES AN IN VIVO IFN-γ RESPONSE**

Daiana Celias (1), Leonardo Silvane (1), Ileana Corvo (2), José Tort (2), Cristina Motrán (1), Laura Cervi (1)

(1) Departamento de Bioquímica Clínica Facultad de Ciencias Químicas Universidad Nacional de Córdoba. CIBICI-CONICET. Córdoba, Argentina, (2) Laboratorio de I+D de Moléculas Bioactivas, Centro Universitario de Paysandú, Universidad de la República, Uruguay

Cathepsin L3 (CL3) is expressed in the juvenile stage of *F.hepatica* and has collagenolytic activity, however there is no information about its interaction with the immune system. The aim of this work was to study the ability of CL3 to modulate dendritic cells (DC) activation and its effect on adaptive immune response. DC were differentiated from bone marrow cells of C57BL/6 (WT) or NLRP3 KO mice with GM-CSF and cultured at different times with CL3. DC were pulsed with recombinant CL3, an inactive variant recombinant (rvCL3) or LPS/ATP. IL-1β and IL-18 secretion were quantified in supernatants by ELISA. Moreover, to study the ability of CL3 to induce a specific immune response, WT mice were intraperitoneally immunized with CL3 plus MPLA, three times at 48 h intervals. After 7 days of last immunization, lymph node cells (LNC) were recovered, re-stimulated with CL3 and IFN-γ production was studied. Statistical analyses were performed by ANOVA. To determine the uptake of CL3 by DC, we analyzed the presence of labeled CL3 into DC by confocal microscopy. Although after treatment, there was some colocalization between CL3 with lysosome, the presence of labeled CL3 in the cytoplasm of DC was evident. Besides, CL3 promotes IL-1β and IL-18 production in WT DC, at similar levels than those secreted by LPS/ATP-stimulated DC and this effect was not observed when DC were treated with rvCL3. However, when NLRP3KO DC were treated with CL3, IL-1β and IL-18 secretion were significantly diminished ($p\leq0,05$). On the other hand, increased levels of IFN-γ in CL3 re-stimulated LNC from CL3-MPLA immunized mice were observed ($p\leq0,01$).

Our results suggest that CL3 up-taking by DC induces IL-1β and IL-18 production-dependent on NLRP3, which in turn was dependent on CL3 enzymatic activity. This event could be related to the uptake of CL3 that promote the inflammasome activation. The up-regulation of these cytokines may be involved in IFN-γ production.

(1080) **AKAP350 REGULATES NATURAL KILLER CYTOTOXICITY BY CONDITIONING CELL POLARIZATION AT THE IMMUNE SYNAPSE**

Alejandro Pedro Pariani (1), Evangelina Almada (1), Florencia Hidalgo (1), Facundo Tonucci (1), Anabela Ferreti (1), Cristián Favre (1), Norberto W. Zwirner (2), María Cecilia Larocca (1)

The immunological synapse (IS) defines the interface between an immune cell and the cell with which it interacts. For natural killer (NK) cells, the formation of an IS is essential for cell activation and for directed cell secretion of lytic granules content into the target cell. The development of the IS in NK cells involves, after an initial interaction with the target cell, the formation of an actin ring at the IS, and the repositioning of the microtubule organizing center (MTOC) towards this site, which conditions the specificity of the final lytic response. AKAP350 is an A-kinase anchoring protein with a main role in the regulation of microtubule dynamics, which, in T-cells, participates in integrin LFA-1 clustering. The aim of our work was to analyze AKAP350 participation in the development of the IS in NK cells. We first characterized AKAP350 expression and localization at the MTOC in NK YTS cells. Control YTS cells and YTS cells with decreased expression of AKAP350 (AKAP350KD) were exposed to erythroleukemia derived KT-86 cells (10:1 ratio) for 3 h and their lytic response analyzed by flow cytometry. AKAP350KD cells lytic activity against their specific targets was significantly decreased (-50%*). Flow cytometry analysis indicated that AKAP350KD cells did not show any alteration at the initial YTS-KT86 conjugate formation or final YTS degranulation. Nevertheless, analysis by confocal microscopy showed that LFA-1 recruitment at the IS was inhibited (-41%*) in AKAP350KD cells. Furthermore, MTOC translocation towards the IS, analyzed as the distance between the YTS centroid and the IS (d_c) minus the distance between the MTOC and the IS (d_{MTOC}), was severely impaired by the decrease in AKAP350 expression. Our results indicate that AKAP350 conditions NK lytic capacity by modulating LFA -1 clustering and MTOC translocation towards the IS. Considering previous results, AKAP350 could modulate these processes by facilitating microtubule/actin cytoskeleton dynamics.

Cristian J. A. Asensio (1, 2), Rodolfo García (2)

(1) Biomed-Conicet-UCA (2) ICGEB

Abstract: During a systematic screening of the cytoplasmic proteome of bacterial-infected human macrophages (n=19) we detected a 110 KDa protein, identified by MS, antibodies and pI range as C23/NCL, which was down-regulated after infection (51.7 % at day 4, p=0.05). The triggering of the effect did not depend on bacterial viability suggesting an innate response to surface bacterial components. Little is known about the roles in the cytosol during infection of this major nucleolar phospho-protein. To understand this down-regulation, we developed novel biochemical and proteomic

assays including, protein kinase determinations. We followed putative upstream protein candidates in a NCL pathway studying kinases and other candidates. Several sensitive assays were developed to monitor its level and *in vivo* phosphorylation state. The down-regulation was not due to affected kinases regulating its phosphorylation state or to enzymes modulating its isomerization. Instead, it was due to increased partial cleavage of the full-length protein generating smaller fragmented forms. The cleavage was detected with higher sensitivity and more quantitatively with our assays compared to immunoblots. To understand the cleavage, we studied caspase activation. The results suggest that the cleavage is correlated with transient caspase activation and it could be a biomarker of apoptotic versus inflammatory signaling balance in the cytosol. It will be interesting to further study C23/NCL as a signaling hub integrating apoptotic, proliferation, nucleolar and immune/inflammatory signals both in infected and non-infected macrophages. Our sensitive assays will help studies in other cell types and cell compartments since the multitasking, acidic, RNA-binding and histone-binding C23/NCL is considered in cell cycle, gene expression and mRNA half-life studies and also as target for anti-cancer and anti-angiogenesis treatments. It is also a cell surface receptor for microbes and other ligands.

(1718) **ANTIGEN PRESENTING CELLS AND IMMUNOMODULATION MEDIATED BY DIFFERENT INFECTIVE STAGES OF *T. cruzi***

Brenda Gutierrez (1), Sebastián Biagini (1), Estela Lammel (1), Marcel Ramirez (2), Stella González Cappa (1), Carolina Poncini (1)

(1) IMPaM, UBA-CONICET, Facultad de Medicina. (2) Fundação Oswaldo Cruz, Rio de Janeiro, Brasil.

Dendritic cells (DCs) are key players mediating the innate and the adaptive immune response. Previously, we have reported that blood (b) trypomastigotes (Tp), negatively regulate the activity and function of bone-marrow derived DCs (CD-MO) *in vitro*. In the present work we compared the effect of bTp and metacyclic (m)Tp from culture, *in vitro* in two different subsets of DCs, CD-MO and XS106, a cell line derived from epidemic DCs (Mohan, 2005). Furthermore, we studied the extent of these results *in vivo* in the experimental model of infection after *T. cruzi* intradermal inoculation.

By flow cytometry, we better characterized the phenotype and functional properties of the XS106 cell line. We found F4/80, Ly6C, CD207, CD11b, CD11c, MHCII, CD40 and CD86 surface expression, confirming the myeloid origin of these cells in addition to a basal activation state, not affected by Tp (bTp or mTp). Moreover, by ELISA we detected TNF-α, and IL-10 downregulation in the presence of LPS+Tp, contrary to previous results reported in CD-MO. Co-culture of XS106 or CD-MO with bTp or mTp demonstrate that bTp presented enhanced infectivity in XS106 compared to mTp and to CD-MO.

The experimental model of infection with bTp and mTp showed differences in the recruitment of leukocytes into the site of infection. Animals inoculated with mTp displayed 100% of survival and no parasite detected in blood, while bTp inoculation induced 80% of mortality in addition to high parasitemia. Infection with mTp was confirmed by parasite detection at the site of infection in the skin and in the spleen by PCR. The challenge of mTp-infected animals by intraperitoneal infection with a lethal doses of bTp two weeks after the initial inoculation showed high activation of splenic DCs and control of the parasite load in blood and tissues. These results suggest that mTp obtained *in vitro* from epimastigotes and bTp triggered different early immune response.

(1751) **CASPASE-1/11 SIGNALLING IS CRITICAL FOR INDUCING CYTOTOXIC CD8+ T CELLS AGAINST *Trypanosoma cruzi* ACUTE INFECTION**

Augusto Paroli (1), Patricia González (1), Cintia Díaz-Luján (2), Roxana Cano (1), Susana Gea (1)

(1) CIBICI - CONICET - Dpto. Bqca. Clínica - FCQ – UNC. (2) INICSA - CONICET, Facultad de Medicina, UNC.

NLRP3 inflammasome has been reported as a protection mechanism to control *T. cruzi* infection during the innate immune response. Once it gets assembled, active caspase-1 cleaves the pro- IL-1β and IL-18 cytokines into its active forms. We previously demonstrated that infected *nlrp3-/-* in a similar way to C57BL/6 WT mice, exhibited similar parasitemias associated with Th1 and Th17 phenotype. Furthermore, high levels of transaminases and pro-inflammatory cytokines IL-1β and IL-6 were found in plasma of WT and *nlrp3-/-* mice. Here, we studied the hepatic parasite load and its relation with the liver histopathological status from WT, *nlrp3-/-* and *casp-1/11-/-* mice. Additionally, we comparatively analyzed the expression of IL-1R and IL-18R on CD8+ T cells and the expansion of IFNγ-, IL-17- and IL-10-producing CD8+ T cells during acute *T. cruzi* infection. Male C57BL/6 WT, *nlrp3-/-* and *casp1/11-/-* mice were infected with *T. cruzi* (Tulahuén).

The parasitic load was increased in both knock-out (KO) strains ($p<0.001$), presenting the *casp1/11-/-* mice the highest parasitism linked to a parasitemia peak at 21 dpi ($p<0.05$). Both KO strains presented minor hepatic leukocyte infiltration ($p<0.0001$) with augmented F4/80+ ($p<0.01$) and reduced CD8+ T cell numbers ($p<0.001$) compared to WT mice. As expected, the number of IL1R+ ($p<0.0001$) and IL18R+ ($p<0.001$) CD8+ T lymphocytes was strongly diminished in *casp1/11-/-* mice. Interestingly, IL-17+CD8+ T cells were only present in WT mice ($p<0.0001$) while IFN-γ- and IL10+CD8+ cells were detected in WT and *nlrp3-/-* ($p<0.001$). Last, plasmatic IL-18 quantification revealed that *casp1/11-/-* animals were not capable of increasing its levels, unlike WT and *nlrp3-/-* mice. These results clearly show that although NLRP3 partially participates in the response against the parasite, casp-1/11 play a critical role in the induction of adaptive immunity mediated by cytotoxic CD8+ T cells although probably also contribute to tissue damage.

Smilax campestris (*S. campestris*) is a medicinal plant wildly distributed in northern Argentina. It has been used in folk medicine for its anti-inflammatory and antioxidant effect. Activated macrophages produce pro-inflammatory mediators and reactive oxygen species (ROS) promoting the establishment of an inflammatory state. The NF-kB transcription factor pathway has a crucial role as a modulator of the inflammatory response. Previously we showed an anti-inflammatory effect of *S. campestris* aqueous extract on the production of pro-inflammatory cytokines (IL-1β, IL-6, IL-8), metalloproteinase-9 activity (MMP-9) and superoxide anion levels in LPS-activated THP-1 macrophages without exerting cytotoxic effects. In this study, we evaluated the effect of *S. campestris* aqueous extract on the production of the chemokine MCP-1 (ELISA) and the activation of IκB/NFκB transcription pathway (western blot) in a human monocyte-macrophage cell line, THP-1, differentiated with PMA. Cells were stimulated with *S. campestris* aqueous extract (10, 100, 1.000 and 10.000 ng/ml) in absence or presence of the inflammatory stimulus, lipopolysaccharide (LPS). The aqueous extract of rhizomes of *S. campestris* did not affect MCP-1 levels in absence of LPS. But the extract significantly decreased the production of the latter chemokine in human LPS-activated THP-1 macrophages ($p<0.05$). In addition, *S. campestris* extract (10.000 ng/ml) decreased NFκB-p65 levels in nuclear extracts ($p<0.01$), suggesting NFκB pathway is involved in the anti-inflammatory effect of *S. campestris* extract on THP-1 macrophages. In conclusion, we suggest an anti-inflammatory effect of *S. campestris* aqueous extract mediated by the inhibition of the NFkB-p65 transcription pathway affecting the production of

pro-inflammatory mediators, in human LPS-activated THP-1 macrophages. Our results provide evidence for the potential use of *S. campestris* aqueous extract as a therapeutic agent against several inflammatory diseases.

(539) **TRISOMY 21 CAUSES GLOBAL CHANGES IN GENE EXPRESSION IN REGULATORY T CELLS.**

Paula Araya (1), Katherine Waugh (2), Emiliano Roselli (1), Kelly D. Sullivan (2), Ahwan Pandey (2), Keith Smith (1), Mariana Maccioni (1), Joaquin M. Espinosa (1)

(1) Centro de Investigación de Bioquímica Clínica e Inmunologia - FCQ- UNC, Argentina. (2) Linda Crnic Institute for Down Syndrome, University of Colorado School of Medicine, Aurora, USA.

Trisomy 21 (T21) causes Down syndrome, due to the presence of an extra copy of chromosome 21 in some or all of an individual's cells. Individuals with T21 have alterations in disease incidence: these individuals have a higher predisposition of Alzheimer's disease, leukemia and autoimmune disorders, but a decrease susceptibility to solid tumors compared to euploid individuals (disomic, D21). Also, individuals with T21 present a constant activation of interferon signaling. Recently, we found that regulatory T cells (Treg) from individuals with T21 show an impaired suppressive capacity *in vitro* with no significant changes in the Treg phenotypic signature. In order to understand why T21 Treg are dysfunctional, we sorted CD4+ CD25hi CD127lo from peripheral blood of T21 and age-matched D21 individuals (n=6) and performed transcriptomic analysis by RNA-seq (using Clontech SMARTer Ultra Low Input RNA kit v4 followed by the Nextera XT kit to create the libraries that were sequenced on the HiSeq 2500). The comparison of T21 versus D21 Treg cells identified 134 consistent differentially expressed genes (DEGs, padj<0.1), with a disproportionate number of them being upregulated in T21 cells (91 up and 43 down). When we evaluated where the DEGs were located across the genome, we found, as expected, that many chr21 genes were overexpressed. However, ~73% of DEGs were located on other chromosomes, with no obvious contiguous domains of up- or downregulation. Next, we subjected T21 DEGs to upstream regulator analysis using Ingenuity Pathway Analysis (IPA) to identify putative factors contributing to consistent changes in gene expression (pval<0.05). IPA effectively identified canonical pathways important for maintenance of the expression of Foxp3 and therefore its functionality. Further functional studies should be performed to test these signaling pathways in T21 Treg to relate them to the diminished suppression capacity observed in Treg from individuals with T21.

(271) **CHARACTERIZATION OF IGG ISOTYPES AGAINST SEVERAL *Trypanosoma cruzi* ANTIGENS AND THEIR PROFILES ALONG CHAGAS HEART DISEASE STAGES**

Luz María Peverengo, Luz María Rodeles, Miguel Vicco, Estefanía Prochetto, Gabriel Cabrera, Iván Bontempi, Giuliana Lupi, Carolina Roldán, Lihue Gonzalez, Iván Marcipar

Laboratorio de Tecnología Inmunológica (FBCB-UNL) Santa Fe, Argentina

In murine infections, the inflammatory or regulatory profile of the immune response is associated with different IgG, but such association is less evident in humans. In Chagas heart disease (CCHD), several studies have corroborated the association of increased inflammatory cytokines levels in patients with advanced degrees of chronic disease but the profile of subclases of IgG has been scarcely reported. Tanking in mind that IgG1 is an inflammatory subclass while IgG2 and IgG4 have regulatory profiles, we hypothesized that these antibodies should be detected in different levels in asintomatic vs sintomatic patients. Then, we evaluated whether the severity of myocardiopathy is associated with an antibody subclass expression profile and if different antigens triggers different profiles.

A cross-sectional study involving 60 individuals who underwent complete clinical examination was performed. Patients were classified into three stages according to classification proposed by Storino et al.: CCHD stage I (n = 18), CCHD stage II (n = 23), CCHD stage III (n = 19). Serum samples were obtained for indirect ELISA assays that were performed to assess antibody levels for IgG subclasses (IgG1, IgG2 and IgG4) against two mimetic antigens (P2B, B13), a constitutive one (FRA) and total *T. cruzi* homogenate. For P2B, FRA and *T. cruzi* homogenates the higher reactivity was obtained with IgG2, followed by IgG1, and IgG4, respectively. For B13 the order of reactivity was IgG1> IgG2> IgG4. Along severity stages of CCHD, no significant differences in the levels of the different subclasses were detected for any of the antigens studied (p>0.05).

Although it is necessary to increase the number of patients in the sample, the homogeneity of the different antibodies subclasses levels against a heterogeneous group of antigens allow to infer that there is no association between subclass of antibodies and degrees of heart disease in humans.

(3) CONICET-Universidad de Buenos Aires, Instituto de Estudios de la Inmunidad Humoral (Idehu), LIBAP. Buenos Aires, Argentina.

Myasthenia Gravis (MG) is an autoantibody-mediated pathology. Many of these autoantibodies bind to the acetylcholine receptor in the neuromuscular junction, activating the complement system, thus generating damage and muscle weakness. We aimed to measure C3, C4 and C5a concentration in MG patients, and to analyze their potential as disease activity markers. We collected 63 samples from MG diagnosed patients (17 exacerbated) and normal matching controls (nc). There were 11 cases of paired samples. Disease status (remission: rem or exacerbation: ex) was determined by neurologic evaluation. We quantified C5a using a home-setup ELISA (expecting increases). C3 and C4 were measured with commercial radial immunodifussion plates (expecting decreases). There were no statistically significant (ss) differences in C3 and C4 mean values between groups (rem, ex, nc). But there was a ss correlation between C3 and C4 values in the 63 samples. This correlation was strong (r^2=0.9) in the group of patients in an ex period (p<0.0001). Among all MG patients, 10/17 (59%) showed high C5a values during an ex period. On the other hand, 27/46 (59%) showed low C5a values during a rem period (vs. mean value of nc). There was a ss increment in C5a values (p<0.05) in the ex group vs. nc, when analyzing the group of 11 paired samples. We couldn't find a ss mean difference or correlation when analyzing paired samples themselves. In conclusion, C3 and C4 were not good markers at differentiating disease status in MG patients, mainly due to the wide range of normal values they have. Alternatively, these two values have a very good correlation in ex MG patients, indicating that the two factors are being consumed simultaneously due to complement system activation by autoantibodies. The increment in C5a values in ex MG patients seems to be a promising disease activity marker, however, more patients need to be evaluated in order to achieve ss differences.

Abstract: Chronic lymphocytic leukemia (CLL) is characterized by the progressive accumulation of clonal B lymphocytes in blood, lymph nodes, spleen and bone marrow. Within lymphoid organs, CLL cells foster a protective microenvironment where they survive and proliferate. While almost every cell type in lymphoid tissues was reported to be modified by the leukemic clone, there is scarce information regarding the interaction of CLL cells with neutrophils. Tumor associated neutrophils (TANs), described in multiple types of solid tumors, facilitate cancer progression. Our aim was to determine if CLL cells were capable of modifying neutrophil phenotype and survival. To that purpose, neutrophils from healthy donor (HD) were co-cultured with purified leukemic cells from CLL patients (ratio 1:1) and apoptosis was assessed by flow cytometry using Annexin-V. Our results showed that CLL cells delayed neutrophil apoptosis at 24-72 h (n=15, p<0.05) and this effect was associated with the up-regulation of the anti-apoptotic protein Bfl-1. Protection of neutrophil apoptosis was similarly induced by CLL-conditionated media (CLL-CM) or transwell culture. Although there is not a unique phenotype for TANs, the downregulation of CD62L is a key feature of reprogrammation of neutrophils by tumor cells. Therefore we compared the percentage of CD16^{high}CD62L^{dim} subset in HD neutrophils cultured with or without CLL-CM for 24 h. We found an increase in the proportion of this subset induced by CLL-CM (n=10, p<0.05). Given that IL-10 and TGF-β have been implicated in TANs reprogrammation, we evaluated their role in the cross-talk between CLL cells and neutrophils. Our results showed that depletion of both cytokines from CLL-CM did not impair its anti-apoptotic effect but did impair its capacity to downregulate CD16 expression. Altogether these data show that CLL cells modify the survival and phenotype of neutrophils through the release of soluble factors.

(883) **A CORNEAL INJURY IN ONE EYE LEADS TO DISRUPTION OF MUCOSAL TOLERANCE IN THE OPPOSITE OCULAR SURFACE THROUGH A TRPV1- AND SUBSTANCE P-DEPENDENT NEUROINFLAMMATORY CIRCUIT**

Maximiliano Sebastián Miglio Rodríguez, Mauricio Guzmán, Irene Kaitelman, Florencia Sabbione, Analía Trevani, Mirta Giordano, Jeremías Galletti
Instituto de Medicina Experimental

Both ocular surfaces are considered functionally independent, thus an injury to one cornea is not expected to affect the opposite eye. However, we have observed that the tolerogenic immune response observed in mice after exposing one ocular surface to a foreign antigen is prevented if the opposite cornea is injured. Here we explored the underlying mechanisms for such inter-eye influence. First, we observed an increase in NFκB signaling in the conjunctival epithelium of the opposite eye (p<0.001), as measured by p65 intracellular localization by confocal microscopy 48 h after a corneal burn. At the same time point we also detected increased numbers of dendritic cells (p<0.05) and more activated T cells cells (p<0.05) in the contralateral lymph node. The fast kinetics of these changes and lack of lymphatic cross drainage from the eyes suggested that an inter-eye neuroinflammatory reflex could be involved. TRPV1 activation is an afferent signal for local neuroinflammation, whereas substance P (SP) released from the same sensitive terminals serves as an effector signal. In line with this hypothesis, instillation of TRPV1 antagonists on one eye before the corneal burn precluded the disruption of the fellow eye's tolerogenic response (p<0.05). Conversely, instillation of a SP receptor antagonist onto the fellow eye also precluded the inter-eye disruption (p<0.05). Moreover, a TRPV1 agonist instilled on one eye recapitulated the contralateral conjunctival NFκB activation and immune disruption (p<0.05). Remarkably, a clean 180º conjunctival incision, which severs most nerve endings, in one eye had a similar contralateral effect (p<0.05), whereas subconjunctival injection of complete Freund's adjuvant, which is a strong inflammatory stimulus but does not directly affect nerve terminals, did not (p>0.05). These findings suggests that nerve damage in one ocular surface leads to a protective change in the immune stance of the opposite eye that is mediated by TRPV1 and SP.

(1114) **IL-6 INDUCED BY SPONDYLOARTHRITIS SYNOVIAL FLUIDS MODULATES METALLOPROTEINASE-9 ACTIVITY IN SYNOVIAL FIBROBLASTS**

Maria Silvia Di Genaro (1), Rodrigo Blas (2), Alicia Munarriz (3), Rodolfo Pardo-Hidalgo (4), Héctor Tamashiro (5)
(1) División de Inmunología, Facultad de Química, Bioquímica y Farmacia, Universidad Nacional de San Luis e Instituto Multidisciplinario de Investigaciones Biológicas (IMIBIO), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), San Luis, Argentina, (2) Centro Médico MEDICI, San Luis, Argentina, (3) Centro Médico CENYR, San Luis, Argentina, (4) Centro de Rehabilitación Médica CER, San Juan, Argentina, (5) Clínica Bolivar, San Luis, Argentina

Spondyloarthritis (SpA) is the second most frequent chronic inflammatory arthritis. Fibroblast-like synoviocytes (FLS) are involved in SpA pathogenesis. The cytokine IL-6 has emerged as an important therapeutic target for rheumatic disorders. However, the IL-6-mediated mechanisms in chronic arthropathies are not fully understood. Metalloproteinase (MMP)-9 is associated with chronic inflammatory diseases. In previous studies, we demonstrated that synovial fluids (SF) of SpA patients induce early IL-6 production by FLS. The IL-6 blockade decreased MMP-9 activity of FLS. In the present work, we explored the role of IL-6 induced by SpA SF in regulating MMP-9 activity in FLS. The SF of SpA patients were pooled (n=9). Primary FLS or SW982 cell line were stimulated with SpA SF pool at dilution 1:10 in culture medium. The IL-6 function was blocked by the anti-IL-6 receptor antagonist tocilizumab(TCZ) (200ug/ml). Because IL-6 can activate JAK pathway, JAK-selective small molecule tofacitinib (1000 nM) was used to inhibit this pathway. The supernatants (SN) were collected after 48 h. The MMP-9 activity was determined by zymography. Cytokine levels in the SN were measured by ELISA. We found that in both primary FLS and SW982 cell line, TCZ decreased significantly MMP-9 activity induced by SpA SF (p<0.01, compared with FLS stimulated in absence of TCZ). Unexpectedly, JAK inhibition enhanced MMP-9 activity (p<0.001).To explore the mechanism of this paradoxical increase, SW982 cells were stimulated with recombinant human IL-6. We found that IL-6 induces MMP-9 activity in a dose-dependent manner. Moreover, IL-6 augmented IL-10 production, which decreased significantly by JAK inhibition (p<0.05). The results indicate that SpA SF recreate a microenvironment inducing IL-6 in FLS. Consequently, IL-6 provokes MMP-9 activity, but also it might drive a JAK-dependent mechanism, inducing IL-10 to control MMP-9 activity. These findings contribute to link IL-6 to the pathogenesis of SpA.

Keywords: spondyloarthritis, synovial fibroblasts, IL-6, MMP-9, synovial fluid

(1626) **B CELL RECONSTITUTION AFTER BONE MARROW TRANSPLANTATION IN PRIMARY IMMUNODEFICIENCIES**

Sabrina Soledad Rotondo, María Esnaola Azcoiti, Andrea Gómez Raccio, Liliana Bezrodnik, María Isabel Gaillard
Hospital de niños Ricardo Gutiérrez

Background: Hematopoietic stem cell transplantation (HSCT) provides a curative therapy for primary immunodeficiencies (PID). While

the timing and extent of Tcell reconstitution following transplant for PID has been studied in depth, less is known about the kinetics of B-cell development and long-term restoration of humoral functions. Materials and methods: We retrospectively analyzed immune reconstitution after HSCT in 11 paediatric patients with PID from our centre, with a follow-up ranging from 1 to 5 years. Lymphocyte subset populations (T $CD3^+$, $CD3^+/CD4^+$, $CD3^+/CD8^+$, $CD19^+$, $CD56^+$ lymphocytes) and B subsets (naïve, total memory, pre switch, post switch, transitional) were determined by flow cytometry and compared with reference values (RV). Serum IgA and IgM were analyzed by kinetic nephelometry and functional responses to tetanus toxoid (TT) and pneumococcal (Pn) vaccines by ELISA. Patients were followed from 1 to 5 years post HSCT. Results: B-cells counts normalized 6m post HSCT, median% (p25-p75): CD19:19% (10.5-33.75). Serum IgM and IgA normalized between 12-18m: median IgM: 61mg/dl (RV: 63-177); IgA: 88.5 mg/dl (RV: 52-150). Switched memory B-cells ($CD19^+CD27^+IgD^-IgM^-$) were restored early and reached normal values for age after 2 years (median 1/2/3/>4 yr: 3.2/5.2/8.7/9.0% respectively) RV: 5.5-14.9%. IgM memory B-cells ($CD19^+CD27^+IgD^+IgM^+$), remained significantly reduced long-term (median1/2/3/>4yr: 3.2/2.9/3.2/6.0%) RV: 9.5-17.2. B transitional decreased over time (median 1/2/3/>4 yr: 22.4/16.2/9.9/8.9%) RV: 5.1-8.7%. 7/11 suspended immunoglobulin replacement therapy (IgRT) and 6/7 had good TT response and 4/7 responded to Pn. Conclusion: Monitoring of phenotypic and functional changes on B-cells following HSCT may prove clinically relevant to tailor patients' care. In particular the analysis of IgM memory and switched memory B-cells are recommended before IgRT discontinuation.

Keywords: B cell reconstitution, PID

(1702) **CHANGES IN ANCA PATTERN POST SALT TREATMENT**

Estela Leonor Motta, Laura Dominguez, Marcelo Zamora
Sector Inmunología Laboratorio Central Hospital Oscar Alende Mar del Plata

Neutrophil anti-cytoplasmic antibodies (ANCA) associated with vasculitis are characterized by being directed against constituents of cytoplasmic granules of neutrophils. Previous studies have shown that treatment with high salt concentration prior to Indirect immunofluorescence (IFI) implies a decrease or loss of the P-ANCA pattern by removal of the cationic antigens to which they are directed, such as lactoferrin and mieloperoxidase (MPO). The aim of this work was to determine the effect of salt treatment on the ANCA patterns analyzed by IFI. Sera from three patients (1 PR3 / C-ANCA, patient with C-ANCA vasculitis under treatment, 1 MPO / P-ANCA, no clinical information and 1 PR3 / P-ANCA,vasculitis) The homemade slides were prepared by adsorption of a drop of blood, incubated 2 hours in a humid chamber at 37 ° C and fixed for 5 minutes with ethanol. For treatments with high salt concentration, the ethanol-fixed slides were incubated with TrisClH 50 mmol/l, magnesium sulphate 1 mol/l. IFI results on ethanol-fixed homemade slides showed that PR3 / P-ANCA serum (IFI titre: 1: 160) after saline treatment changed to C-ANCA (titre: 1:20), while in the commercial it remained as P-ANCA but with low title (titer: 1:20). Patient PR3 / C-ANCA maintained the same pattern and titer after the treatment in both slides and the serum that presented MPO / P-ANCA (titer IFI: 1: 640), in the homemade slides was negativized but in the commercial showed a P -ANCA titer of 1:40. The results obtained in the patient PR3 PANCA after saline treatment show a decrease in antibody titer or a change of pattern to CANCA possibly linked to different antigenic characteristics to which those antibodies are directed. We concluded that the PR3 PANCA antibodies could be directed against PR3 antigens with different characteristics or a mixture of antibodies directed against different specificities. New studies that address other antigenic specificities are needed.

(1705) **ANTICONVULSANT HYPERSENSITIVITY SYNDROME: A CASE REPORT**

Sebastián Leonangeli (1), Jazmín Azul Fraire (1), Jorge Loza (2), María Laura Godoy (2), Sonia Cecchin (2), Nilda Brizuela (1)
(1) Cátedra de Farmacología General, Facultad de Ciencias Médicas, Universidad Nacional de Córdoba. (2) Policlínico Policial, Córdoba.

A 25-year-old female presented a week evolution generalized, pruritic exanthema, which had begun on the neck with edema in eyelids and lips. She took cefadroxil 1 g / day for 24 hours after a biopsy due to a scleroatrophic lesion on the left leg. It switches to clavulanic amoxicillin for 24 hours, then it was discontinued and desloratadine and betamethasone was established.

After a week, she reported a fever episode of 39.5°C, and whitish vomiting. During the examination, mild dehydration, temperature increase, morbilliform exanthema, blistering scars on the anterior arm (three weeks of evolution), upper and lower limb edema were evidenced.

She had epilepsy, medicated with levetiracetam 1 g / day for a year, decreased to 500 mg / day 15 days prior to consultation; and oxcarbazepine 300 mg / day for a month, increased to 600 mg / day 15 prior.

Hepatitis was demonstrated in laboratory results, AST 413 ALT 367, leukopenia 3400 (47/0/0/44/9), platelet count normal, VDRL/ HIV/ HBV/ HCV serologies were negative.

Patient was hospitalized. Oxcarbazepine was discontinued, while dexamethasone and diphenhydramine treatment was instated.

She was discharged after 5 days of treatment. Fexofenadine and meprednisone were given ambulatory.

Key words: Hypersensitivity, Anticonvulsants, Epilepsy, Oxcarbazepine

(1869) **COCAINE SELF-ADMINISTRATION MODULATES PERIPHERAL IMMUNE CELLS LEVELS AND THEIR CB2 RECEPTOR EXPRESSION**

María Amparo Assis (1,2,3), Raquel Santos-Toscano (3), Marcos Ucha-Tortuero (3), Alejandro Higuera-Matas (3), Pedro Gabriel Carranza (1,2,3)
(1) IMSaTED, CONICET-UNSE-CONICET, Santiago del Estero, Argentina. (2) Facultad de Ciencias Médicas, UNSE, Santiago del Estero, Argentina (3) Departamento de Psicobiología, Facultad de Psicología, UNED, Madrid, España.

The immune system (IS) is able to modulate several central nervous system (CNS) functions (including learning, memory, neural plasticity and neurogenesis) by complex interactions among glia, neurons, neural precursor cells and peripheral immune cells (particularly T-cells and macrophages). In parallel, CNS acting drugs, such as psychostimulants, are able to modulate the IS. CB_2 cannabinoid receptors are expressed both in CNS and IS, and have been associated with cocaine- induced effects. The aim of the present work was to study the levels of peripheral T- and B-cells and macrophages, as well as their CB_2 receptor surface expression after cocaine treatment. Lewis rats were trained during 3 weeks in cocaine (1 mg/kg/infusion, i.v.) or vehicle self-administration. Twenty-four hours later, the rats were sacrificed and the spleens were removed in order to obtain spleen mononuclear cells (SMC). In cocaine self-administered rats, we observed a macroscopic splenomegaly reflected in augmented relative spleen weight ($p<0.001$). We consistently found increased levels in the number of SMC/spleen ($p<0.001$) after cocaine self-administration, so that the SMC/splenic index ratio was also increased ($p<0.05$). Flow cytometry (FCM) analysis of SMC subpopulations revealed that T-cells percentage was not modified after cocaine, although the absolute number showed a remarkable elevation ($p<0.001$). Conversely the B-cells percentage significantly decreased ($p<0.05$), while the absolute levels had also increased after cocaine ($p<0.001$). Thus, the T-/B-cells ratio showed an increment following cocaine ($p<0.05$). Macrophages levels, both relative ($p<0.05$) and absolute ($p<0.001$), were elevated after cocaine self-administration. Finally, after cocaine self-administration, CB_2 expression increased on T-cells and macrophages ($p<0.05$ and $p<0.01$) but not on B-cells. These results open new research perspectives concerning the influence of cocaine on the immune system.

(1519) **EARLY BACKGROUND ADAPTATION IN THE MEDAKA *Oryzias latipes***

Tomás Delgadin (1,2), Clara Sacks (1), Julieta Sallemi (1), Maria Paula Di Yorio (1,2) Daniela Pérez Sirkin (1), Juan Fernandino (3), Paula Vissio (1,2)
(1) DBBE-FCEN-UBA. (2) IBBEA-CONICET. (3) IIB-INTECH (Chascomús)

Background colour adaptation is both an endocrine and a physiological response to the surrounding environment that many vertebrates are able to display owing to changes in specialized cells called chromatophores present in the skin. However, it is not known if such a process of adaptation may take place during early developmental stages and how they can influence other aspects of development such as growth. The aim of this work was to evaluate if background color adaptation occurs during early developmental stages in the medaka and its possible effects on growth. Thus, we analyzed the number of melanophores, a type of chromatophore, in the head, from medakas adapted to 18, 21, 25, 40 and 60 days post fertilization (dpf) to white or black background. To do this, medaka eggs were taken from 2 to 3 spawnings of different male and females medaka pairs for each timepoint and randomly assigned to black or white backgrounds, reared in Petri dish until hatching and then transferred to tanks of the same background till sampling. Additionally, total length and bodyweight were registered. Data were analyzed by two way ANOVA followed by post hoc comparison. P-values were corrected to avoid type I error. Black adapted medaka larvae presented more head melanophores than white adapted ones ($p=0.0001$). This difference is not present at 18dpf ($p=0.118$) but begins at 21dpf ($p=0.0292$) and increases at 25dpf ($p<0.0001$), 40dpf ($p<0.0001$) and 60dpf ($p=0.0107$). No differences in total length and bodyweight were detected between black or white adapted medaka larvae ($p>0.05$). These results showed that background adaptation occurs early during development and the biological processes by which this takes place must be present at least as early as 21dpf.

(2) Instituto de Investigaciones Biológicas, Universidad Nacional de Mar del Plata (UNMdP), Mar del Plata,Buenos Aires, Argentina.

Abstract: The general objective of this work was to evaluate the effect of gibberellic acid (GA) supplementation on *Apis mellifera* colonies over the production of queen bee cells and hypopharyngeal glands development from nurse bees. We worked with 2 starter colonies (Langsthrot hives) subjected to the vertical semi-orphaned method of production of bee queen cells. Each starter colony received a specific treatment: colony 1 (i1) was the control group and fed with 200 ml of 66% sugar syrup only; colony 2 (i2) received 25 uM GA in 200 ml of 66% sugar syrup. Each beehive received 10 applications of their respective treatment every 3 days. For each colony, 24 larvae were transferred to the upper body the day after the first treatment was applied. Five days after, the total number of accepted larvae was recorded, defined as royal cell that had been sealed. After the 5th application, 250 nurse bees were collected from royal cells to measure the weight of their heads (indirect quality estimator of the hypopharyngeal glands development). In the laboratory, 50 bees were randomly selected from each treatment, the heads were dissected and their weights were recorded by analytical balance. Wilcoxon test and t-test were used to determine if there were differences in the production of cells and head weights respectively. In the i2 colony, higher percentages were obtained in the efficiency of royal cells ($p <0.05$ - Wilcoxon Rank sum test, $W = 0$, $P = 0.01091$) and in the weight of the bees' heads (Sample t-test, $t = -3.1241$, $df = 100.98$, $P = 0.002328$) compared to the control colony i1.

Keywords: *Apis mellifera*, brood method, dietary supplement

(239) **EFFECT OF THE EXTRACT OF TOMATO (*Lycopene)* IN THE PEROXIDATION OF RAT LIVER MICROSOMES**

Javier Barberón (1), María Ventura (1), Mariana Gavazza (1), César Savignone (1), Valeria Becerra (2), Pedro Zeinsteger (1), Alejandro Palacios (1)
(1) Cátedra de Bioquímica - Facultad de Ciencias Veterinarias, Universidad Nacional de la Plata. (2) Cátedra de Biología - Facultad de Ciencias Veterinarias, Universidad Católica de Cuyo Sede San Luis.

Lycopene is the important pigment responsible for the characteristic red color of tomato; it has attracted attention due to its biological and physicochemical properties, especially related to its effects as a natural antioxidant. The objective of this study was to investigate the antioxidant effect of the lycopenes obtained from the extract of tomato on the peroxidation of hepatic microsomes membranes. Rat liver microsomes where incubated with different concentrations of extract (2, 4, 6, 8 μg) in an *in vitro* non-enzymatic ascorbic acid-Fe^{+2} system in order to determine the oxidative effect on membranes and to quantify peroxidation level in standardized conditions. Peroxidation was quantified in a liquid scintillation counter Packard 1900 TR by chemiluminescence in cpm (counts per minute). Microsomal membranes without extract were used as controls. Analyzing the effect of lycopene (tomato extract), was observed that the total cpm/mg protein originated from light emission: chemiluminescence, was statistically lower in samples obtained from lycopene group than in the control group (without lycopene), the antioxidant effect found was not dependent concentration.

(52) **EFFECTS OF DIETARY PROTEIN:LIPID RATIO ON GENES IMPLICATED IN SOMATIC GROWTH, LIPID METABOLISM AND FOOD INTAKE IN PEJERREY FRY (*Odontesthes bonariensis*)**

Juan Ignacio Bertucci (1), Ayelen Melisa Blanco Imperiali (2), Juan Carlos Navarro (3), Mario Oswaldo Tovar (1), Suraj Unniappan (4), Luis Fabián Canosa (1)
(1) Instituto de Investigaciones Biotecnológicas - Instituto Tecnológico Chascomús (IIB-INTECH). (2) Departamento de Fisiología (Fisiología Animal II), Facultad de Biología, Universidad Complutense de Madrid, Madrid, España. (3) Instituto de Acuicultura Torre de la Sal-Consejo Superior de Investigaciones Científicas (IATS-CSIC), Castellón, España. (4) Laboratory of Integrative Neuroendocrinology, Department of Veterinary Biomedical Sciences, Western College of Veterinary Medicine, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

Abstract: Pejerrey is a freshwater fish from south America with potential as an aquaculture specie. With the major goal to develop its aquaculture, the aim of this study was to determine the best protein:lipid ratio of diets to achieve higher growth rates in first stages of development. To do this, pejerrey fry (30 days after hatching) were divided in three groups, each one fed per 60 days with an experimental diet containing one of the following protein (P):lipid (L) ratios: 40% P – 12% L (Diet 40P12L); 40% P – 20% L (Diet 40P20L); 50% P – 12% L (Diet 50P12L) and 50% P – 20% L (Diet 50P20L). After trial, RNA from head, trunk and tail were collected to analyze the gene expression of components from the GH-IGF axis. Also, the gene expression from the enzyme Δ6-desaturase (involved in lipid metabolism) and from the anorexigenic peptide nesfatin-1 were measured. Data were analyzed by two-way ANOVA, followed by post hoc Holm-Sidak test at a significance level of $P < 0.05$. Fry fed with diets 40P12L and 50P12L showed the highest somatic growth ($p<0.05$) and highest growth hormone (*gh*) gene expression ($p<0.05$). The total amount of PUFAs from the serie n-6 was higher in group fed on diet 50P20L ($p<0.05$). The *Δ6-desaturase* gene expression was higher in head of those fry fed on diet 40P12L. The expression levels

of *nucb2/nesfatin-1* and *gh* in head, and of *nucb2/nesfatin-1* and the *ghr-I* and *ghr-II* in body follow the same patterns. In conclusion, diets with 12% of lipids produces the higher fry growth compared to those diets containing 20%. Comparing diets with 12% of lipid content, the higher percent of proteins (50%) generates the higher growth-rates. In these groups, mRNA expression from GH-IGF axis could be related with the promotion of somatic growth. The different expression patterns of *nucb2/nesfatin-1* in head and body of pejerrey fry seems to indicate some effect not only related to food intake regulation.

Keywords: Δ6-desaturase, growth hormone, lipid, nesfatin-1, protein.

(1364) **EFFECTS OF EXTRACTS OF BROWN SEAWEEDS AS DIETARY ADDITIVE ON THE METABOLIC PROFILE AND FEED DIGESTIBILITY IN *Artemesia longinaris***

María Laura Espino (1), Natalia Soledad Arzoz (2), Ana Cristina Díaz (2), Susana María Velurtas (1), María Alejandra Marcoval (1), Jorge Lino Fenucci (1)
(1) Instituto de Investigaciones Marinas y Costeras (CONICET-UNMdP). (2) Comisión de Investigaciones Científicas.

A study was conducted to evaluate polysaccharide extracts of brown seaweeds as dietary additive for prawns (5.9±1.30g). The aim of this study was to compare zootechnical parameters, metabolic profile and apparent digestibility of *Artemesia longinaris* fed diets with 0; 1 or 2g of polysaccharide extracts of *Undaria pinnatifida* or *Macrocystis pyrifera* (C, U1, U2, M1, and M2, respectively), and with 0.5% Cr_2O_3 as inert marker. To determine apparent digestibility, feces were collected during the last two weeks of the trial, and to measure metabolic variables (glucose, triglycerides, cholesterol, total proteins), haemolymph was extracted at the end of the experiment. After 30 days of feeding in all treatments, the survival was superior to that considered as acceptable in commercial culture, percentages varied between 60% and 79.2% and no significant differences were found between treatments. Percentage of increment in mean weight of prawns under different treatments varied between 8.5 and 16.7%, with higher values in animals fed with *U. pinnatifida* extract (U1 and U2). Apparent digestibility decreases significantly with the addition of 2g of both extracts, although this effect was lower in those animals feed U1 and U2. Regarding the determination of metabolites, no significant differences were found in levels of plasma metabolites in animals feed with *M. pyrifera* but a significant increase was observed in total protein and cholesterol concentrations in animals feed with diet supplemented with 1g of *U. pinnatifida*. These results suggest that, the use of polysaccharide extracts of *U. pinnatifida* is feasible as additive in diets for the prawn *A. longinaris*. The optimal level of inclusion may vary depending on the algal species, for culture this species, the recommended concentration should be 1g, since it is the one that produces increase in mean weight, without interfering with apparent digestibility.

Keywords: *Artemesia longinaris*, seaweeds, apparent digestibility, metabolic profile.

(688) **ROLE OF DP53 IN METABOLIC HOMEOSTASIS AND AUTOPHAGY UNDER NUTRIENT STRESS**

Maria Clara Ingaramo, Andres Dekanty
Instituto de Agrobiotecnología del Litoral

The ability of an organism to adapt to nutritional stress is crucial for its survival. We have previously shown that the transcription factor Dp53 plays a central role in metabolic remodeling in Drosophila. Depletion of Dp53 activity specifically in the adipose tissue accelerates the consumption of main energy stores, reduces the levels of sugars in the animal, and compromises organismal survival upon fasting. In this work, we aim to investigate in more detail the role of Dp53 in response to nutrient deprivation. By using a combination of transgenic reporter lines and fluorescent dyes we found that Dp53 is required for the induction of autophagy, a conserved catabolic process which is central in the nutrient stress response. This function of Dp53 appears to be tissue specific as depletion of Dp53 protein levels and/or activity in the fatbody strongly reduced starvation-induced autophagy. Interestingly, the role of Dp53 in modulating autophagy appears to be a systemic function rather than through cell-autonomous mechanisms. Insulin-like peptides (dIlps) regulate physiological and metabolic responses to nutrients in Drosophila and, consistently, we observed differences in dIlps expression levels and insulin signaling when Dp53 activity was compromised in the fatbody. From these results, we propose that Dp53 is required in the fatbody to remotely modulate insulin secretion and/or production in the brain therefore providing mechanisms for rapid adaptation to starvation conditions.

Keywords: Dp53, Drosophila, autophagy

(606) **ACARICIDAL ACTIVITY ON *VARROA DESTRUCTOR* OF TWO ESSENTIAL OILS OF *CYMBOPOGON NARDUS* FROM TWO DIFFERENT COUNTRIES AND THEIR CITRONELLA MONOTERPENOID**

Pablo Darian Gimenez Martinez, Facundo Ramos, Martin Eguaras, Rosa Maria Alonso-Salces, Matias Maggi, Sandra Fuselli
CIAS UNMDP

Varroosis caused by *Varroa destructor* is considered the greatest disease of the honeybee. Mite control is mainly based on the application of synthetic acaricides but its continuous use over time leads to a selection pressure causing several foci of resistance and contamination of bee products in the entire world. A range of essential oils have been found to exhibit acaricide activity against *V. destructor.* The main objective of the present work was to evaluate the acaricidal activity on *V. destructor* of the essential oil *Cymbopogon nardus* obtained from Argentina and India, as well as the activity of the major component of this oil, the Citronelal monoterpenoid. The LC_{50} of both essential oils and the compound was estimated by using a full exposure method. Oils and component concentrations between 0 (control) to 40 µl/ml were applied in the inner surface of Petri dishes. Alcohol was used as solvent, after itsevaporation, 5 adult worker bees and 5 mites were placed with a feeder containing water and candy in each Petri dish. Capsules were incubated at 30°C and 70% RH. The mortality of mites and bees at 24, 48 and 72 hours was recorded for each treatment. By probit analysis the LC_{50} was estimated for each essential oil and citronelal compound, expressed in µl of compound/ml. A selectivity ratio, calculated as *A. mellifera* LC_{50}*/V. destructor* LC_{50}, was determined for each treatment at each observation. The essential oil from India and the Citronelal compound were the most toxic against mites and bees (LC_{50} 2.38 µl/ml and <2.5 ul/ml, and 2.48 ul/ml and 3.61 ul/ml respectively). *C. nardus* oil from Argentina presented low toxicity in adult bees (>10µl/ml) and promising acaricide effect on mites (4.26 ul/ml). These results show that the essential oil of *C. nardus* from Argentina could be a succesfull alternative in the control of Varroosis.

Keywords: *Varroa destructor, Apis mellifera*, Essential Oils, Acaricidal Activity.

(1442) **INTESTINAL MICROBIOTAMODULATION INDUCED BY ANTIBIOTICS AND TANNINS-BASED FEED ADDITIVES UNDER EXPERIMENTAL AND COMMERCIAL CONDITIONS IN POULTRY**

Juan Diaz Carrasco (1), Enzo Redondo (1), Natalia Pin Viso (2), Leandro Redondo (1), Marisa Farber (2), Mariano Fernandez Miyakawa (1)
(1) INTA – Patobiología. (2) INTA – Biotecnología.

Antibiotic growth promoters (AGPs) have been used for decades in animal production as a means to maintain animal health and improve feed efficiency. Global concern about development and transference of antimicrobial resistance is rising and so the development of alternatives to AGPs is urgently needed. Information about the effects of phytogenic compounds on chicken intestinal microbiota is required to understand the potential of these bioactive natural products as alternatives to antibiotics. The aim of this study was to assess the impact of a blend of chestnut and quebracho tannins in the microbiota of chickens by high-throughput sequencing (HTS) of 16S rRNA gene amplicons.

Cecal contents were obtained at 21 and 40 days of age from chickens raised under experimental or commercial conditions. In both environments, two treatments groups were compared: tannins and bacitracin supplemented birds. DNA was extracted from each

pooled cecal sample and the V3–V4 region of the 16S rRNA gene was amplified. HTS was performed in the Illumina MiSeq platform. Bioinformatics analysis was done with QIIME and STAMP software.

A significantly different microbial profile was found between experimental and commercial samples and also between the two sampling ages analyzed. Significant differences in the diversity metrics across dietary treatments were detected in both environments. Tannins increased *Firmicutes* to *Bacteroidetes* ratio, a parameter linked to feed conversion efficiency, in both experimental and productive conditions. This was mainly due to the growth of members of order *Clostridiales* and genus *Lactobacillus* and the decrease of genus *Bacteroides*. Tannins also increased the relative abundance of other potentially probiotic genera as *Bifidobacterium* and *Enterococcus*. Further studies using whole shotgun sequencing are required to go in deep in investigating the effects of alternative feed additives and AGPs on intestinal microbiota of poultry.

Keywords: feed additives, tannins, poultry, high-throughput sequencing, intestinal microbiota.

(1734) **PREDICT AREAS OF OCCURRENCE OF *Lonomia obliqua* WALKER 1855 (SATURNIIDAE, HEMILEUCINAE) IN THE PROVINCE OF MISIONES, ARGENTINA**

Marilia Favalesso (1), Milena G. Casafús (1), Ana T. Bittencourt Guimarães (2), Ma. Elisa Peichoto (3)
(1) Instituto Nacional de Medicina Tropical – CONICET. (2) Universidade Estadual do Ostes do Paraná. (3) Instituto Nacional de Medicina Tropical.

The *Lonomia obliqua* moth is a species of broad medical interest because its larvae are etiological agents of lonomism, a form of erucism which can lead the patient to death. Accidents have been common in Brazil since the end of the 80s, appearing in the province of Misiones (Argentina) by the beginning of this millennium. In order to find areas of high suitability for *L. obliqua* in the province of Misiones, *Species Distribution Modeling* algorithms were used: Bioclim, Gower, Mahalanobis, Maxent and SVM. For the model, 19 biogeoclimatic variables, the mean annual solar radiation and 9 soil variables were used. In order to avoid multicollinearity of the variables, a *Principal Component Analysis* was performed to create new orthogonal variables, resulting in seven new variables (cumulative variance> 90%). For the extraction of the niche information, 38 points of occurrence from Misiones and Brazil were selected and partitioned by the *jackknife n-1* technique. The background contemplated the geographic extension that refers to the biomes where the presences of *L. obliqua* were obtained: *Pampa*, *Atlantic forest*, *Caatinga* and *Cerrado*. From it, 10% of the information was sampled randomly to be considered as pseudo-absences in the model. The *Ensemble* technique was also applied from the frequency for the construction of a map that shows the appropriate areas in concordance among the models. The *Ensemble* took place from the threshold for the minimal presence of the species. The model was adequate (sensitivity=99%) and better than a null model ($p<0.05$). The final map shows the potential regions of occurrence of *L. obliqua* cut for the province of Misiones-AR. From the final map it is seen that the north and east of Misiones presents high suitability for the presence of *L. obliqua*. Therefore, public policy efforts need to be specially addressed in both regions in order to prevent cases of lonomism in this province.

Key words: venomous caterpillar, niche modelling, specie distribution, Brasil, Argentina.

(1692) **SUCCESSFUL MANAGEMENT OF PARASITIC INFECTIONS IN THE SOUTHERN GREEN PARROT SNAKE *Leptophis ahaetulla marginatus* (SERPENTES: COLUBRIDAE)**

María Lucía Bustos (1), Matías Nicolás Sánchez (1), Carlos Ariel López (1), Gladys Pamela Teibler (2), María Elisa Peichoto (1)
(1) Instituto Nacional de Medicina Tropical (INMeT), Ministerio de Salud de la Nación. (2) Facultad de Ciencias Veterinarias, Universidad Nacional del Nordeste (UNNE).

There are only a few examples of parasitism affecting snakes in Argentina, and there is a limited understanding of endoparasites in wild caught snakes. The current study summarizes the parasitic infections detected in some specimens of *Leptophis ahaetulla marginatus* (Lam) collected in the Iguazu National Park (Misiones, Argentina), in accordance with authorization from the National Park Administration (APN) N° 335, and transported to the serpentarium of the National Institute of Tropical Medicine (INMeT) (Argentina). Ecto and Endoparasite examinations were carried out by skin scrapping and parasitological analysis of fecal samples by both sedimentation and flotation concentration techniques. Four samples (each corresponding to different specimens) were positive for presence of Ascarididae-type eggs (Lam 1), Rhabdiasidae-type eggs and larvae (Lam 2), Eimeria-type oocysts (Lam 3) and Digenean trematode eggs (Lam 4). Treatments were done with administration of: 10% fenbendazole suspension orally at a dose of 40 mg/kg, which was repeated after 6 days (for Lam 1 and 2); Trimethoprim/Sulfamethoxazole 25 mg/kg IM per day for 2 days and then one dose every two days for another 10 days (for Lam 3); Praziquantel orally at a dose of 7.5 mg/kg which was repeated after 15 days (for Lam 4). Fecal sample re-examinations were carried out after fifteen days of each treatment and they were found negative. Thus, this study provides relevant information about the parasitic fauna of wild specimens of a colubrid snake commonly found in northeastern Argentina, and gives insight into their corresponding treatment.

Keywords: Antiparasitic drugs, Endoparasites, Colubrid snake.

(687) **A CASPASE-INDEPENDENT PATHWAY IS INVOLVED IN MANGANESE-INDUCED APOPTOSIS IN BV-2 MICROGLIAL CELLS**

Soledad Porte Alcon, Roxana Gorojod, Agustina Alaimo, Mónica Kotler
Dpto Química Biológica, FCEN-UBA, IQUIBICEN-CONICET.

Manganese (Mn) overexposure causes a neurodegenerative disease known as Manganism. Several mechanisms have been implicated in Mn neurotoxicity including oxidative stress (OS) and inflammation. Microglia are activated in response to Mn and release various pro-inflammatory cytokines (IL-1β, IL-6 and TNF-α) and soluble factors, includingreactive oxygen and nitrogen species, which could promote neuronal death. However, little is known about Mn toxicity in microglia. We previously demonstrated that BV-2 microglial cells exposed to Mn (250 and750*μ*M; 24h) exhibit apoptotic features such as the activation of caspases involved in intrinsic and extrinsic cell death pathways. In addition, we reported that OS and lisosomal membrane permeabilization were involved in cell death. In the present work we continue unraveling the molecular pathways involved in Mn-induced toxicity in BV-2 cells.To determine the role of caspases, we performed cell viability assays (MTT) in the presence ofcaspase-8(Ac-LEHD-CMK), caspase-9 (Z-IETD-FMK) and pancaspase (Z-VAD-FMK) inhibitors. Interestingly, these inhibitors did not prevent Mn-induced cell death. In accordance, Mn increased a 68% ($p<0.001$) the nuclear translocation of AIF (WB).AnnexinV/PI analysis (FACS) showed that 51% of Mn-exposed cells were necrotic/late apoptotic ($p<0.001$). In this context, Necrostatin-1, an inhibitor of RIP1-dependentnecroptosis had no effect on Mn-induced cell death (MTT). On the other hand, we demonstrated that Mn induces DNA damaged revealed by increased expression levels of γH2Ax in nuclear fractions ($p<0.001$)(WB) and a 30% reduction in procaspase-2 levels ($p<0.01$).In summary, our results suggest that Mn exerts genotoxicity in BV2 cells. In this scenario, caspases could be activated to induce microglial activation while cell death is governed by a caspase-independent apoptotic mechanism.

The hypothalamic-neurohypophysial system has recently emerged as an important component of neuroendocrine–immune network, wherein the oxytocin (OXT)-secreting system, consisting of OXT magnocellular neurons in the paraventricular (PVN) and supraoptic nuclei (SON), plays an essential role. Lipopolysaccharide (LPS) administration activates the immune response and neurohypophysial hormones secretion. Our previous studies provided direct evidence for the enhancement of OXT release from hypothalamus during LPS-induced inflammation (J Neuroimmunol 221, 2010). Moreover, a cross-talk between OXT neurons and adjacent astrocytes determines the neuroimmunoendocrine final response. These findings reveal that OXTnergic system could be a relevant component of the modulatory network of immune processes. Our objective was to evaluate the possible anti-inflammatory role of OXT during an LPS challenge. Adult male Sprague-Dawley rats were treated with OXT via sc (10, 100 and 1000 mg/kg) or via icv (1mg/kg) or vehicle (CTROL) and after 15 min were injected with LPS (5mg/kg, ip). Additionally, microglial tumoral cells (BV-2) and primary astrocytes cultures were pre-treated with OXT (0.1, 1, and 10 μM) for 15 min and then incubated with LPS (500 ng/ml) for 30 and 60 min. TNF-α concentration in plasma and medium were determined by ELISA. ANOVA analysis indicated OXT immunomarcation of magnocellular neurons at PVN and SON was increased by LPS, suggesting the activation of these neurons with an accumulation of OXT vesicles in the hypothalamus. OXT (100 and 1000 mg/kg, sc) significantly ($P<0.05$) prevented LPS increased in TNF-α plasma levels. Conversely, OXT (1ug/kg, icv) centrally injected did not modify TNF-α plasma levels. However, pre-treatment of BV-2 microglial cells and primary astrocytes cultures with OXT significantly ($P<0.05$) prevented LPS-increased TNF-α levels in culture media. In conclusion, our data suggest an anti-inflammatory effect of OXT during an immune challenge.

(194) **CEREBELLAR MICROVASCULAR AND GLIAL ALTERATIONS DURING THE ENCEPHALOPATHY PRODUCED BY SHIGA TOXIN 2 (Stx2) FROM ENTEROHEMORRHAGIC *Escherichia coli* (EHEC)**

Vanina Giselle Velardo (1), Jan Marcos Kalinski (1), Clara Valentina Berdasco (1), Adriana Cangelosi (2), Patricia Geoghegan (2), Jorge Goldstein (1)

(1) Instituto de Fisiología y Biofísica "Houssay", IFIBIO, Facultad de Medicina, Conicet/UBA. (2) Centro Nacional de Control de Calidad de Biológicos (CNCCB), ANLIS, "Dr. Carlos G. Malbrán".

Hemolytic uremic syndrome is a triad of events that includes thrombocytopenia, microangiopathic hemolytic anemia and acute renal failure caused by Stx2 from enterohemorrhagic *Escherichia coli* (EHEC). It has been observed that Stx2 produces deficits of coordination and equilibrium in patients which suggest cerebellar impairment. The aims of this study were to determine whether Stx2: i. passed through the blood-cerebrospinal fluid barrier into cerebellar parenchyma and ii. caused cell damage. Male NIH mice (n=4) were injected intravenously with 1ηg of Stx2 per mice or 100 μl of saline solution (control group). After 4 days of treatment, fixed brains were subjected to immunofluorescence with lectins to determine the microvasculature profile, anti-Stx2 to identify the presence of the toxin in cerebellum tissue, and anti-GFAP (Glial Fibrillary Acidic Protein) to determine reactive astrocytes. Micrographs were taken in a confocal microscope and obtained images were analyzed through the software ImageJ. Stx2 was found in parenchyma cells of the cerebellum. The statistical results analyzed by Student's t-test showed that Stx2 decreased the area occupied by the microvasculature (18.78 ±0.67 μm^2 control versus 9.37 ±0.42 μm^2 Stx2) and increased the expression levels of GFAP in comparison to the control (20.32 ±0.41 AU control versus 29.05 ±0.48 AU Stx2, in IOD) $p<0.01$. As shown in lectin histofluorescence binding essay this study demonstrated that, after 4 days of treatment, Stx2 was able to reach the Purkinje and granular cerebellar layers and damaged the endothelial cells. Furthermore, the astrocyte reaction is an evidence of cerebellar parenchyma injury, probably through Gb3 neuronal receptor or tissular mediators.

Key Words: Astrocyte, Microvasculature, Damage, Purkinje, neurons

(400) **DAMAGE ASSOCIATED PROTEIN HMGB1 PLAY A KEY ROLE IN THE NEUROINFLAMMATION AND NEURODEGENERATION THAT FOLLOWS STATUS EPILEPTICUS**

Jerónimo Auzmendi, Paula Sarchi, Alberto Javier Ramos

IBCN

High-mobility group box-1 (HMGB1) is a DAMP released after brain injury that activates local microglia and astrocytes but also behaves as long-range cytokine acting on the professional immune organs. Activated (reactive) astrocytes, can secrete molecules such as Thrombospondin-1 (TSP-1) that induce excitatory synapses and thus could have a major role in the altered excitatory/inhibitory balance that is the biological substrate of epileptogenesis. However, HMGB1 role in epileptogenesis is still unclear. For that purpose, status epilepticus (SE) was induced on 300 g Wistar rats by lithium chloride plus pilocarpine treatment (127 mg/kg and 30 mg/kg respectively) and stopped with 20 mg/kg diazepam after 20 min of SE. Then, we blocked the signalling of HMGB-1 applying glycyrrhizin (GLY) 333 mg/kg (i.p) twice a day for four days. To evaluate the expression of synaptogenic molecule TSP-1, i*n vitro* studies were performed on glial mix cultures or enriched astrocytes cultures. Both types of culture were stimulated with recombinant HMGB-1 (500 ng/ml) and TSP-1 expression was determined by immunofluorescence. *In vivo*, we found that GLY treatment significantly reduced both reactive gliosis and neuronal death in cortex and hippocampus (one-way ANOVA $p<0.05$). Furthermore, GLY treatment also reduced the typical SE-induced infarct zone in the pyriform cortex by proximately 10 times (t-test $p< 0.0001$) and 25% of rats were infarct free. *In vitro* studies showed that astrocytes as well as microglia stimulated with HMGB-1 expressed TSP-1, on a microglia-dependent manner (one-way ANOVA $p<0.01$). We conclude that HMGB-1 may play a main role in the mechanism of the epileptogenesis by promoting the microglial and astroglial activation and their subsequent expression of TSP-I that could be responsible for altered the excitatory/inhibitory synaptic balance in the epileptic brain. Hippocampal neuropathology is a recognized feature of the spontaneously hypertensive rat (SHR). Previous studies have found that SHR present abnormalities in the hippocampus consisting of decreased cell proliferation in the dentate gyrus (DG), astroglial and microglial reactivity and decreased neuronal density in the hilus of the DG. These abnormalities are reversed by exogenous administration of estradiol, an active neuroprotective and hypotensive factor. We recently demonstrate that both types of estradiol classical receptors (ERα and ERβ) are involved in the neuroprotective action of estradiol. GPR30 is a membrane estradiol receptor which is expressed in hippocampus and it is known to be involved in neuroprotective actions. To elucidate if this receptor is involved in the protective effects in SHR we used the GPR30 agonist G1 given s.c. during 2 weeks at 150 μg/kg/day to 4 month old male SHR. We measured the expression of GFAP and IBA1 in the CA1 and hilus of the hippocampus by immunocytochemistry. We found that hypertensive animals have increased expression of GFAP+ astrocytes in both regions of the hippocampus ($p<0.01$) and treatment with G1 reduced the number of positive astrocytes ($p<0.05$). The number of IBA1+ microglia is increased in hippocampal CA1 area of SHR and G1 treatment

reduced this number (p<0.001).

These data indicate that GPR30 membrane estradiol receptor is involved in the reduction of astroglial and microglial reactivity. Given the undesirable effects due to estradiol treatment, much effort is made to look for alternative treatments that mimic estradiol neuroprotective actions avoiding the undesirable effects. These effects of G1 open an interesting possibility in this direction.

Hypertension-Neuroprotection-Estradiol Receptor

(530) **MIGRATION OF RETINA GLIAL CELLS REQUIRES THE SYNTHESIS OF CERAMIDE-1-PHOSPHATE**

Marcela Vera, Facundo Prado Spalm, María Victoria Simón, Nora Rotstein

Instituto de Investigaciones Bioquímicas de Bahía Blanca INIBIBB; Departamento de Biología Bioquímica y Farmacia, Universidad Nacional del Sur UNS.

Retina proliferative diseases are major causes of visual dysfunction. Müller glial cells (MGC),the major glial cell type in the retina, and retinal pigment epithelial (RPE) cells play a key role in these diseases. Injuries to the retina exacerbate their proliferation and migration that contribute to visual loss. The molecular cues involved in these processes are still ill defined. We demonstrated that a sphingolipid, sphingosine-1-phosphate (S1P), promotes glial migration. We now investigated whether ceramide-1-phosphate (C1P), which controls proliferation and migration in certain cell types,participates in glial and RPE cell migration.

We evaluated migration in primary glial cultures,prepared from newborn rat retinas, and in a RPE cell line (ARPE19), by the wound repair assay. Addition of 10 μM C1P doubled MGC migration. To investigate whether C1P synthesis was required forglial migration, we first established by PCR that MGC expressed ceramide kinase (CerK), the enzyme catalyzing C1P synthesis. NVP231, a CerK inhibitor, completely prevented glial migration, which was not restored by C1P addition. Noteworthy, ARPE19 cell migration was also inhibited by NVP231. We then investigated the signaling pathways involved in C1P effect. Inhibiting the PI3K and the ERK/MAPK pathways, with LY294002 and U0126, respectively, decreased glial migration, both in control and C1P-treated cultures. SP6000, a Jun K inhibitor, also blocked C1P-induced glial migration. C1P activates a cytoplasmic phospholipase A2 (cPLA2) in different cell types. Pre-treatment with ATK, a cPLA2 inhibitor, markedly reduced glial migration in control and C1P-treated cultures.

These results show that C1P promotesglial migration through the activation of cPLA2 and the Jun K, the PI3K and the ERK/MAPK pathways. They also imply that exogenous C1P promotes C1P endogenous synthesis to stimulate glial and epithelial cell migration, supporting C1P as a central cue for regulating migration in these cells.

(492) **NEUROINFLAMATORY-RELATED PROCESES AND COGNITIVE DEFITIS INDUCED BY AN ANMIMAL MODEL OF TRAUMATIC BRAIN INJURY: CHARACTERIZATION OF TEMPORAL COURSE**.

Marisa Ghersi, Agustín Montivero, María Florencia Constantin, Elizabeth Heer, Mariela F. Perez

IFEC-CONICET, Dpto. de Farmacología, Facultad de Ciencias Químicas, UNC.

Brain damage caused by acute trauma (TBI) is associated with high morbidity and mortality. In Argentina is considered the leading cause of disability in children and young adults.TBI is a complex disorder caused by primary and secondary injury mechanisms. Primary mechanisms are the result of mechanical damage. Secondary injury progresses (SI) begin after minutes, or even months after the initial trauma as a result of neurochemical, metabolic and cellular changes. These secondary events are believed to underlie the development of many neurological deficits.The aim of the present investigation is to elucidate the temporal course of SI related to neuroinflamation and cognitive deficits induced in an animal model of TBI, to find a suitable window time for pharmacological intervention. For this purpose we used a closed head impact controlled by weight dropas an animal model of TBI. Animals were evaluated clinically immediately post TBI (hart and respiratory rate and apnea), and 60 min, 24 h and 7 days after TBI, were sacrificed to measure glia inflammation labeling GFAP (astrocytes) and CD11b (microglia) by immunohistochemistry (IHC). Also, Barnes Maze was performed 24 h post TBI to evaluate spatial memory. Our results showed increased glial activation profiles in hippocampus at 60 min and 24 h, returning to SHAM values at 7 days post TBI. No differences between SHAM and TBI groups were observed in behavioral performance. IHC and behavioral data were analyzed by one way ANOVA or t-test respectively. In conclusion, our data suggest that the neuroinflamation observed early after TBI did not affect a hippocampal-dependent memory acquisition and retrieval, at the timeevaluated. As described by other authors, these deficits could be observed long term after TBI as a consequence of early neuroinflamation. Further studies need to be performed to evaluate this possibility and to complete the neuroinflamatory profile.

Keywords: Traumatic brain injury (TBI), neuroinflamation, spatial memory, glia.

(228) **PARTICIPATION OF THE MICROGLIA IN HIPPOCAMPAL DYSFUNCTION BY SHIGA TOXIN 2 (STX2) FROM ENTEROHEMORRHAGIC *Escherichia coli* (EHEC) PRODUCING HEMOLYTIC UREMIC SYNDROME**

Clara Valentina Berdasco (1), María Victoria Rosato-Siri (2), Jorge Goldstein (1)

Instituto de Fisiología y Biofísica "Houssay", IFIBIO, Facultad de Medicina, Conicet/UBA. (2) Departamento de Química Biológica, Facultad de Farmacia y Bioquímica. IQUIFIB-CONICET, Universidad de Buenos Aires

Stx2 causes bloody colitis, HUS and neurological dysfunctions. Hippocampal cognitive deterioration is observed. EHEC secretes Stx2 and releases LPS. The aim was to determine whether sub-lethal Stx2 (S), LPS (L) or Stx2 co-administered with LPS (S+L) altered the hippocampal neurovascular unit by microglial activation. Male NIH mice (n=4) were injected iv. with: saline (control, C); 800ηg of L; 1ηg of S or 1ηg of S with 800ηg of L (S+L). Fixed brains were subjected to immunofluorescence with lectins to determine the microvasculature profile, anti-GFAP, anti-NeuN and anti-Iba1 to identify reactive astrocytes, neuronal damage and the microglial state respectively from 2 to 20 days post injection. Primary microglial cultures were incubated with either DMEM (C), 1 and 100 ηg/ml of S, or 1 and 100 ηg/ml of S with 800 mg/ml of L (S+L), following heat shock incubation to test microglial activation. Anti-Iba1 and anti-Stx2 immunofluorescences were used to identify microglia cells and intracellular Stx2 respectively. The deepest hippocampal deterioration was observed after 2 days of S+L treatment. S+L and S treatments resulted to decrease the area occupied by microvasculature (7.35 ±0.25 C; 5.25 ±0.38 L; 2.75 ±0.15 S; 1.4 ±0.21 S+L), increased the expression levels of GFAP (0.19 ±0.02 C; 0.36 ±0.04 L; 0.52 ±0.02 S; 0.60 ±0.02 S+L) and decreased the thickness of pyramidal layer (59 ±1.3 C; 48 ±1.44 L; 42 ±1.15 S; 36 ±1.5 S+L) $p<0.05$. The maximal expression of Iba1 were found at 100 ηg/ml of S co-incubated with 800 mg/ml of L, and at 100 ηg/ml of S on microglial primary culture cells: 74 ±2.31 C; 85 ±1.8 L; 143 ±2.21 S; 189 ±2.57 S+L; accordingly, Stx2 was found maximally intracellular in the microglia in S+L: 71 ±1.63 S+L, 34 ±2.81 S, in IOD, $p<0.05$. Stx2 damaged the microvasculature, affected the astrocytic state and caused neurodegeneration. LPS aggravated Stx2 deleterious effects. The microglia, being reactive to Stx2, could play a pivotal role in inflammatory mechanisms.

Keywords: microglial cultures, microvasculature, astrocyte, LPS

(627) **TOLL-LIKE RECEPTORS IN THE PROPAGATION OF REACTIVE GLIOSIS IN THE INJURED BRAIN**

Maria Belen Cieri, Vanesa Cadena, Gerardo Rosciszewski, Jeronimo Auzmendi, Alberto Javier Ramos

Instituto de Biologia Celular y Neurociencias. Prof. De Robertis, IBCN, UBA-CONICET.

Following brain injury astrocytes undergo phenotypic changes collectively known as reactive gliosis. Detrimental effects of reactive gliosis for neuronal survival occur when astrocytes polarize to the

A2 phenotype expressing proinflammatory genes. We previously shown that Toll-like receptor 4 (TLR4) and NF-kB signaling are required the A2 polarization (Rosciszewski et al., 2017). However, it is still unknown how reactive gliosis propagates to reach distal brain regions. It is proposed that damage associated proteins released by dying neurons acting on TLR are probably involved. To address this question, we here performed a penetrating traumatic brain injury in rodents by stab wound (2 mm lateral; 2 mm Bregma, 2 mm depth) in wild type, TLR4KO and TLR2KO animals. In vitro, we studied the downstream signaling pathways involved in the reactive gliosis propagation by using the scratch wound healing assay. Stab-wounded animals showed a gradient of reactive gliosis analyzed by GFAP immunostaining morphometry that was present at 3-7 days post-injury (3-7 DPI), and then at 14 DPI, the gradient was lost and reactive gliosis propagated by the entire hemisphere. At 7 DPI, the TLR4KO, but not TLR2KO, animals showed a decreased gradient of reactive gliosis ($p<0.05$, two way ANOVA). In vitro, scratch wounds also produced a gradient of reactive gliosis either in purified astrocytic culture or in mixed microglial-astroglial culture. In astroglial-enriched cultures, but not in mixed culture, the gradient was prevented by the NFkB chemical blocker BAY117082 (10 μM), by Ca2+ chelating agent EGTA (20 μM) or by the gap-junction blocker MFA (100 μM). On the other hand, the exposure to the TLR4 agonist LPS exacerbated the reactive gliosis gradient. Taken together these results show that reactive gliosis propagation is a phenomenon that involves both astrocytes and microglia and seems to require TLR4. Supported by PICT 2015-1451; UBACYT.

(1251) **ALCOHOL HANGOVER INDUCES ALTERATIONS IN MITOCHONDRIAL FUNCTION AND NITRIC OXIDE METABOLISM IN MOUSE BRAIN CORTEX SYNAPTOSOMES AND NON-SYNAPTIC MITOCHONDRIA**

Analia Graciela Karadayian, Analia Czerniczyniec, Paulina Lombardi, Silvia Lores Arnaiz

Instituto de Bioquímica y Medicina Molecular. Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires

Alcohol hangover (AH) is the transient state that occurs after acute ethanol consumption and begins when blood alcohol concentration is zero. The aim of the present work was to study mitochondrial bioenergetics and NO metabolism at the beginning of AH in brain cortex synaptosomes (S) and in non-synaptic mitochondria (NSm). Swiss male mice were treated with a single i.p. injection of saline (control group) or ethanol (3.8 g/kg; AH group) and the biochemical assays were performed at AH onset. Results showed a significant decrease in respiratory function in both subcellular fractions ($p<0.05$). The enzymatic activity of complex I-III and II-III was 21% and 33% decreased respectively in S while no changes were observed in NSm. Complex IV activity was 48% and 42% decreased in S and NSm respectively. Transmembrane potential was 20% decreased in S and 15% decreased in NSm ($p<0.05$). The expression of the uncoupling protein UCP-2 was 49% increased in S and 31% decreased in NSm. ATP basal content was 51% and 64% reduced in S and NSm respectively ($p<0.01$). Moreover, ATP production was 26% decreased in S. In NSm, malate-glutamate ATP production was 28% decreased while a 37% decrease was observed in succinate ATP production. On the other hand, NOS expression was 19% and 10% decreased in S and NSm respectively. Together with this, NOS activity was 36% decreased in S and remained unchanged in NSm. In line with this, total content of NO was 30% decreased in S while no changes were observed in NSm. Related to NO metabolism, the expression of the post-synaptic density 95 protein was found to be 16% decreased due to AH in S fractions ($p<0.05$). It could be concluded that AH induced a significant mitochondrial dysfunction and alterations in NO metabolism. AH-induced oxidative stress previously observed in S could be associated with the induction of UCP-2, which would exert a regulatory action on oxygen radical generation and mitochondrial depolarization.

Keywords: alcohol hangover, synaptosomes, mitochondria, nitric oxide

(1360) **BRAIN ANGIOTENSIN II INVOLVEMENT IN THE DEVELOPMENT OF LONG LASTING AMPHETAMINE-INDUCED NEUROINFLAMATION RESPONSES IN PRELIMBIC PREFRONTAL CORTEX RELATED TO WORKING MEMORY DEFICIT**

Osvaldo Martin Basmadjain (1), Samanta Armonelli (1), Natalia Andrea Marchese (1), Victoria Belén Occhieppo (1), Gustavo Baiardi (2), Claudia Bregonzio (1)

(1) IFEC CONICET UNC. (2) IIBYT CONICET UNC.

Amphetamine (Amph) promotes enduring alteration over neural circuits that can be observed long after. These persistent neuroadaptations also extend to the development of central inflammatory related pathologies, such as glial activation and vascular damage. Angiotensin II, through AT_1 receptors (AT_1-R) activation, modulates dopamine synthesis and release over limbic areas, and participates in reward and learning responses. Moreover, its activity has a greater extend as it modulates several stages of the inflammatory process in neurons and glia. This work aimed to study AT_1-R involvement in neuroinflammatory alterations induced by Amph repeated exposure. Neuroinflammation was evaluated by astrocyte and microglia reactivity at different brain areas, whereas working memory was asses to identify cortical alterations.

Male Wistar rats (250-300g) were used. To study the participation of AT_1-R in long–term Amph effects, the AT_1-R blocker Candesartan (CV 3mg/kg p.o.) was administered for 5 days prior the daily Amph administration (2.5mg/kg i.p x 5 days). On weeks 1 or 3 of Amph withdrawal working memory performance was evaluated using Y-maze test, 24h later the animals were perfused and the brains prepared for GFAP and CD11b immunohistochemistry. The results were analyzed using 2-way ANOVA followed by Bonferroni test. It was found that, at both times analyzed, Amph increased GFAP and CD11B expression only at prelimbic prefrontal cortex concomitant with working memory deficit. These structural and functional alterations were prevented by AT_1-R blockade. We conclude that AT_1-R activation is a key mediator in the development of Amph-induced neuroinflammatory responses underpinning prelimbic prefrontal functional alterations.

(1876) **MORPHINE WITHDRAWAL SYNDROME: INVOLVEMENT OF THE CANNABINOID SYSTEM IN ADOLESCENT MALE AND FEMALE MICE**

Eliana Micaela Canero (1), Valeria Teresa Pedrón (1), Andrés Pablo Varani (1), Amira Jazmín Aon (1), Graciela Noemí Valerio (1,2)

(1) CONICET - Universidad de Buenos Aires. Instituto de Investigaciones Farmacológicas (ININFA). Buenos Aires, Argentina. (2)Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica: Cátedra de Farmacología. Buenos Aires, Argentina.

Previous studies suggest the existence of an interaction between the opioid and cannabinoid systems during morphine (MOR) withdrawal syndrome. CB_1 cannabinoid receptor deficient (CB1 KO) mice showed lower intensity in naloxone (NAL)-precipitated MOR withdrawal syndrome than their wild-type (WT) littermates. On the other hand, previous studies from our laboratory have shown sex differences in the expression of NAL-precipitated MOR withdrawal syndrome in WT Swiss Webster Albino mice. The aim of the present study was: I) to explore the presence of sex differences in the expression of MOR withdrawal syndrome in CB1 KO mice and their WT littermates, II) to evaluate the c-Fos expression of certain brain areas in CB1 KO and WT mice during MOR withdrawal syndrome.

CB1 KO and WT mice from day 25 postnatal forward, were treated for 9 days with MOR (2 mg/kg, i.p.) or saline (SAL) twice daily. On the tenth day, animals received NAL (6 mg/kg, i.p.) or SAL 60 min after the last injection in order to precipitate the withdrawal syndrome, and immediately after somatic sings were counted during 30 minutes. At the end of the behavioral test, mice were transcardially perfused with 4% paraformaldehyde solution. Brains were removed

and postfixed for 2 h in the same fixative, and coronal frozen sections were made at 30 µm on a freezing microtome to perform the c-Fos immunohistochemistry.

No sex differences were observed during MOR abstinence syndrome in any of the genotypes (WT and CB_1 KO mice). In addition, It was observed an increase in the number of c-Fos positive nuclei in the Nucleus Accumbens Core, Habenula Lateral ($p<0.01$) and Caudate Putamen ($p<0.05$) of WT, but not in CB1 KO mice during MOR withdrawal syndrome.

These results suggest that the lower intensity previously observed during NAL-precipitated MOR withdrawal syndrome in mice lacking CB_1 receptors, could be related to the lack of changes in c-Fos expression.

(1260) **THE COMBINED ADMINISTRATION OF ALCOHOL AND TAURINE INDUCES MITOCHONDRIAL DYSFUNCTION AT THE BEGINNING OF ALCOHOL HANGOVER IN MOUSE BRAIN CORTEX**

Analia Graciela Karadayian (1), Analia Czerniczyniec (1), Silvia Carbone (2), Rodolfo Angel Cutrera (2), Silvia Lores Arnaiz (1)
(1) Instituto de Bioquímica y Medicina Molecular. Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, (2) Instituto de Fisiología y Biofísica Bernardo Houssay. Facultad de Medicina, Universidad de Buenos Aires

The combination of alcohol intake and energy drinks is often used as a possible attenuator for hangover symptoms. Alcohol hangover (AH) is the transient state that occurs after an acute ethanol consumption episode and begins when blood alcohol concentration is zero. Particularly, taurine is one of the major components of energy drinks. Therefore, the aim of this work was to evaluate if the combined administration of taurine and alcohol induces brain cortex mitochondrial dysfunction, through determinations of oxygen consumption, mitochondrial membrane potential and hydrogen peroxide production at the beginning of alcohol hangover. Swiss male mice were divided into four experimental groups: control (saline i.p.), taurine (70 mg/kg i.p.), alcohol (3.8 g/kg i.p.) and taurine-alcohol. Data were analyzed by one-way ANOVA. Alcohol hangover group showed 28% and 20% decreases in malate-glutamate state 3 respiration and respiratory control respectively ($p<0.05$). In taurine-treated animals, a 24% decrease was observed in malate-glutamate state 4 respiratory rate, leading to a 24% increase in respiratory control ($p<0.05$). The combined administration of alcohol and taurine significantly reduced state 4 and state 3 respiratory rates in 35% and 42% respectively at the hangover onset ($p<0.05$). Mitochondrial membrane potential was 11% and 20% decreased in alcohol and taurine-treated groups respectively ($p<0.05$). Hydrogen peroxide production was increased by 30-35% in alcohol, taurine and alcohol-taurine groups using malate-glutamate as substrates ($p<0.01$). Moreover, hydrogen peroxide production using succinate as substrate was 54%, 100% and 30% increased in alcohol, taurine and alcohol-taurine groups respectively. Altogether, the results allow concluding that the combined administration of alcohol and taurine not only did not prevent mitochondrial dysfunction induced by alcohol hangover but also aggravate it and induced active oxygen species generation.

Keywords: alcohol hangover, taurine, mitochondria, oxidative stress

(1897) **BRIEF ETHANOL DOSES MODIFIES 5HT LEVELS AT RAPHE OBSCURUS IN NEONATE RATS**

Ana Fabiola Macchione (1,2) Veronica Trujillo (1), Agustin Anastasia (1), Juan Carlos Molina (1,2)
(1) INIMEC-CONICET-UNC. (2) FAC. PSICOLOGIA, UNC.

Ethanol is the most commonly abused substance that impacts the humans during early ontogeny (gestation and lactation). Ethanol effects include alterations in brain development, learning and memory, cognitive abilities and neurovegetative functions such as breathing. A major target of ethanol in the central nervous system is the serotonin (5HT) neurons involved on the respiratory regulation. Preclinical studies employing chronic and severe ethanol consumption models during pregnancy and lactation, showed a decrease in the number of 5HTneurons and 5HT levels in the raphe system. However, the status of the serotonergic system in animal models with moderate and neonatal ethanol exposure are understudied. Thus, the main goal of this study was to evaluate 5HT levels in the raphe obscurus (ROb) nucleus in neonate rats, as a function of moderate ethanol or vehicle exposure (2.0 or 0.0g/kg, intragastrically) at postnatal days (PD) 3, 5 and 7. At PD 9, pups were intoxicated or vehicle administrated. Ninety minutes after, all pups were sacrificed and 5HT levels were immunodetected at the ROb. A significant reduction of 5HT levels was observed in pups exposed to ethanol for the first time at PD 9 and vehicle-pretreated at PDs 3, 5 & 7. Interestingly, a similar decrease in 5HT levels was also found in ethanol-pretreated pups evaluated under sobriety at PD 9. These results indicate a profound effect of ethanol upon on 5HT levels at ROb, nucleus specifically involved in breathing regulation. These data indicate that perinatal ethanol exposure is enough to alter 5HT levels in the Rob. These results became important when associating the function of the ROb on respiratory response and breathing disturbances commonly observed in neonate rats and humans, such as Sudden Infant Death Syndrome.

(1772) **IMPAIRMENT OF NITRIC OXIDE METABOLISM AT CENTRAL SYNAPSES BY LEVOCABASTINE, AN ANTAGONIST FOR NEUROTENSINERGIC NTS2 RECEPTOR**

Alicia Gutnisky (1), Analía G Karadayian (2), Silvia Lores Arnaiz (2), Georgina Rodríguez De Lores Arnaiz (1)

Neurotensin is able to modulate ionic gradient equilibria through neuronal membranes because it inhibits the activity of the sodium pump. Some properties of Na^+, K^+-ATPase are modified by the administration of L-NAME (Nω-nitro-L-arginine methyl ester), an inhibitor of nitric oxide synthase (NOS), and by levocabastine, an antagonist for neurotensinergic NTS2 receptor. In the search of a relationship between the activity of neurotensin NTS2 receptor and nitric oxide (NO) synthesis, levocabastine was administered to rats and the activity and expression of NOS were evaluated. Wistar rats injected (i.p.) with levocabastine (50 µg/kg) or saline solution (controls) were decapitated 30 min, 18 or 36 hours later. Cerebral cortices were processed by differential and sucrose gradient centrifugation to obtain synaptosomal membrane fractions. Nitric oxide production by NOS was measured following the oxidation of oxyhemoglobin to methemoglobin at 577-591 nm in a double-beam dual-wavelength spectrophotometer. Neuronal and inducible NOS expression were evaluated by Western blot assays. In synaptosomal membrane fractions NOS activity decreased 46% and 74% at 30 min and 18 hours after levocabastine administration ($p<0.05$). These changes were reversible in time. *In vitro* incubation of control synaptosomal membranes with 1 µM levocabastine also decreased the activity of NOS. At 30 min and 18 hours after levocabastine administration the expression of neuronal NOS protein decreased by 18% and 56% ($p<0.05$). These changes did not reverse in time. Concomitantly, an enhancement of inducible NOS expression was recorded after levocabastine treatment. Altogether, the results allow us to suggest that the NTS2 antagonist levocabastine markedly modified NOS activity and expression at CNS synapses, showing a possible interrelationship between the activities of neurotensinergic and nitrergic systems.

Keywords: cerebral cortex, nitric oxide synthase, synaptosomal membranes, neurotensin receptor, levocabastine

(951) **KETAMINE EFFECT ON CALCIUM CONCENTRATIONS AND CELL METABOLISM IN PC12 CELLS**

Maria Macarena Ruffinelli (1), Silvia Lores Arnaiz (2), Federico Orgambide (2), Juanita Bustamante (1)
(1) Centro de Altos Estudios en Ciencias Humanas y de la

Salud (CAECIHS), Universidad Abierta Interamericana, Buenos Aires, Argentina, (2) Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Cátedra de Fisicoquímica, Buenos Aires, Argentina.

Ketamine an inhibitor of NMDAR; has coupled ion channels highly permeable to calcium ions. Changes in intracellular [Ca^{2+}], are essential for neurophysiological processes, being indicators of physiological functions in neurons. This work evaluates the changes in [Ca^{2+}] induced by depolarization after 24 h exposure of PC12 cells to 100, 500 and 1000 μM ketamine. Ketamine effects on mitochondrial membrane potential ($\Delta\Psi m$) and nitric oxide (NO) levels were also analyzed. Methods using, Fluo-4 AM, epifluorescent microscopy, multiple-label counter and flow cytometry were used. Micrographies quantification showed that ketamine 100 μM and 500 μM decreased the number of positive fluorescent cells. Meanwhile, 1000 μM ketamine showed highest fluorescence intensity, with highest values of positive fluorescent cells, being significantly different from control cells ($p<0.05$). The results obtained by multilabel counter Glo-Max®-Multi Detection System, and by flow cytometry showed that low ketamine concentrations decreased the calcium fluorescent signal significantly ($p<0.05$) as compared with control, and similar differences were recorded with both methods, being in absolute intracellular [Ca^{2+}], for control, 100 and 500 μM ketamine: 612±60 nM, 239±15 nM and 258±8 nM versus 567±33 nM, 99±10 and 118±7 nM respectively for each method. With 1000 μM ketamine the absolute intracellular [Ca^{2+}] was significantly ($p<0.05$) different as compared with control, being 1035±234 nM and 2175±443 nM for the two methods respectively, and was accompanied by cellular morphology typical of apoptotic death as predicted by SSC and FSC. Metabolic alterations, with a significant decrease ($p<0.05$) in $\Delta\Psi m$ and NO levels were observed after all ketamine doses as compared with control. We conclude that ketamine has consequences on intracellular calcium homeostasis, probably mediated by NMDARs blockage, inducing drastic changes in neurons.Keywords: ketamine, calcium concentration, mitochondria and nitric oxide.

(219) **EARLY ANALYSIS OF CEREBELLAR MICROVASCULAR AND ASTROCYTIC DAMAGE BY SHIGA TOXIN 2**

Jan Marcos Kalinski (1), Vanina Giselle Velardo (1), Clara Valentina Berdasco (1), Adriana Cangelosi (2), Patricia Geoghegan (2), Jorge Goldstein (1)
(1) Instituto de Fisiología y Biofísica “Houssay”, IFIBIO, Facultad de Medicina, Conicet/UBA. (2) Centro Nacional de Control de Calidad de Biológicos (CNCCB), ANLIS, “Dr. Carlos G. Malbrán”.

Shiga Toxin 2 (Stx2) is secreted by enterohaemorragic *Escherichia coli* (EHEC) and produces damage in several organs of the human body, including the cerebellum. The toxin travels through the blood stream and reaches several organs. The objective of this work is to observe whether Stx2 reaches the parenchyma of the cerebellum, and once in, if it can produce cell damage. For this work, NIH male mice were used. They were divided and injected intravenously in two groups (n=4): 1ηg/mice of Stx2 or saline solution (control group). Two days after the toxin was injected, they were sacrificed and their brains were fixed with PFA 4%. Then, their cerebellums were extracted and cut in slices 20μm thick. They were then subjected to histofluorescence technique with lectins to determine the microvasculature profile, anti-GFAP (glial fibrillary acidic protein) to identify reactive astrocytes and anti-Stx2 to identify immunopositive Stx2 cells. The group treated with Stx2 showed a decrease in the area occupied by the microvasculature (18.27 ±0.57 AU control and 5.77 ±0.2 AU Stx2, in IOD) along with an increase in the expression levels of GFAP (20.27 ±0.54 AU control and 36.35 ±0.95 AU Stx2, in IOD) $p<0,01$. The presence of Stx2 was detected in the Stx2 treated group and not in the control one, in the cerebellar cortex. This work proved that Stx2 damages the microvasculature of the cerebellum, and it produces astrocytary reaction (hiperthrophy and hyperplasia), which suggests a disruption on the Blood Brain Barrier of the cerebellum, and damages its parenchyma.

The non-proteic aminoacid BMAA is a cyanotoxin released by many cyanobacteria occurring in most dams and water resources around the world. Human chronic intake of this toxin has been linked with the development of neurodegenerative diseases, like Amyotrophic Lateral Sclerosis (ALS); Parkinson and Alzheimer Disease. Multiple studies have shown the effects of BMAA on live animals; however, its effects at the cellular or molecular levelsía are still mostly unknown. We here investigated the effects of BMAA on retinal amacrine and photoreceptor neurons and Muller glial cells (MGC) in vitro. We incubated pure neuronal cultures and mixed neuro-glial cultures obtained from newborn rat retinas, with 400 nM BMAA for 2 days. We then evaluated cell death and apoptosis by Propidium Iodide (PI) TUNEL assays, and DAPI staining. Mitochondrial activity was assessed by using Mitotracker and cytoskeleton integrity and axonal outgrowth were analyzed by immunocytochemical methods. In `pure neuronal cultures, BMAA increased the percentage of apoptotic amacrine and photoreceptor neurons, from 21.6% to 64.5% and from 29.3% to 65.7%, respectively, in controls and BMAA-treated cultures. Noteworthy, functional mitochondria decreased from 55% to 35% in photoreceptors but only slightly in amacrine neurons. In addition, BMAA treatment disrupted the organized assembly of tubulin in axons. BMAA addition to mixed neuro-glial cultures induced lamellipodia retraction and loss of mitochondrial membrane potential in MGC, but did not increase their cell death. Moreover, MGC partially prevented neuronal death.

These results suggest that BMAA induces subcellular changes in both neurons and glial cells, and markedly affects the viability of retinal neurons, confirming its threat to human health as a potential inducer of neurodegenerative damages.

Age-related macular degeneration (AMD) is a late-onset neurodegenerative retinal disease. Accumulated lipofuscin fluorophore A2E in retinal pigment epithelium (RPE) confers susceptibility to blue light-mediated damage, a risk factor for AMD. Cells have developed well-coordinated Mitochondrial Quality Control (MQC) mechanisms in order to limit mitochondrial injury induced by oxidative stress, ensure mitochondrial integrity and preserve cellular homeostasis. RPE dysfunction is a critical event in AMD. Thus, our study was designed to evaluate MQC status, including mitochondrial dynamics (fusion/fission) and mitophagy, under photooxidative damage conditions in RPE.

Light-emitting diodes irradiation (λ=445nm; 1.7mW/cm^2, 30min) significantly reduced the viability of both non-pigmented and 10 or 25µM A2E-containing human RPE cells (MTT assay: 52%, 46%, 31%, respectively) as well as increased mitochondrial anion superoxide production (MitoSOX). A2E (25μM), along with blue light, induced apoptosis measured by Annexin V/PI-flow cytometry (6-fold, $p<0.001$) and by procaspase-3 levels (38%, $p<0.01$). Photodamage produced fusion/fission imbalance towards mitochondrial network

fragmentation in non-pigmented cells (72%) and 25μM A2E-fed cells (92%) ($p<0.01$) which correlates with deregulation of mitochondria-shaping proteins levels. We detected a dramatic rise in the expression of fission protein DRP1 and a decrease in the mitochondrial fusion and anti-apoptotic OPA1 protein levels. Mitochondrial Δφm loss activates OMA1, a MQC protease that cleaves OPA1 to inhibit fusion and facilitate apoptosis. Particularly, A2E and blue light stimuli lead to OMA1 activation, revealed by it self-cleavage (5-fold, $p<0.01$). Finally, TOM20 and LC3 ICC analysis suggested an altered mitophagy. Our work reveals for the first time, that photodamage cause RPE dysfunction through MQC dysregulation which may contribute to AMD pathology. Moreover, the possibility to develop MQC-based therapies is outlined.

Cardiovascular system regulation would be crucial in pathological situations such as hypovolemia. The actions of thyroid hormones would be relevant during this condition considering its actions on cellular respiration and mitochondrial function. The aim of the present work was to examine the effect of thyroid state on rat heart mitochondria function during hypovolemia. Sprague-Dawley rats aged 2 months old treated with T3 (hyper, 20 μg/100 g body weight) or 0.02% methimazole (hypo, w/v) during 28 days. Hypovolemic state was induced by a loss of 20% of blood volume during 2 minutes. Hearts were removed for mitochondria isolation and determination of O2 uptake, enzyme activity of complex I and protein levels (mt-NOS, akt T and akt P). The malate-glutamate-supported state 3 respiration decreased and increased in hypo and Hyper rats. Hemorrhage did not change this parameter. Malate-glutamate-supported state 4 did not change. No differences in succinate-supported state 4 and 3 respiration were observed in all groups. Hypothyroidism increased nNOS protein levels. This protein levels did not change in Hyper animals. Withdrawal decreased and increased nNOS protein levels in hypo and Hyper rats, respectively. Hyper increased complex I activity and hemorrhage did not change this activity. No differences were observed between Eut and hypo rats. Hemorrhage only increased complex I activity in hypo group. Thyroid disorders increased aktT protein levels. Hemorrhage did not change this parameter. Hyper increased akt P protein levels meanwhile hemorrhage induced a decreased of this protein levels. In hypothyroidism the lowest NO production would be responsible for increasing cellular respiration and guaranteeing the supply of oxygen to the tissues. The opposite would happen in the hyperthyroid where high levels of NO try to decrease the oxygen consumption as in the euthyroid. Alterations of complex I activity as well as AKT pathway could mediate these effects.

(615) INFLUENCE OF NITRIC OXIDE AND ADRENERGIC STIMULATION ON THE CARDIOPROTECTION OF HYPOTHYROIDISM IN RAT HEARTS EXPOSED TO ISCHEMIA-REPERFUSION

María Inés Ragone, Lucía Clavelino, Matías Bayley, Alicia Elvira Consolini

Catedra de Farmacología Farmacia UNLP. CONICET

Hypothyroidism (HypoT) reduced the stunning in severe ischemia-reperfusion (I/R), but increased the sensitivity of mitochondria to the Ca^{2+} overload-induced dysfuntion (SAFE 2016). The aims of this work were to evaluate whether HypoT cardioprotection was due to nitric oxide (NO) release, and if it remains under more physiological adrenergic conditions. HypoT was induced by drinking methimazole (0.02%) for 15 days. Isolated hearts were perfused inside a calorimeter at 37°C to measure left ventricular pressure (LVP, in mmHg) and total heat rate (Ht, in $mW.g^{-1}$) during the exposition to severe I/R (30 min/ 45min R). The role of NO was evaluated by perfusing HypoT hearts with 30 μM L-NAME (to inhibit NO-synthase) before I/R. L-NAME improved the postischemic contractile recovery (PICR) to 84.8 ± 6.7% of initial pressure (Pi) ($p<0.05$ vs 53.9 ± 4.7% in non treated C-HypoT, n=8-5) and total muscle economy (Eco=P/Ht) to 4.0 ± 0.7 $mmHg.g.mW^{-1}$ (vs 2.8 ± 0.3 $mmHg.g.mW^{-1}$) without changing the diastolic tone. Nevertheless, the treatment with 10 μM nitroprussate (NO-donor) did not change the behavior of HypoT hearts on stunning (n=5). Moreover, perfusing 50 nM adrenaline before I/R reduced PICR to 20.0 ± 7.9 % of Pi (vs 53.9 ± 4.7 % in HypoT-C, $p<0.05$, n=6-5) and Eco to 1.2 ±0.6 $mmHg.g.mW^{-1}$ (vs 2.85 ± 0.3 in C-HypoT) with diastolic contracture (ΔLVEDP = 7.8 ± 0.5 mmHg, $p<0.05$ vs 0). Results suggest that: a) The NO release is not a cause of the cardioprotection of HypoT; b) There would be a threshold NO level to contribute to stunning; c) Under the physiological adrenergic conditions, HypoT was not cardioprotective as in its abscence, in agreement to that reported for clinical situations. *Grant: UNLP X-795*.

Continuous increase of glucocorticoids due to chronic activation of the pituitary axis is one of the consequences of chronic stress. The knowledge of its effects on plaque vulnerability markers and cardiovascular disease will help to elucidate different pathophysiological mechanisms. With this aim, we studied 15 C57BL/6j mice treated (TM) for 4 weeks with 35 μg/ml corticosterone and 15 control mice (CM). After euthanasia, heart, liver, adrenal glands, epididymal and intestinal adipose tissue (AT) were weighed. Serum lipid profile was evaluated. We performed a zymography of homogenized cardiac tissue and epididymal AT for measuring metalloprotease activity (MMPs). In isolated and isovolumetric hearts perfunded with Langendorff technique, we measured the left ventricle develop pressure (LVDP) and its response to ß adrenergic stimulus (Isoproterenol (iso) 1 μM). Results: At the end of treatment, adrenal gland weight was lower in TM (0.002 (0.0002) vs 0.003 (0.0004) gr, p=0.03). Weight gain was observed in TM vs CM (5.0 (1.5-9.5) vs 3.3 (2.0-7.0) gr, p=0.007), at expense of epididymal AT (0.73 (0.06) vs. 0.33 (0.04) g, $p<0.001$), without differences in heart, liver or abdominal AT (p= ns). In TM, a higher concentration of triglycerides (98 (12) vs 63 (7) mg/dl, p=0.02) and total cholesterol (116 (11) vs 78 (4) mg/dl, p=0.002) was observed. In TM increased activity of MMP-9 (0.48 (0.42-0.49) vs 0.37 (0.34-0.40) relative units (RU), p = 0.01) in heart tissue and lower MMP-2 activity (1.03 (0.04) vs 1.26 (0.07) RU, p=0.01) in AT was observed. Under baseline conditions, no differences in LVDP between TM and CT were observed. However, the response to Iso was lower in TM compared with CM (ΔLVDP: 14.9 vs 47.6 mmHg, p=0.02). Conclusions: After 4 weeks of treatment, we observed certain typical metabolic consequences effects of glucocorticoids. In addition, the impact on heart evidenced through an increase in MMP activity and a decrease in contractile reserve.

Keywords: Glucocorticoids; Metalloproteinases; Contractile reserve

(944) **REGULATION OF ANGIOGENESIS AND VASCULAR CALCIFICATION BY PROGESTERONE (Pg) AND ACETATE OF MEDROXYPROGESTERONE (MPA)**

Pablo Hernan Cutini, Adrian Esteban Campelo, Virginia Laura Massheimer

Instituto de Ciencias Biológicas y Biomédicas del Sur (INBIOSUR), Universidad Nacional del Sur (UNS), CONICET, Departamento de Biología, Bioquímica y Farmacia, Cátedra de Bioquímica Clínica II, Bahía Blanca, Argentina.

Hormone replacement therapy including natural or synthetic progestins is a therapeutic alternative to prevent cardiovascular disease, although the risk/benefit of its use is controversial. The cellular/molecular mechanisms of Pg and MPA displayed at vascular level are not fully understood. Vascular calcification (VCa) within atherosclerotic plaque involves vascular smooth muscle cells (VSMC) transdifferentiation to osteogenic lineage. Furthermore, angiogenesis represents a survival option for damaged tissue. The aim of this work was to investigate the role of Pg and MPA on: a) metabolic/phenotypic changes of VSMC in a pro-calcifying environment, and b) angiogenesis (capillary tube formation and VEGF synthesis). VSMC were cultured in DMEM for 21 days with 4 mM $CaCl_2$ and 10 mM β-glycerolphosphate to induce VCa. Calcium content in the extracellular matrix and alkaline phosphatase activity (ALP) were selected as markers of osteoblastic transdifferentiation. Long treatment with 10 nM Pg showed a significant decrease in ALP activity (239.9±21; 203.6±2.9 x10^3 IU, control; Pg, $p<0.02$) and calcium levels (365.1±38.2; 248.2±20.3 μg/mg protein, control; Pg, $p<0.02$). Similar results were obtained when VSMC were exposed to 1 nM MPA (24%; 20% below control, ALP activity; calcium content, $p<0.02$). In order to investigate the effect of agonists on capillary tube formation, the total number of vessel segments was quantified after Giemsa staining using optical microscopy and ImageJ software. The results indicate that both progestins significantly enhanced capillary tube formation (44%; 38% above control, 10 nM Pg; 10 nM MPA respectively, $p<0.05$). VEGF production was measured using an immunoassay. Treatment with 50 nM Pg markedly increased VEGF synthesis (43% above control, $p<0.05$). In contrast, MPA did not affect growth factor synthesis. In summary, both progestins exhibit a favorable action on vascular remodeling through the inhibition of VCa and the stimulation of angiogenesis.

Keywords: progesterone, acetate of medroxyprogesterone, vascular calcification, angiogenesis

(1517) **ROLE OF NLRP3/CASP1/IL-1B AXIS IN RENAL ISCHEMIA/REPERFUSION-INDUCED CARDIAC ELECTRICAL DISTURBANCES**

Maria Micaela Lopez Alarcon (1), Mayra Trentin-Sonoda (2), Fabiano Ferreira (1), Karina Panico (2), Claudia Paiva Neto (1), Emiliano Medei (1), Marcela Sorelli Carneiro-Ramos (2)

(1) Universidade Federal do Rio de Janeiro. (2) Universidade Federal do ABC.

Patients with chronic renal ischemia have a high risk to develop cardiovascular diseases. Therefore, understanding the pathogenic links between renal ischemia and cardiovascular disease is of utmost importance. Previous work of our group showed a systemic peak of IL-1βon the day 8after renal ischemia-reperfusion (IR) in mice. This finding was associated with prolongedQJ on the EKG, an arrhythmogenic marker, sustained up to day 15. We have also demonstrated the important role played by resident heart macrophages in IL-1β release upon NLRP3 inflammasome activation andin cardiac electrical remodeling. Thus, in this work we tested the hypothesis that the activation of NLRP3/Casp1/IL-1β axis is involved in cardiac electrical disturbances promoted by renal IR. In order to investigate the role of NLRP3 inflammasome in cardiac electrical disturbances, *Nlrp3*$^{-/-}$ and *Caspase-1*$^{-/-}$ mice induced with renal IR or Sham were used. Cardiac electrical function was assessing by *in vivo* electrocardiogram (EKG) 15 days post- renal IR. Our data showed that the genetic ablation of NLRP3 or Caspase-1 preventedeither the QJ prolongation ($p<0.01$ and $p<0.001$) and the renal IR-induced systemic peak ofIL-1βon day 8 (measured by ELISA). In fact, renal IR failed to prolong the QJ interval in IL-1r$^{-/-}$ mice. The depletion of macrophages (by Clodronate Liposomes) on day 7 post-renal IR was able to prevent the IR-induced longer QJ observed at day 15 post-IR($p<0.05$). Finally, the daily treatment with IL-1r-antagonist (Anakirna) from day 8 to day 15 reverted the IR-induced longer QJ ($p<0.01$).The data presented here demonstrates that NLRP3/Casp1/IL-1β axis is involved on the induction of prolonged cardiac QJ by renal ischemia/reperfusion. Additionally, the block of the IL-1r was found to be a potential therapeutic approach to revert the IR-induces cardiac changes.

Keysword: renal ischemia-reperfusion, cardiac electrical alterations, NLRP3 inflammasome, IL-1β.

(1880) **LACK OF GALECTIN 3 ALTERS MACROPHAGES POLARIZATION AND CYTOKINES PROFILE DURING THE WOUND HEALING OF MYOCARDIAL INFARCTION IN MICE**

Pablo Cassaglia (1), Nadia Laura Martinez Naya (1), Federico Penas (2), Celeste Betazza (1), Agata Cevey (2), Verónica Volberg (2), Luciana Wilensky (1), Verónica Casanovas (1), Nora Goren (2), Celina Morales (1), Germán E. González (1)

(1) Instituto de Fisiopatología Cardiovascular. Fac. de Medicina. UBA. (2) Fac. de Medicina. UBA.

We previously showed that lack of Galectin 3 (Gal3) reduced the macrophages (MØ) infiltration and fibrosis during the early wound healing after myocardial infarction (MI) leading to adverse cardiac remodeling in mice. However, whether Gal3 alters MØ polarization and cytokines profile during the evolution of wound healing after MI has not been previously investigated. Here we aimed to study whether lack of Gal3 modify the polarization of MØ and changes the proinflammatory and antiinflammatory expression of cytokines during the evolution of wound healing process in mice with MI. Adult male C57 and Gal3KO mice were subjected to permanent coronary artery ligature. After 1 and 4 weeks (w) post-MI echocardiography was performed. LV end-diastolic diameter (LVEDD) was measured and ejection fraction (EF, %) calculated. Then, animals were euthanized and the hearts from animals of 1w were harvested and store (-80ºC). IL10, TNFα and Mannose receptors (MR) were quantified by qPCR. At 4w MI size and fibrosis were quantified in cardiac slices stained with Masson's Trichrome and Picrosirius Red. Results**:** X±SEM; * $p<0.05$ C57 vs Gal3KO. At 7 days post-MI the MØ polarization and cytokine expression were affected in by lacking Gal3. MR were increased from 0.5±0.2 (C57) to 1.8±0.4* (Gal3KO), while IL-10 from 0.7±0.0 (C57) to 2.8±0.3* (Gal3KO). At the same time, TNFα was reduced from 26±0.3 (C57) to 0.4±0.1* (Gal3KO). The lack of Gal3 increased the LVEDD from 4.4±0.1 (C57) to 4.8±0.2* (Gal3KO) and from 4.9±0.2 (C57) to 5.7±0.3* (Gal3KO) simultaneously reduced the EF from 47±2 (C57) to 37±3* (Gal3KO) and from 48±6 (C57) to 39±5 (Gal3KO) at 1 and 4w postMI respectively. Fibrosis at the MI zone was reduced from 91±6 (C57) to 61±3* (Gal3KO). In summary, the lack of Gal3 affected the MØ polarization and the pro and antiinflammatory cytokine profile. Those effects unfavorably modified the evolution of wound healing as observed by reduced fibrosis in the MI zone at 4w and adverse LV remodeling.

(950) **LUNG PRE-FIBROTIC STATUS IN A MOUSE MODEL OF METABOLIC SYNDROME: IMPLICATION OF OXIDATIVE STRESS AND INFLAMMATION.**

Maria Cecilia Della Vedova (1), Sandra E. Gomez Mejiba (2), Nidia N. Gomez (3), Dario Ceferino Ramirez (1)

(1) Laboratorio de Medicina Experimental y traduccional. IMIBIO-SL-CONICET, (2) Laboratorio de Experimentales Terapeuticas. IMIBIO-SL-CONICET, (3) Laboratorio de Morfofisiologia-UNSL

During the last decades there was a sustained increase in morbidity and mortality due to respiratory and metabolic diseases associated with obesity, such as the metabolic syndrome (MS). Components of MS, such as dyslipidemia, hyperglycemia, hypertension

and obesity were independently associated with lung function, but from all of them, obesity is clearly implicated. Herein we aimed at determining the impact of the MS on redox/inflammatory status and potential consequences in the lung using a previously developed mouse model of MS. To achieve this goal, 6 week-old male C57BL / 6J mice were fed for 16 weeks with a low fat- (LFD) or a high fat-diet (HFD, chicken fat) and water supplemented with 10% fructose (F). Thus, the experimental design included 2 groups: LFD (control) HFD+F (MS). At the end of the treatment, lung of the HFD + F group compared to the LFD group had an increase in NOX-2 ($p < 0.05$) and iNOS ($p < 0.05$) expression, generating an imbalance between oxidants and antioxidants. This imbalance produced local oxidative / inflammatory damage, with a consequent decrease in the activity of antioxidant systems (PAT, GSH / GSSG, CAT, SOD and GPx) and an increase of proinflammatory cytokines (TNF-α and IL-6). Oxidative damage increased neutrophil chemotaxis, and the HFD + F group had neutrophils higher retention (ICAM-1 $p < 0.01$) and activation (MPO $p < 0.01$) in lung parenchyma, which led to an increase of connective tissue in the HFD + F group compared to the control. In this study, we report that mice model with MS exhibit lung inflammatory symptoms with an imbalance of the oxidant / antioxidant system towards oxidative stress and inflammation leading to a profibrotic state.

(520) **MECHANISMS OF STUNNING DUE TO ISCHEMIA/ REPERFUSION IN AGED RAT HEARTS AND MITOCHONDRIAL MECHANISMS OF CARDIOPROTECTION: ENERGETICAL STUDY.**

Germán Andrés Colareda (1), Patricia Bonazzola (2), Soledad Inés Matera (1), Alicia Elvira Consolini (1)
(1) Farmacología-GFEYEC, Depto de Cs. Biológicas. Facultad de Ciencias Exactas, UNLP. (2) ININCA Facultad de Medicina, UBA-CONICET.

Age is a cardiac risk, and previous results showed that hearts from >20 months aged female rats (AgF) had less postischaemic contractile recovery (PICR) and muscle economy than young female (YF) and male (YM) rats exposed to moderate I/R (I/Rm, 20 min I/45 min R) but similar in severe I/R (I/Rs, 30 min I/45min R) (SAFE 2016). The aim of this work was to evaluate the underlying mechanisms of stunning in the AgF. Isolated hearts were perfused inside a calorimeter at 37°C to measure left ventricular pressure (LVP, in mmHg) and total heat rate (Ht, in mW) during exposition to I/Rs. To evaluate whether the SR Ca^{2+} content and release was altered by age, AgF hearts were exposed to 30 min I and R with Krebs-10 mM caffeine-2 mM Ca-36 mM Na, and the consequent contracture (ΔLVP) and ΔHt were measured as well as the respectives area-under-curves (AUC) over the ischemic line. The AgF hearts developed similar AUC-LVP (2834.9±647.9 mmHg.s) and AUC-Ht (419.3±32.7 $mJ.g^{-1}$) than Y hearts (2152.6±492.8 mmHg.s and 441.2±62.5 $mJ.g^{-1}$, respectively). In order to evaluate the role of mitochondrial transporters in the stunning, AgF hearts were perfused with 10 μM clonazepam (Clzp) to block the mNCX before I/Rs. Clzp increased PICR from 13.3±3.0% to 42.7±5.8% ($p<0.05$) during R, as well as muscle economy (P/Ht) from 1.0±0.2 to 2.2±0.3 $mmHg.mW^{-1}.g$), while reduced diastolic contracture (+ΔLVEDP from 74.9±9.1 to 25.5±7.2 mmHg). To evaluate the role of mKATP channels in AgF, hearts were perfused with 30 μM diazoxide (Dzx) before I/Rs. The PICR was increased up to 62.6±7.3 % at the end of R ($p<0.05$) as well as P/Ht (to 3.2±0.8) while reduced ΔLVEDP. Results suggest that: a) the low cardioprotection associated to the age was not due to a low SR Ca^{2+} store and release, b) mitochondrial $[Ca^{2+}]$ of AgF has influence on stunning, since PICR, could be improved by reducing the mitochondrial Ca^{2+} extrusion through mNCX, c) as in Y hearts, activation of mKATP channels improves PICR of AgF. *UNLP-X-795.*

(913) **A DUAL DEATH/SURVIVAL ROLE OF AUTOPHAGY IN THE ADULT OVARY OF *LAGOSTOMUS MAXIMUS* (MAMMALIA- RODENTIA).**

Noelia Leopardo, Mariela Velazquez, Pablo Inserra, Julia Halperín, Verónica Dorfman, Alfredo Vitullo
CEBBAD-Universidad Maimónides

The follicle reserve in the mammalian ovary is lost from the fetal/perinatal period and throughout post-natal lifespan mainly through apoptosis-driven follicular atresia. However, other cell death mechanisms such as autophagy, seem to be also involved. The South American plain vizcacha, *Lagostomus maximus* (*L.m),* shows massive ovulation and a very low or suppressed apoptosis-dependent follicular atresia. Here we investigated autophagy markers in the adult ovary of *L.m* aimed to discern a possible role of autophagy proteins in germ cell death or survival. A total of 14 adult female ovaries were screened for the expression of BECLIN1, LC3B, LAMP1, *cleaved CASPASE-3* and BCL2 by immunohistochemistry (IHQ), western blot (WB) and protein co-expression by confocal microscopy. The presence of autophagosomes (AP) and autolysosomes (AL) in follicles and corpora lutea (CL) was analyzed by electron microscopy (EM). Ovary explants were incubated in culture starvation media to determine whether autophagy was triggered by a stress stimulus. Ovary explants incubated in enriched culture media were used as controls. Strong BECLIN1, LC3Band LAMP1 staining was observed in atretic follicles (AF) and degenerating CL that also expressed nuclear cleaved-CASPASE-3 . Non-atretic follicles showed a slight expression of autophagy proteins but a strong expression of BCL2 and negative expression of cleaved CASPASE-3. In cultured ovaries, BECLIN1, LC3B-II and LAMP1 were significantly increased in starvation condition ($p<0,05$). EM revealed a high formation of AP and AL in AF and CL and a low number of autophagic vesicles in non atretic follicles. The co-expression of LC3B-BECLIN1, LC3B-LAMP1 and LC3B-CASPASE-3 was only detected in AF and CL, while co-expression of BCL2-BECLIN1 was only observed in non-atretic follicles. These results suggest a dual role of autophagy in the ovary of *L.m.* inducing cell death in AF and CL and promoting cell survival in non atretic follicles.

Keywords: autophagy, ovary, germ cell, vizcacha.

Objetive: To study the expression of steroidogenic proteins, the release of estradiol and progesterone, the ovulation and luteal size in the ovary of rats with experimentally induced endometriosis

Materials and Methods: Endometriosis was surgically induced in Sprague Dawley rats by autotransplantation of uterine horn pieces to the bowel mesothelium. Sham animals were used as controls. Rats were sacrificed one month after surgery at different stages of menstrual cycle (proestrus, estrous and diestrus). Luteal size was measured in ovary sections stained with hematoxylin-eosin. Aromatase P450, P450scc, 3β-HSD and StAR expression was assessed by western blot in isolated follicles and corpora lutea (CL). Estradiol and progesterone serum levels were evaluated by RIA. Ovulated oocytes were counted in the ampulla in the morning of estrous.

Results: StAR expression decreased in follicles from rats with endometriosis in all estrous cycle stages ($p<0,001$) and increased in CL during estrus ($p<0,05$). P450scc expression decreased in

follicles during proestrus (p<0,05) and increased in CL during estrus (p<0,001) in rats with endometriosis compared to sham rats. 3β-HSD expression diminished in CL from rats with endometriosis during proestrus (p<0,05). Aromatase P450 expression decreased in CL (p<0,001) and follicles (p<0,01) in diestrus and increased in CL during estrus (p<0,01) in rats with endometriosis. Serum levels of estradiol were decreased (p<0,01) and progesterone serum levels were increased (p<0,01) in rats with endometriosis in all estrus cycle stages. Related to these results, CL size was increased (p<0,05) in diestrus and the number of ovulated oocytes was diminished (p<0,05) in rats with endometriosis compared to the sham ones.

Conclusion: Our results suggest that experimental endometriosis in rats alters steroidogenic proteins expression in ovary leading to endocrine and ovulatory changes and a delay in structural luteolysis.

During lactation, sustained hyperprolactinemia is maintained by the suckling stimulus and decreased hypothalamic sensitivity to prolactin (PRL) negative feedback, that maintains a reduced dopaminergic tone. OFA (hr/hr) rats, derived from the Sprague Dawley (SD) strain have deficient lactation, high hypothalamic dopaminergic tone and a blockade in suckling induced PRL release. Hyperthyroid rats also have deficient lactation, caused by increased hypothalamic sensitivity to PRL negative feedback that leads to a partial blockade in suckling induced PRL release. Thus, both groups show elevated dopaminergic tone responsible for the decreased PRL release and lactation failure. This evidence suggests that thyroid hormones may be also involved in prolactin regulation during lactation. We investigated the changes in hypothalamic thyroid hormone receptors (TR) expression in response to the suckling stimulus in OFA rats compared to SD rats (normal lactation). Using real time quantitative RT-PCR, we measured the changes in hypothalamic mRNA expression of TRβ isoforms 1 and 2 and TRα isoforms 1 and 2, in mid-lactating OFA and SD rats, continuously suckled (CL), separated from their pups for 12 h (Sep), or separated and subsequently suckled during 2 (S2) or 4 (S4) h. We also determined serum PRL levels by RIA and litter weight gain. After suckling, PRL release and litter weight gain were higher (p<0.05) in SD than OFA rats. In SD rats, separation had no effect, but S2 and S4 induced increases in all TR isoforms mRNAs (p<0.01). OFA CL and Sep rats had higher values of all TR isoforms compared with SD rats (p<0.05), and they decreased after suckling to lower values (p<0.05) than in SD rats for TRβ1, TRα1 and TRα2. These results show that lactating OFA rats have differential hypothalamic TRs expression patterns in response to suckling, suggesting that they may be involved in the regulation of the negative PRL feedback mechanism present in neuroendocrine dopaminergic neurons.

Humanin (HN) peptides have cytoprotective action in several cell types such as neurons, spermatogonias and Leydig cells. Our previous results showed that HN peptides are expressed in normal ovarian cells, being localized in granulose cells, theca cells and oocytes. Also, we observed that HN is expressed in the human granulosa-like tumor cell line (KGN). In addition, we showed that HN increases the viability of KGN cells. The aim of present study was to explore the function of HN peptides in the ovary from adult rats and KGN cells. To evaluate the effect of endogenous HN, we used a baculovirus encoding a shRNA to inhibit HN expression (BV shHN). We injected BV shHN and control baculovirus (BV control) into the ovarian bursa of adult rats. In ovarian sections stained with hematoxylin-eosin, we observed that BV shHN injection reduced the cortex area whereas increased the stroma area. The inhibition of HN expression increased the percentage of atretic follicles (BV control: 15%; BV shRNA: 78%, $p < 0.01$, $\chi 2$). In addition, we studied the effect of silencing HN expression on the apoptosis in follicles by TUNEL. BV shRNA increased the percentage of follicles with apoptosis (BV control: 11%; BV shHN: 31%, $p < 0.01$, $\chi 2$). Also, to evaluate the function of endogenous HN in KGN cells, they were transduced with BV shHN or BV control. The inhibition of HN expression changed the morphology of KGN cells, which become elongated and fibroblast-like, and increased the percentage of apoptosis of KGN cells (BV control: 0.3%; BV shRNA: 4%, $p < 0.01$, $\chi 2$). Considering that the inhibition of endogenous HN modifies the morphology of KGN cells, the architecture of the ovary and increases the percentage of apoptotic KGN cells and follicles with apoptosis, our results suggest that HN peptides exert a cytoprotective action in normal and tumor ovarian cells. HN arises as a novel cytoprotective factor that could play a role in ovarian physiology and pathology.

(1342) **NEONATAL EXPOSURE OF EWE LAMBS TO A GLYPHOSATE-BASED HERBICIDE ADVERSELY AFFECTS OVARIAN FOLLICULAR DEVELOPMENT INDEPENDENTLY OF ADMINISTRATION ROUTE**

Oscar Edgardo Rivera (1), Gisela Haydée Dioguardi (1), Norberto Miguel Belmonte (1), Ramiro Alarcón (2), Paola Ingaramo (2), Mónica Milagros Muñoz-De-Toro (2), Enrique Hugo Luque (2)
(1) IIPAAS-FCA-UNLZ. (2) ISAL-CONICET-FBCB-UNL.

Glyphosate-based herbicides (GBH) are widely used around the world. Previous studies suggest that GBH may act as endocrine disruptor. Our hypothesis suggests that low doses of GBH affect ovarian ovine development. Ewe lambs were exposed from postnatal day (PND) 1 to PND14 to sc (n: 13) or orally (n: 5) environmentally relevant doses of GBH (2 mg/Kg/day, EPA reference dose) and controls (n: 13) with saline solution. On PND 45 ovaries were weighted and paraffin-embedded, sectioned in 4 adjacent 5 μm -serial sections taken 200 μm apart. Follicular dynamic was established by histomorphological features on picrosirious-hematoxilin-stained sections (8 sections/ovary). Follicles of different types and multioocyte follicles were expressed as a percentage. Immunohistochemistry of androgen receptor (AR) and Ki (proliferation marker) were evaluated. Proliferation was measured in granulose (GC) and theca cells (TC) of antral follicles. GBH treatment did not alter ovarian weight, total number of follicles or AR expression. Lambs exposed to GBH showed a reduction of primordial follicles (C=87.9±2.7; scGBH=57.8±3.9; oGBH=62.7±5.4) together with an increase of transitory (C=6.8±1.7; scGBH=36.2±3.3; oGBH=30.7±4.6) and primary (C=1.4±0.2; scGBH=4.4±0.9; oGBH=5.2±1) follicles. In addition, GBH treatment increased the percentage of atretic follicles (C=29.0±3.7; scGBH=44.3±4.0; oGBH=44.3±2.9) and induced higher proliferation of GC (C=26.3±5.5; scGBH=43.3±5.1; oGBH=52.8±11.1) and TC (C=4.9±0.9; scGBH=11.1±1.6; oGBH=28.7±4.8) in antral follicles. Moreover, an increased incidence of multioocyte follicles (C=0.1±0.1; scGBH=1.3±0.4; oGBH=1.1±0.3) was observed. Our results demonstrated that neonatal exposure to low doses of GBH disrupts the ovine follicular development independently of administration route, showing no differences between sc and oral treatment. Further studies with the same GBH protocol will define whether the described effects have consequences in the adult ovarian function.

Keywords: glyphosate, neonatal exposure, ovary

(668) **RESVERATROL REDUCES DOXORUBICIN-INDUCED OVARIAN DAMAGE IN MICE OVARY**

Gonzalo Oubiña, Natalia Pascuali, Mariana Di Pietro, Analía Ricci, Leopoldina Scotti, Abramovich Dalhia, Parborell Fernanda

IByME

Premature Ovarian Failure (POF) is characterized by the disappearance of ovarian follicles in young women, which may be caused by chemotherapy. POF treatments such as hormone therapies are not completely effective. We evaluated whether Resveratrol (Rs) can prevent gonadotoxicity caused by doxorubicin (Dx) in a mouse model. F1 mice (BalbC x C57 / BL6) (8 weeks) were given either an single intraperitoneal injection of Dx (10mg/kg) or saline solution. Control and Dx mice underwent sham surgery and received an intrabursal injection of saline solution, while Dx+Rs groups received 1μM or 10μM of Rs intrabursa, 1h prior to Dx administration. Animals were sacrificed 2 weeks after surgery (n=5-8/ group) and ovaries were removed, one for Western Blot (WB) and the other for histological analysis. Paraffin-embedded ovarian slides were stained in H&E for morphological study or immunostained for DDX4 (germ-line cell specific marker) and AMH (ovarian reserve marker). Results were evaluated by ANOVA followed by Dunnet's test.

Dx reduced the % of primary follicles compared to control ($p<0,05$) while Dx+Rs10μM increased it ($p<0,05$). Dx increased the % of atretic follicles compared to control ($p<0,05$) but Rs10μM restored these values. Dx decreased the number of primordial follicles compared to control ($p<0,05$), but Dx+Rs1μM maintained control values, as studied by DDX4 immunostaining. By WB, Dx decreased protein expression of AMH compared to control ($p<0,05$), while Dx+Rs10uM increased its expression compared to Dx alone ($p<0.01$), which was corroborated by IHC. Since Rs induces the expression of ovarian sirtuin 1 (SIRT1) and modulates follicular development, we evaluated this protein. Dx reduced SIRT1 expression ($p<0,05$) but Rs (1-10μM) restored it to control values.

Our results suggest that Rs can protect the ovary from gonadotoxic injury by Dx, as shown by its effects on follicular dynamics and ovarian reserve. Rs could be a novel strategy for fertility preservation in cancer patients.

(646) **STEM CELL MARKERS OCT3/4, SOX2 AND SOX17 IN ADULT OVARY OF *Lagostomus maximus***

Maria Itati Albamonte, Florencia Magali Mignolo, Noelia Leopardo, Verónica Dorfman, Alfredo Vitullo, Julia Halperin
Centro de Estudios Biomédicos, Biotecnológicos, Ambientales y Diagnóstico, CEBBAD-Universidad Maimónides, Buenos Aires, CONICET, Buenos Aires, Argentina.

Lagostomus maximus (Rodentia: Chinchillidae) does not show apoptosis as a mechanism of intra-ovarian elimination of germ cells (GCs); moreover, it shows a continuous production of GCs suggesting *de novo* GC generation in the adult ovary. We investigated the expression of pluripotent markers in ovaries of non-pregnant, early-, mid- and term-pregnant vizcachas. We semi-quantified the different follicular stages (primordial, primary, secondary, pre-antral, antral and corpora lutea) in the ovaries of each experimental group and examined the expressions of Oct3/4, Sox2 and Sox17 in ovary cross-sections by immunohistochemistry. Although ovaries from all the experimental groups exhibited all follicular structures, the markers analyzed showed a distinctive expression pattern: neither Sox2 nor Sox17 were detected in any ovarian structure at any of the reproductive stages studied. Yet, Oct3/4 was observed in nuclei and/or cytoplasm of the oocyte in primary, secondary, pre-antral and antral follicles. Cytoplasm Oct3/4 expression is related with the survival of GCs during its maturation. Oct3/4 appears to be up-regulated in oocytes of both primary and growing (secondary and antral) follicles of adult females. This up-regulation would be occurring at the completion of the prophase I of meiotic division which would suggest a specific involvement of this transcription factor in oocyte growth.

Key words: stem cells, adult ovary, *Lagostomus maximus*

(334) **PROTEIN EXPRESSION AND CELLULAR LOCALIZATION OF ESTROGEN RECEPTORS ALPHA AND BETA IN ENDOMETRIOSIS-ASSOCIATED EPITHELIAL OVARIAN CANCER CELL LINES**

Juan Ignacio Bastón (1), Luciana Ferella (1), José Javier Singla (2), Alejandro Martín Gonzalez (3), Gabriela Fabiana Meresman (1)
(1) Laboratorio de Fisiopatología Endometrial, Instituto de Biología y Medicina Experimental (IBYME) - CONICET; Buenos Aires, Argentina. (2) Hospital de Clínicas "José de San Martín", Buenos Aires, Argentina. (3) Hospital Naval de Buenos Aires "Cirujano Mayor Dr. Pedro Mallo", Buenos Aires, Argentina.

The potential role of the estradiol secreted by endometriotic lesions on the pathophysiological mechanisms of endometriosis-associated epithelial ovarian cancer (EOC), such as endometrioid and clear-cell epithelial ovarian tumors, is not yet entirely known. So, the main objective of this study was to evaluate the protein expression and cellular localization of Estrogen Receptors alpha (ERα) and beta (ERβ) in cell lines derived from human endometriosis-associated EOCs. Human TOV-112D cell line derived from an endometrioid-type ovarian carcinoma and human TOV-21G cell line derived from a clear-cell ovarian carcinoma were cultured under standard conditions until confluence to further analysis of ERα and ERβ protein expression and cellular localization, in 4 independent experiments, by Western blot and indirect immunofluorescence respectively. We found that both endometriosis-associated ovarian cancer cell lines expressed the canonical steroid receptor proteins, being ERα expression stronger than ERβ in both cell lines. In addition, ERα was mainly localized into the cellular nucleus, whereas ERβ was mostly localized into cytoplasm. These results suggest that these cell lines are endowed with the necessary molecular machinery to respond to estradiol, becoming them as a suitable *in vitro* model to study the potential role of steroid hormones secreted by endometriotic lesions on the onset and development of endometriosis-associated EOCs. This is an initial descriptive study, so functional studies will be addressed to fully understand the role of the estradiol secreted by endometriotic lesion on the pathophysiological mechanisms underlying the etiology of endometriosis-associated EOCs.

(435) **ANDROGEN EXCESS DURING PRENATAL LIFE AFFECTS HEPATIC LIPOGENESIS IN A MURINE PCOS MODEL AT ADULT LIFE**

Aimé Florencia Silva, Giselle Adriana Abruzzese, María Florencia Heber, Ailicia Beatriz Motta
Laboratorio de Fisio-patología Ovárica, Centro de Estudios Farmacológicos y Botánicos (CEFYBO), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Facultad de Medicina, Universidad de Buenos Aires (UBA), Buenos Aires, Argentina.

Prenatal androgen excess is considered as one of the main factors contributing to the development of Polycystic Ovary Syndrome (PCOS). Most of PCOS patients present hyperinsulinemia or Insulin Resistance (IR) which are associated with different metabolic disorders such as nonalcoholic fatty liver disease (NAFLD) and steatosis. In previous results, at puberal stage (60 days of age), we have shown that prenatal hyperandrogenism affects hepatic lipogenesis, thus leading to a high risk of developing steatosis.

This study aimed to evaluate the effect of prenatal hyperandrogenism on the regulation of lipogenesis in the liver at adult life (90 days of age).

Pregnant rats were hyperandrogenized with testosterone and a control group was obtained by the injection of vehicle. The prenatally hyperandrogenized (PH) female offspring (N=150) and control offspring (C, N=96) were characterized according to the estrous cycle as ovulatory (PHov) and anovulatory (PHanov) phenotypes at adult age. The gene expression of PPARg, SREBP and ChREBP (lipogenic enzyme's modulators), PPARa (involved in b-oxidation) and chemerin (adipokine associated with IR and NAFLD disorders) were quantified by qPCR. In addition, the hepatic triglyceride content was quantified by an enzymatic kit.

We found that PPARg, SREBP and ChREBP mRNA levels were lower in both phenotypes (PHov and PHanov) than in the control group ($p<0.01$). On the other hand, PPARa and chemerin mRNA levels were not affected in the PH groups and no difference was found in hepatic triglyceride content relative to the control ($p>0.05$).

We conclude that the alterations promoting lipogenesis observed at puberal age are not maintained at long term. Instead, at adult age, the inhibition in this pathway may be preventing the possible accumulation of hepatic triglycerides. Nevertheless further research is needed as they might be involved in energy imbalance processes.

Keywords: PCOS, lipogenesis, hyperandrogenism, liver, developmental programming.

(291) **STROMAL-DERIVED FACTOR-1 (SDF-1) DIRECTLY PROMOTES GENES EXPRESSED WITHIN THE OVULATORY CASCADE**

Julieta L. Rojo (1), Kelly A. Young (2), Martina Linari (1), Marina C. Peluffo (1)
(1) CEDIE-CONICET. (2) CSULB (California State University-Long Beach).

SDF1, a chemokine that is expressed in multiple tissue types including the ovary, serves as the ligand to chemokine CXC-motif receptor-4 (CXCR4). While LH upregulates follicular CXCR4, the role that SDF1/CXCR4 signaling might play in the COC (cumulus-oocyte complex) was unknown. We hypothesized that the SDF1/CXCR4 system was present in feline COCs and that COCs culture with SDF1 would directly upregulate genes expressed in the ovulatory cascade (HAS2, TSG6, AREG, and GDF9). To address this hypothesis, a COC culture was established. Ovaries (n= 50) were obtained from adult domestic cats during breeding season and COCs were mechanically recovered from antral follicles. The culture environment was optimized by testing different conditions (media, serums, serum concentrations and pretreatments). During culture optimization, COCs (n=24) were cultured at different time-points (3, 12 and 24h) with and without gonadotropins (GNT). Then, the effects of 25ng/ml SDF1 and CXCR-4 inhibitor were examined in the COC at all time-points (n=48) and gene expression was assessed by real-time PCR. CXCR4 and SDF1 immunofluorescence was also performed. MEM-hepes with 1% of charcoal stripped-FBS was the optimum medium for this culture, as seen by the expansion of the COC at 24h. The mRNA expression of HAS2, TSG6, and AREG peaked at 3h in the GNT group as compared to GNT treatment in the 12 and 24h groups, and as compared to negative controls ($p<0.05$). COCs cultured with 25ng/ml SDF1 showed increased HAS2 and TSG6 mRNA expression at 3h as compared to negative controls and the CXCR4 inhibitor group. CXCR4 and SDF1 immunostaining was present in both cumulus cells and the oocyte. In summary, these results suggest that this model can be used to examine molecular processes within the COC. In addition, the SDF1-CXCR4 pathway may extend its function beyond chemoattractant, and may play a role in cumulus cells via upregulation of key ovulatory genes concomitant with GNT stimulation.

Keywords: ovary, feline, chemokines, cumulus oocyte complex.

(1143) **EFFECTS OF IL-1**B **ON ADRENAL STEROIDOGENESIS AND MIRNA EXPRESSION BY *IN VITRO* STUDIES IN THE NCI-H295R HUMAN CELL LINE.**

Natalia Santucci (1), Eduardo Brandao (1), Leandra Linhares Lacerda (2), Marcelo Ribeiro Alves (3), Silvana Spinelli (1), María Luisa Bay (1), Oscar Bottasso (1)
(1) IDICER-CONICET-UNR, (2) LPT-IOC-Fiocruz (RJ, Brasil), (3) ECRC-Fiocruz (RJ, Brasil).

The adrenal gland is a key component of the hypothalamus–pituitary–adrenal (HPA) axis, playing a crucial role in the adaptation of organism to stressors. Adrenal steroidogenesis is a vital process widely regulated at several stages. Immune mediators released during infections are known to influence adrenal steroidogenesis, as is the case of tuberculosis (TB), in which the prolonged presence of the pathogen together with an exacerbated immune response is likely to alter the endocrine profile. IL-1β which is mainly produced by macrophages is a key mediator in TB. Beyond its immunological effects, IL-1β stimulates the production of ACTH and the ensuing cortisol release. However it is not well known whether this cytokine exerts a local effect on the adrenal gland itself. As such, we decided to study the effect of different concentrations of IL-1β, at 6, 12, 24 and 48 h, in the human cell line NCI-H295R, derived from a carcinoma of adrenal cortex, stimulated with Forskolin (Fk), or not. Treatment with IL-1β 1.25 pg/ml + Fk during 24 h resulted in an increased cortisol and DHEA production ($p<0.05$) in comparison to cultures only stimulated with Fk or no treatment (Basal). Given that MicroRNAs are endogenous small noncoding RNAs that decrease the expression levels of specific genes by translational repression, sequestration, and degradation of their mRNAs; we next explored eventual changes in the microRNAs (miRNAs) profile of cells exposed to IL-1β 1.25 pg/ml + Fk during 24 h. Six out of 84 analyzed miRNAs showed a differential expression, depending on treatment conditions. MiRNAS 17-5p, 26a-5p, 93, 484 and 499a-5p were augmented in cultures treated with IL-1β + Fk ($p<0.05$, vs. Fk only) while MiRNA 206 was diminished in Fsk-treated or Basal cultures ($p<0.05$). The IL-1β-induced changes in hormonal secretion by NCI-H295R cells coexist with certain modifications in the miRNA profile which may bear relation with the regulatory mechanisms underlying adrenal steroid production.

(36) **EXPRESSION OF STEROIDOGENIC ENZYMES IN PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC) OF HEALTHY INDIVIDUALS AND ITS ASSOCIATION WITH AGE AND SEX.**

Luisa Gaydou (1,2), María Virginia Tschopp (2), Verónica Lis Bosquiazzo (1,2), Jorge Guillermo Ramos (1,2)
(1) Departamento de Bioquímica Clínica y Cuantitativa, Facultad de Bioquímica y Ciencias Biológicas, UNL. (2) Instituto de Salud y Ambiente del Litoral -CONICET. Universidad Nacional del Litoral.

There is strong evidence that cells of the immune system can secrete a wide variety of hormones, however little is known about their function, or its association with certain pathologies. Our goal was to study the expression of different enzymes related to steroid synthesis in PBMC from healthy individuals. We separated PBMC from males and females of ages 25 – 90 using a Ficoll gradient, RNA was obtained with Trizol reagent, and reverse transcribed to obtain cDNA. We designed primers for aromatase (Aro), 5α-reductase (5aR) 1, 2 and 3, and 3β hydroxysteroid dehydrogenase (3bHSD). Real-Time PCR was performed using L19 as a housekeeping gene. Statistical analysis were carried out using R software. We found that 5aR1, 5aR3 and 3bHSD were expressed on PBMCs, but not Aro or 5aR2. Moreover, 5aR1 showed correlation with age in men (P=0,049), with a significantly higher expression in men older than 50 years (P=0,0257). When comparing both sexes, we found higher values of 5aR1 in men vs women older than 50 years (P= 0,0262). Concerning 5aR3, we found a higher expression in women older than 40 vs younger than 40 years (P=0,0399), and when we compared men and women, we found higher levels of enzyme expression in males older than 50 years (P=0,0371). These findings demonstrate that PBMCs have the required machinery to produce several sex-related hormones, and that these effects are more noticeable at a higher age, when hormone production from endocrine organs decreases. Future studies will compare these findings with the expression of steroidogenic enzymes in Chronic Lymphocytic Leukemia (CLL) samples, taking into account that CLL is more frequent in people older than 50 years, and has a sex dimorphism, being men more susceptible than women.

Keywords: steroid synthesis; peripheral blood mononuclear cells.

(1453) **INTRACRINOLOGY: VASCULAR ENDOTHELIUM AS TARGECT OF DEHYDROEPIANDROSTENEDIONE ACTION**

Adrián Campelo, Pablo Cutini, Virginia Massheimer
Instituto de Ciencias Biológicas y Biomédicas del Sur (INIBIOSUR), Dpto BByF Universidad Nacional del Sur CONICET Bahía Blanca, Argentina.

According to intracrinology, active sex steroid hormones can be locally synthesized from their precursor Dehydroepiandrostenedione (DHEA). In vascular system sex hormones regulate cell migration, proliferation, production of nitric oxide (NO) and adhesion of plate-

lets (PT) and monocytes to endothelial cells (EC). We evaluated the effect of DHEA on these events and evaluated if they were assessed by DHEA, or if conversion to other sex steroids is required.

Primary cultures of rat aortic EC were obtained from Wistar rats and exposed to DHEA (20nM-2mM 0.5-48h). DHEA stimulated NO production (Griess reaction 0.17±0.02; 0.24±0.04; nmols NO/mg prot, Cont; DHEA p<0.01), effect that was not affected by pretreatment with androgen or estrogen receptor antagonists (flutamide or ICI182780). In contrast, when DHEA conversion to androstenedione was blocked by trilostane (TRI) an inhibition of NO synthesis was observed (55-65% 95%CI).

PT adhesion to endothelium was significantly reduced by DHEA, effect that was suppressed by pretreatment of EC with the NOS inhibitor L-NAME (35±6, 25±5, 34±6, 33±7 adhered PT/field cont, DHEA, L-NAME, DHEA+L-NAME p<0.05) suggesting that NO production is required. Monocytes adhesion to EC was also prevented by DHEA (55-65% below cont 95% CI), effect that was significantly inhibited by TRI.

Angiogenic process requires EC proliferation and migration. EC proliferation (neutral red uptake) was enhanced by DHEA (15-22% above cont 95% CI). Migration assays (wound healing) showed that DHEA also induced EC migration, effect that was significantly inhibited by TRI (10±2, 42±8, 12±2, 25±9 Cont, DHEA, TRI, DHEA+TRI migrating cells/field p<0.01). Capillary tube formation in fibrin gells was evaluated. A twofold increase of basal effect was observed with DHEA 0.2 and 2mM p<0.01.

Our results provide evidence of a direct action of DHEA on vessel cells that is mediated by intracrinology mechanisms and may be of physiological relevance in vascular homeostasis.

Keywords: DHEA, intracrinology, vascular endothelium

(1241) **PRO-INFLAMMATORY CYTOKINES AND EPAC2 AS POSSIBLE MODULATORS OF ADRENAL STEROIDOGENESIS DURING EXPERIMENTAL *TRYPANOSOMA CRUZI* INFECTION**

Eduardo Roggero (1), Esdras da Silva Oliveira Barbosa (1), Flavia Lambertucci (2), Florencia Gonzalez (1), Vinicius de Frias Carvalho (3), Oscar Bottasso (1), M. Teresa Ronco (2), Ana Rosa Pérez (1), Silvina R Villar (1)

(1) Instituto de Inmunología Clínica y Experimental de Rosario (IDICER UNR-CONICET), Rosario, Argentina, (2) Instituto de Fisiología Experimental (IFICE CONICET), Rosario, Argentina, (3) Oswaldo Cruz Institute, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil, (4)

During inflammatory or infectious stress, the HPA axis is activated by immune mediators. Adrenal steroidogenesis is a dynamic process, under the stimulation of ACTH, this process, depends on the activation of signaling pathways particularly mediated by PKA. However, glucocorticoid (GC) synthesis can be stimulated by cytokines and Exchange Protein directly Activated by cAMP 2 (Epac2) troughs PKA-independent pathway. Previous studies in mice infected with *Trypanosoma cruzi* (Tc) showed increased circulating levels of GC without changes in ACTH at 17 days post-infection (dpi), while an increase of intra-adrenal expression of pro-inflammatory cytokines was observed. In this study, we determined at different dpi the expression of PKA/PKAp (as a measure of ACTH-pathway activation), IL-1 receptor (IL-1R) and Epac2 (as a potential modulator of adrenal steroideogénesis). C57BL/6 mice were infected with Tc or inoculated with saline (Co). Data are showed as mean±SEM (n=3-5/day/group). Assessments were made between 10 to 16 dpi. IL-1β is increased in plasma during infection [IL-1β (ELISA, pg/ml); Co:22.7±9.0, Tc(11dpi):59±34.6*, Tc(16dpi):82.13±27.2*, *p<0.05 vs Co]. The PKA/PKAp ratio was increased at 11 dpi [Western blot, PKA/PKAp: Co=1±01; Tc(10dpi)=1.1±0.1; Tc(11dpi)=2.4±0.7*; Tc(12dpi)=0.8±0.5; Tc(13dpi)=1.0±0.2; Tc(14dpi)=1.1±0.2; Tc(15dpi)=0.9±0.2; Tc(16dpi)=0.8±0.1; *p<0,05 vs Co]. Tc mice displayed an intra-adrenal elevation of Epac2 after 14dpi (p<0,05 vs Co), decreasing after 16dpi. In parallel, the expression levels of IL-1R start to increase from 13dpi (Western blot, p<0,05). Tc infection activates the steroidogenic synthesis which results in remarkably increased GC production. Our results suggest that at the beginning, GC secretion may be increase by the ACTH-mediated response, but in a late phase of infection, GC secretion might be maintained by other mediators including IL-1 and Epac2.

Keywords: Glucocorticoid; Cytokines; Trypanosoma cruzi; HPA axis

(847) **ROLE OF ALTERNATIVE BACKDOOR PATHWAY METABOLITES ON HUMAN ADRENOCORTICAL STEROIDOGENESIS**

Francisco Lanciotti (1, 2), Diego Colman (1), Verónica Zaidman (1), Mercedes Maceiras (1), Juan Manuel Lazzati (1), Mauro Caparrelli (1), Hayellen Reijenstein (1), Leandro Lauferman (1), Julia Minetto (1), Paula Aliberti (1, 2), Oscar Imventarza (1), Alicia Belgorosky (1, 2), María Sonia Baquedano (1, 2)

(1) Hospital de Pediatría Garrahan, Buenos Aires, (2) CONICET.

The backdoor pathway for androgen synthesis is initiated when 17OHprogesterone (17OHP) is 5α-reduced and then converted to pdiol, substrate for CYP17A1, leading to androsterone and then DHT without the intermediacy of DHEA, androstenedione and testosterone. LC– and GC-MS/MS analysis of urinary steroids showed this pathway is active in pathological states in which adrenal 17OHP accumulates. However, its relevance to human adrenal physiology is unknown. We have previously described the mRNA expression of the backdoor pathway genes to complete all the steps to DHT in the postnatal human adrenal gland. Furthermore, functional studies in H295R human adrenocarcinoma cells gave first hints that DHT may participate in the regulation of adrenal steroidogenesis through inhibition of CYP17A1 activity (ENDO 2014, SAIC 2015). To provide further evidence for the presence of the backdoor pathway and its role in postnatal human adrenal cortex, human adrenal tissues (HAT) were collected from 3 age groups: Gr1: <3 months, n=4, fetal zone involution; Gr2: 3 months to 6 yr, n=4, pre-adrenarche; and Gr3: >6yr (14-40yr; median= 17y), n=7, post-adrenarche. Immunohistochemistry confirmed protein 5α-reductase 1 (SRD5A1) expression in HAT from the 3 age Gr. HAT from Gr3 were used to prepare primary cultures of human adrenocortical cells (HAC). HAC were treated in the presence or absence of ACTH (10nM) with or without DHT or androsterone for 18-48h. In a dose-dependent manner at concentrations ≥1μM, DHT significantly decreased cortisol and stimulated progesterone basal (-1.7 to -3.8 and 1.8 to 3.4 fold, respectively) and ACTH-induced (-1.5 to -4.7 and 1.5 to 2.2, respectively) production (Log Transformation ANOVA-Dunnett's Test; p<0.05). Comparable results were observed with androsterone incubation of HAC. Altogether, our data suggested that intraadrenal backdoor pathway metabolites might have physiological significance as paracrine/autocrine regulators of adrenocortical function.

(515) **VITAMIN D REGULATES STEROIDOGENESIS AND INFLUENCES THE EXPRESSION OF SEVERAL COMPONENTS OF THE HISTAMINERGIC SYSTEM IN R2C TUMOR LEYDIG CELLS.**

María Luisa Varela (1), Adriana María Belén Abiuso (1), Marcos Besio Moreno (1), Omar Pedro Pignataro (1), Pablo Knoblovits (2), Sebastián Suárez (2), Pablo René Costanzo (2), Carolina Mondillo (1)

(1) Laboratorio de Endocrinología Molecular y Transducción de Señales, Instituto de Biología y Medicina Experimental (IBYME-CONICET), Buenos Aires, Argentina. (2) Servicio de Endocrinología, Metabolismo y Medicina Nuclear, Hospital Italiano de Buenos Aires. C.A.B.A., Argentina.

Leydig cell tumors (LCT) are endocrine tumors of the testicular interstitium. Current evidence indicates that aromatase (CYP19) overexpression and excessive estrogen (E2) production play a crucial part in their genesis. Although most LCT are benign, malignant LCT respond poorly to chemo/radiotherapy, underscoring the importance of developing novel therapeutic strategies. Bioactive vitamin D (calcitriol; CAL) is a steroid hormone with a major role in human health. CAL binds to nuclear vitamin D receptor (VDR), a ligand-inducible

transcription factor that functions to control target gene expression. Vitamin D deficiency has been linked to various malignancies, including cancer. Previously, we reported that histamine (HA) is an autocrine growth factor in LCT. Also, we detected VDR in human Leydig cell (LC) hyperplasia and LCT. Several components of the HA-ergic system are targets of VDR, and CAL regulates CYP19 in many cell types. Thus, to assess the question whether CAL plays a role in LCT, we studied its ability to modulate the expression of genes involved in maintaining the tumor phenotype. Experiments were performed in R2C LC (R2C), the best known *in vitro* model for Leydigioma. R2C were treated with CAL (10^{-11} M-10^{-8} M). Gene and protein expression were evaluated by RT-qPCR and Western blot, respectively. Cell proliferation was measured by ^{3}H-Thymidine incorporation. CAL (10^{-9} M; 5 h) increased the expression of VDR, histidine decarboxylase (HDC) and HA receptors H1 and H4 genes (p<0.05), but diminished the expression of StAR protein and CYP19 (p<0.05). Also, CAL (10^{-9} M; 24 h) inhibited R2C proliferation (p<0.05). Overall, our results suggest that CAL negatively modulates steroidogenesis and proliferation in R2C, either directly or by favoring the action of HA through H1 and H4, whose selective activation has been reported to inhibit such processes. Although further research is needed, CAL treatment should be considered as a potential therapeutic strategy in LCT.

Garrahan", Combate de los Pozos 1881 (C1245 AAM) C.A.B.A., Argentina.

Leydig cell tumors (LCT) are rare endocrine tumors of the testicular interstitium, with recent increased incidence. Symptoms include precocious puberty in children; and erectile dysfunction, infertility and/or gynecomastia, in adults. The evidence so far points to aromatase (CYP19) overexpression and excessive estrogen (E2) and IGF–1 production as responsible for Leydig cell tumorigenesis. While LCT are usually benign, the malignant phenotype in adults responds poorly to chemo/radiotherapy, highlighting the need to identify new targets for treatment. Herein, we studied the potential role of the histamine receptor H4 (HRH4) as a therapeutic target for LCT. Experiments were performed in R2C rat Leydig tumor cells (R2C), the best-known *in vitro* model for Leydigioma. The expression of HRH4, StAR and CYP19 was evaluated by qPCR and Western Blot. P4 and E2 levels were quantified by RIA, and cell proliferation was determined by ^{3}H-Thymidine incorporation. *The angiogenic capacity of R2C and the effect of HRH4 agonist treatment on this capacity* were evaluated *in vitro* and *in vivo*, using human umbilical vein *endothelial cells* and by means of the quail chorioallantoic membrane assay, respectively. Also, HRH4 immunoexpression was studied in 2 human LCT *versus* normal human testis samples (NHTS) belonging to four different age groups: neonatal, n=2; infantile, n=1; juvenile, n=3 and pubertal, n=3. E2 and IGF-1 negatively regulated HRH4 mRNA and protein levels in R2C. In agreement, HRH4 expression was weak in LCT but moderate to strong, and confined to the interstitium, in all the NHTS analyzed. No HRH4 was detected in seminiferous tubules or germ cells. Treatment of R2C with HRH4 agonists inhibited StAR expression (p<0.01), P4 and E2 synthesis (p<0.01), CYP19 expression (p<0.05), and cell proliferation (p<0.001). Finally, selective HRH4 activation negatively affected the angiogenic capacity of R2C (p<0.001). Overall, our results point to HRH4 as a novel therapeutic target in LCT.

Resistance to corticosteroids in patients with severe asthma and with chronic obstructive pulmonary disease (COPD) is an important barrier to an effective treatment. Different lines of evidence indicate that glucocorticoids (GCs) resistance is the result of significant changes in the cellular microenvironment that occur over time during disease progression. Several factors have been involved in this process and recent findings indicate that miRNAs may also be playing a role in the development of GC resistance during chronic inflammatory states. In this work we contribute to the characterization of the immunoendocrine interactions observed in patients with both severe asthma and COPD as a preliminary approach to subsequent studies on the role of sRNA in the development of GC resistance in these diseases. Both sputum and blood samples from volunteers (n=20) were employed to compare the events occurring at the lung with what happens in the peripheral compartments. As expected, most asthmatic patients, and some with COPD showed abnormally high IgE blood levels and mild leukocytosis, with elevated eosinophils. Interestingly, in most cases sputum cytology did not show an eosinophilic infiltrate and neither of these findings correlated with the severity/stage of the diseases. Levels of endogenous cortisol were also quantified to confirm that there is no adrenal suppression in these patients despite treatment with inhaled corticosteroids. Also, RNA was purified from both sputum and blood samples and CG receptor transcript and miR-223, let-7 and tRNAh Glu were quantified by RT-qPCR, being able to detect sRNAs in all analyzed samples, including extracellular fractions. In summary, these results provide a first approach for the better understanding of the immunoendocrine alterations associated with pulmonary obstructive diseases and present a useful experimental design for the study of regulatory mechanisms mediated by miRNAs in secretions of patients with asthma and COPD.

Keywords: asthma, COPD, sRNA, glucocorticoids

(764) **HYPOGONADISM IN MEN WITH STABLE CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD). ASSOCIATION BETWEEN TESTOSTERONE AND COPD SEVERITY. CROSS SECTIONAL STUDY**

Sebastián Matías Suárez (1), Pablo René Costanzo (1), Pablo Knoblovits (1), Joaquín Maritano Furtada (1), Juan Arturo Precerutti (1), Horacio Matías Castro (1)

(1) Hospital Italiano de Buenos Aires.

The prevalence of hypogonadism in patients with COPD is estimated in 22-69%. The association between testosterone (T) levels and COPD severity is controversial. Aim: To estimate the prevalence of hypogonadism in men with stable COPD and the association between T and COPD severity. Methods: 47 men, 69.1±8.9 years and BMI: 27.8±4.3 kg/m^2 were included. COPD severity was evaluated with BODE index. Laboratory: total T(TT), estradiol (E2), LH, SHBG and prolactin.Free (FT) and bioavailable T (BT) were calculated. ADAM and IIEF-5 score were performed. Hypogonadism was considered when TT<3 ng/ml, FT<6.1 ng/ml or BT<1.2 ng/ml. Results: Laboratory (X±SD): TT 3.3±1.3 ng/ml, FT 5.4±1.8 ng/ml, BT 1.2±0.4 ng/ml, LH 4.2±2.1 mU/ml, SHBG 46.1±18.8 nmol/l, E2 24.9±7.4 ng/ml and prolactin 8.2±3.5 ng/ml. Hypogonadism: TT 48.9%, FT 63.8%, BT 42.6%. ADAM score was positive in 80.9% patients, 38.3% in those with TT>3 ng/ml and 86.7% in those with TT<3 ng/ml. IIEF-5 was performed in 28 patients, 82.1% had erectile dysfunction. A negative correlation between BODE index and TT: -0.28, p=0.05; FT: -0.38, p=0.007 and BT: -0.39, p=0.0065, was found. Conclusions: Men with stable COPD have a high prevalence

of biochemical and clinical hypogonadism. ADAM score has a high sensitivity and a low specificity, T measurement is recommended. T values have a negative correlation with the severity of COPD, lower T are associated with high severity.There is a high prevalence of erectile dysfunction in this population.

Key words: hypogonadism, chronic obstructive pulmonary disease

(1399) **HYPERCOAGULABLE STATE AND RISK OF TROMBOSIS IN THE DOG WITH CUSHING'S DISEASE**

Patricia Noemí Vidal, Diego Daniel Miceli, Víctor Alejandro Castillo
Facultad de Cs. Veterinarias - Hospital Escuela de Pequeños Animales - UBA, Unidad de Endocrinología.

Hypercoagulable state is a situation of high morbidity and mortality in the dog with Cushing's Disease (EC). The most serious condition is pulmonary thromboembolism which is a cause of death. D-dimer (DD), a degradation product of fibrin, is an indicator of thrombosis. The Von Willebrand Factor (FvW) and the inhibitor of plasminogen activator-1 (PAI-1), are increased in plurimetabolic syndromes. The objective of this study was to evaluate whether the activity of Antithrombin III (ATIII) and DD are useful as indicators of formation or presence of thrombosis and to analyze the concentrations of FvW and PAI-1 in the dog with EC compared to a group of healthy dogs. We studied a total of 26 dogs with EC. To make the comparison 12 of them were taken and then 12 dogs from the bioterior, as a control group. All patients underwent platelet counts, coagulation times (KPTT and prothrombin time (PT)), fibrinogen (F), ATIII expressed as ATIII activity (normal> 80%) and DD (positive> 200, DD +). FvW and PAI-1 were measured by ELISA. Proteinuria in relation to creatinine (PRC, normal value <0.30). Results were expressed as average ± SEM, the comparison of the averages were made by the t-test of unpaired samples. P <0.05 was considered significant. Fisher's Test was also used. The platelet count, KPTT, TP and F were normal. In 9/26 (34.6%) both the ATIII and the DD were altered, with an inverse correlation (r = -0.5). The PRC was elevated in 10/26 (38.5%), associating with the lowest ATIII activity and DD +, PRC values correlated with ATIII (r = -0.75) and with DD (r = 0, 67). The concentrations of FvW and PAI-1 were significantly higher in the group with EC (FvW: 4,2±0,3 vs 2,7±0,3 ng/ml; PAI-1: 836,6±153,2 vs 295,2±24,1 pg/ml). Routine coagulation studies aren't relevant for diagnosing thrombosis. The increase in FvW and PAI-1 shows the presence of hypercoagulability and higher risk of thrombosis. The evaluation of DD and ATIII is recommended for the diagnosis of thrombosis.

(1355) **COORDINATED REGULATION OF HEPCIDIN AND IRON IMPORTERS THROUGH IRON EXCESS AND ERYTHROPOIETIN SIGNALS IN ENTEROCYTE AND HEPATOCYTES IN MICE MODELS.**

Gisela Giorgi, Florencia Fernandez Delías, Marta Roque
Fisiología Humana. Biología, Bioquímica y Farmacia. Universidad Nacional del Sur-CONICET-INBIOSUR. Bahía Blanca.

The erythropoietic activity is the main inhibitor of the hepcidin expression, the key regulator of the iron metabolism that reduces the intestinal absorption of iron and the release from macrophages. **Objective:** To evaluate the response of functional axis "HEPCIDIN-DMT1-ZIP14 using mice models of iron-overload and also an erythropoiesis induced by EPO. **M*aterials and Methods*:** CF1 mice (25±5g) were divided into 4 groups (n=4/group;block design):1)*Iron-overload and* erythropoietin(IO+EPO) Fe-Saccharate ip (days 0,4,8,12;1800mg/kg) and EPO ip(days 17,18,19;20000UI/kg);*2)Iron-overload*(IO);3)Erythropoietin(EPO);4*)control (C).*The Protocol was approved by the Committee on Experimental Animal Use and Care-UNS. Immunohistochemistry: DMT1, ZRTIre like protein14 (ZIP14),prohepcidin,ferritin. **Results:** *Duodenum:* In control and EPO, ZIP14 was found in enterocytes apical membrane, while a slight basolateral expression was seen in iron-overload with and without EPO. DMT1 in enterocyte cytoplasm was moderated in Control, while in Iron-overload it was slight. In EPO and IO+EPO, the apical DMT1 was intense. *Liver:* The prohepcidin expression was slight in EPO, moderated in control and intense in IO and IO+ EPO. Both ZIP14 and ferritin in hepatocyte cytoplasm were weak in C and in EPO, they were intense in iron-overload and IO+EPO. Evident DMT1 expression was detected in the cell membrane and in cytoplasm of hepatocytes in EPO, while a weak expression was observed in C. In IO+EPO and IO, DMT1 expression was slight in hepatocytes cytoplasm. **Conclusions:** Two signals could induce specific response for each group: (i) *iron-signal,* induced prohepcidin synthesis**,** which reduced the duodenal iron uptake through DMT1 and ZIP14 and increased the hepatic iron storage through ZIP14, reducing iron availability; (ii) *EPO-signal,* which affected duodenal iron uptake by DMT1 and, therefore, allowed an iron supply to the bone marrow.

Key words: erythropoiesis, iron-overload, mice models, enterocytes, hepatocytes.

(1393) **PROTEINS ASSOCIATED TO UPTAKE OF IRON IN HUMAN NEUROBLASTOMA CELLS**

Florencia Fernandez Delías (1), Gisela Giorgi (1), Daniela Vittori (2), Marta Roque (1)
(1) Fisiología Humana. Biología, Bioquímica y Farmacia. Universidad Nacional del Sur-CONICET-INBIOSUR. Bahía Blanca. (2) Universidad de Buenos Aires, Facultad de Ciencias Exactas y Naturales, Departamento de Química Biológica. CONICET-IQUIBICEN.

Introduction: Alterations in the neuronal iron uptake are frequently associated to brain diseases. Therefore, the aim was to study the effect of iron excess on divalent metal transporter1 (DMT1) and Zrt-Irt-like Protein14 (ZIP14) expressions in human neuroblastoma cells. Materials and Methods: To evaluate cellular viability a dose-response curve was assayed with low and high iron concentrations (ferric ammonium citrate-FAC) 30μM-80μM and 200μM-600μM, respectively at different times. The iron uptake was assessed in the culture medium in 30μMFAC/72hs and in 600 μM/24hs treatments. Pre-treated cells with NAC 2Mm/12hs plus FAC30μM/72hs for immunocytochemistry: DMT1, ZIP14, prohepcidin, ferritin. Viability was assessed by a nuclear red method. Iron levels: Wiener kit. Results: In treatments with low FAC concentrations (30μM, 60μM and 80μM) it was observed a decrease in cellular viability at 72hs ($p<0,05$). However, in treatments with high FAC concentrations (450μM and 600μM), the decrease in the cellular viability was seen at 24hs($p<0,05$). The iron content in the culture medium decreased by 25% in 600μM-24hs and by 42% with 30μM/72 hs treatments. The ZIP14, prohepcidin and ferritin expressions were higher in cells with FAC 30μM/72hs compared with those found in the control. The DMT1 immunoreactivity was lower in cells with FAC30μM/72hs than that observed in the control. The NAC pre-treatment reversed the change induced by the iron in the ZIP14, the prohepcidin and the ferritin expressions. Conclusions: The increase in the ZIP14 expression could reflect a high iron uptake that produced neuronal death, being DMT1 the transporter without a relevant role. The high prohepcidin expression could suggest a decrease of iron export through deregulation of axis hepcidin-FPN. Thus, the change of the ZIP14 expression in neurons could be one of the mechanisms that produce neuronal death by high iron uptake.

(440) **ASSOCIATION BETWEEN GENOMIC REARRANGEMENTS AND INSTABILITY IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA**

Micaela Palmitelli (1, 2), Flavia Stella (2), Andrea Kryzswinski (2), Irma Slavutsky (2), Marcela Gonzalez Cid (1, 3)
(1) Laboratorio de Mutagénesis. (2) Laboratorio de Genética de Neoplasias Linfoides, Instituto de Medicina Experimental, CONICET-Academia Nacional de Medicina. (3) Instituto de Medicina Experimental, CONICET-Academia Nacional de Medicina.

Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with a highly variable clinical course. Genomic instability (GI), evidenced by acquired genetic aberrations, has an important role in CLL pathogenesis, as the number of genomic alterations was shown to increase throughout the course from newly diagnosed to progressive and further to relapsed CLL. GI can be assessed by means of chromosome aberrations (CA) and micronucleus (MN) analysis. Cytogenetic and FISH (fluorescence in situ hybridization) studies are important prognostic factors in CLL. We have analyzed GI in 81 untreated CLL patients (41 males; mean age: 65.6 years; range: 42-83 years) and 6 normal controls. Cytogenetic analysis was performed on stimulated peripheral blood lymphocyte cultures. FISH was performed using the CLL panel according to manufacturer's protocol. For each patient, CA was evaluated on 50 metaphases while 250 interphase nuclei were analyzed for MN frequency. An increased number of CAs in CLL patients compared to controls (6.89±5.4% vs 0.25±0.4%, p=0.004), with the higher value in cases with abnormal (8.54±5.8%) vs normal (5.2±4.5%) karyotype (p=0.008), was observed. Considering FISH risk groups, the analysis showed a higher frequency of CA in patients with deletions 11q22/17p13 (8.4±5.6%) associated to poor prognosis than those with no alterations or deletion 13q14 (5.1±3.8%) (p=0.012) related to a better outcome, and +12 (3.6±2.3%) with intermediate risk (p=0.010). MN analysis displayed an increased frequency in CLL patients (3.1±1.7%) compared to controls (0.7±0.3%) (p=0.001) but no significant differences between cytogenetic or FISH groups were observed. Our results show the presence of basal genomic instability in untreated CLL patients as measured by both CA and MN techniques, as well as an association with cytogenetic and FISH risk groups, being to our knowledge the first study taking into account these prognostic factors.

Keywords: chronic lymphocytic leukemia, genomic instability, FISH, cytogenetic analysis.

(1232) **CANONICAL AND NON-CANONICAL STIMULATION OF T-ALL TUMOR CELLS AND MESENCHYMAL STROMAL CELLS DETERMINES TUMORAL NICHES WITH DIFFERENTIAL BEHAVIOR**

Mariana Amoros (1), Florencia Cayrol (2), Luciana Gutiérrez (1), Juan Bayo (3), Ricardo Farias (4), Leandro Cerchietti (5), Mariana Garcia (3), Carlos Luzzani (6), Santiago Miriuka (6), Alejandro Correa (7), Graciela Cremaschi (2), Marcela Bolontrade (1)

T-cell acute lymphoblastic leukemia (T-ALL) constitutes 20% of diagnosed ALL. As other hematological tumors it presents a close connection with the stromal counterpart. Leukemia cells can adjust the niche affecting the communication between the stroma and HSC in models of T-ALL. Thyroid hormone (TH) modulation may be critical in determining cancer progression. In this context we investigated the acquired functional behavior of mesenchymal stromal cells (MSC) when regulated by T-ALL cells in a TH-modulated microenvironment. We demonstrated that TH stimulation on T-ALL cells via surface receptors (non-canonical TH action) induced a higher chemotactic response and stronger morphogenic rearrangements, while canonical TH stimulation on tumor cells induced less chemotactic response (1.5 fold higher, 148±23 MSC/field, p<0,05) and less morphogenic rearrangements in MSC. Further, direct stimuli exerted by canonical TH on MSC induced higher MMP2 activity (1,55±0,25 vs. 1,24±0,15 MMP2 relative activity, p<0,01) and a high secretory activity via microvesicles (MV) on these cells (0,44 ug/ml/cm2 vs. 0,3 ug/ml/cm2). We proposed based on the outlined data a working model where canonical TH stimulation generates a niche that induces MSC to stay and rearrange the tumor microenvironment, while non-canonical TH stimulation generates a tumor microenvironment with MSC more prone to leave the niche. Thus, signaling triggering a prevailing canonical or non-canonical TH action could be critical in determining a tumoral niche of T-ALL cells interacting with MSC.

(885) **SMC3 HAPLOINSUFFICIENCY RESULTS IN GERMINAL CENTER HYPERPLASIA AND COOPERATES WITH BCL6 TO INDUCE B-CELL LYMPHOMA**

Martín Rivas (1), Matthew Challman (1), Cem Meydan (1), Wendy Beguelin (1), Ashley Doane (1), Aaron Viny (2), Ross Levine (2), Ari Melnick (1)

The cohesin complex is a multiprotein complex composed of four core subunits, being Smc3 a unique subunit that cannot be replaced by any other protein. We recently showed that in the germinal center, B cells undergo a massive reorganization of chromosomal architecture, with the cohesin complex preferentially localizing in those new interactions. In the present work we aimed to identify the role of cohesin during GC B cell development. We used a conditional knockout mouse model for Smc3 with Cre excision controlled by Cg1 or CD19 genes. Complete knockout of Smc3 resulted in abrogation of GC formation, as evidenced by flow cytometry and immunohistochemistry (t test, p<0.001). Curiously, excision of only one allele of Smc3 resulted in hyperplasia of GC (t test, p<0.001). Since the cohesin complex is known to regulate chromosomal folding and promoter-to-enhancer interaction, we performed HiC in sorted GC from wild type or Smc3 haploinsufficient mice. We observed that cohesin haploinsufficiency caused a mild but consistent decrease in long range interactions in the order of 100 Mb. No changes in gene expression or overall chromatin accessibility were observed, nor major changes in enhancer and promoter usage between wild type and Smc3 haploinsufficient GC B-cells. However, Smc3 haploinsufficient GC B-cells had a larger S-phase duration and a higher mutational load. To address If GC hyperplasia translated into differential lymphomagenesis, we crossed Smc3 mice to ImBcl6 mice, which develop lymphoma over time, and we observed that Smc3/Bcl6 mice developed lymphomas faster and more aggressively than any othergroup (Long-rank test, p<0.001). Our results provide evidence for an Smc3 role during GC development and demonstrate that alterations of the cohesin complex can create vulnerabilities leading to malignant transformation in conjunction with known oncogenes.

(1070) **ANALYSIS OF *MYC* REARRANGEMENTS IN PATIENTS WITH MULTIPLE MYELOMA**

Leticia Giselle Guasch (1), Flavia Stella (1), Miguel González (2), Estela Pedrazzini (1), Irma Slavutsky (1)

(1) Laboratorio de Genética de Neoplasias Linfoides, Instituto de Medicina Experimental, CONICET-Academia Nacional de Medicina, (2) Servicio de Oncohematología, Instituto de Investigaciones Hematológicas, Academia Nacional de Medicina.

Multiple myeloma (MM) is a malignant B-cell lymphoproliferative disease characterized by the infiltration of clonal plasma cells in the bone marrow. At the genetic level, it is a heterogeneous disorder characterized by multistage accumulation of genetic abnormalities deregulating different pathways. The *MYC* proto-oncogene is a transcription factor that plays a role in cell cycle progression, apoptosis and cellular transformation. Rearrangements of this gene have been thought to be rare events in MM. In this study, we have evaluated *MYC* rearrangements in MM patients by FISH (fluorescence in situ hybridization) analysis. A total of 46 MM patients (26 females; mean age: 59.5 years; range: 46-86 years) were analyzed. Cytogenetic study was performed on unstimulated bone marrow cultures. FISH analysis was performed using TP53, RB1, IGH and MYC probes (Live-Lexel, Argentina) according to manufacturer´s protocol. *MYC* rearrangements were observed in 25 (54.3%) patients: 19 (76%) cases showed split signals, 5 (20%) had *MYC* gains and one case (4%) showed both split and gain. The correlation with recurrent alterations detected by FISH revealed a significant association with the presence of IGH rearrangements (p<0.007). Although no significant differences were found, the analysis taking into account chromo-

some alterations showed a higher frequency of *MYC* rearrangements in cases with normal karyotype (28%) compared to those with abnormal karyotype (9%). The evaluation according to the International Stage System (ISS) found higher frequency of *MYC* alterations in cases with ISS 2 and 3 (45%) than in ISS 1 (37.5%). No association with the other clinical parameters was observed. The high prevalence of *MYC* rearrangements in MM patients of our series indicates the importance to perform this study in order to refine the prognostic evaluation and treatment decisions. To our knowledge, this is the first analysis of these alterations in Argentinean MM patients.

Key word: Multiple myeloma; *MYC* rearrangements; FISH

(595) **DETERMINATION OF ALLELE BURDEN OF JAK$_2$V617F MUTATION IN GENOMIC AND PLASMA CELL FREE DNA IN MIELOPROLIFERATIVE NEOPLASMS**

Maria Alejandra Cardozo, Luisa Gaydou, Adriana Follonier, Verónica Bozquiazo, Jorge Guillermo Ramos
Facultad de Bioquimica y Ciencias Biológicas

Cell free DNA (cfDNA) in plasma has the clinical potential to be a more specific tumour marker for diagnosis and prognosis, as well as for early disease detection. Currently, determination of the JAK $_2$ V617F mutation and measurement of its allele burden (AB) is performed in genomic DNA (gDNA) using both peripheral blood (PB) and bone marrow (BM) samples from patients with chronic myeloproliferative neoplasms (MPNs). With this procedure, not all malignant alleles could be detected. In this work we compared the %AB of JAK$_2$V617F (percentage of alleles JAK$_2$V617F / total alleles JAK$_2$) in gDNA and cfDNA samples using a quantitative rel time PCR methodology. For quantification we used a calibration curve made with a mixture of gDNA from healthy individuals and gDNA derived from a homozygous JAK$_2$V617F-Human-erythroleukemia cell line (ATCC Hel 92.1.7). JAK2 status mutation was analyzed in 10 patients with MPNs, primary and secondary myelofibrosis (MF) [n: 4], Escential thrombocytosis (ET) and Policitema Vera (PV) (n: 6), which were diagnosed according to the 2008 World Health Organization (WHO) classification. gDNA was obtained from peripheral blood using a modified Miller and Dykes technique, while cfDNA was obtained from plasma using the QIAmp DNA Blood Mini kit. We showed a highly significative correlation between the %AB of JAK$_2$V617F in cfDNA and gDNA (Spearman P=0.0028). Also, when we analyzed paired samples, we observed a higher %AB in cfDNA (P=0.001) compared to the gDNA compartment. These data show that plasma is enriched with tumour-specific nucleic acid and could be the sample of choice for testing JAK$_2$ mutations.

Keywords: JAK $_2$V617F mutation, chronic myeloproliferative neoplasms, cell free DNA

(437) **METHYLATION OF TUMOR SUPRESSOR GENES P15, P16, RARβ2 AND SOCS1 PROMOTERS IN LEUKEMIA PATIENTS**

Lucas González, Eugenio Cálcena, Verónica Martínez Marignac, Lucrecia Longarzo, Alejandro Bolzán, Silvina Richard
IMBICE, CONICET-CCT, La Plata

DNA methylation plays a critical role in the transcription regulation. Its increase, mainly in promoter genes regions, generates a reduction or transcription blockage in patients with different types of cancer. It has been found that some tumor suppressor genes are hypermethylated (inactive). This could be a factor leading to the progress or malignancy of this disease. In this work we propose to study the methylation profile of 4 tumor suppressor genes (CDKN2B (p15INK4b), CDKN2A (p16iNK4a), RARβ2 and SOCS1) in 30 patients with acute myeloid leukemia and chronic myeloid leukemia (16 AML and 14 CML) and in 30 controls samples by the methylation-specific PCR technique, MSP, with previous treatment of DNA with sodium bisulfite, for the conversion of unmethylated Cytosines into Uracil bases. We analyzed 25/30 patient samples and 26/30 controls. Significant correlations in patients methylation status ($p < 0.05$) were found in p16 and SOCS1 gene's promoters by Fisher's test analysis. We found 40% (8 methylated + 2 hemimethylated) and 48% (5 methylated + 7 hemimethylated) in p16 and SOCS1 respectively. No methylation was found in p15 gene promoter neither patient analysis nor in control samples. Finally, RARβ2 shows that 36% of the patients analyzed, contain partial methylation (hemimethylation) in their promoters, which could mean a decrease in their expression. These results suggest that methylation in the promoters of the p15INK4b and SOCS1 genes could be related to the events that generate the onset or progression of the disease. The silencing by hemimethylation in the promoter of the RARβ2 gene would lead to a decrease in its expression, which could generate effects that favor the process of leucemogenesis.

(717) **EUGENOL AS AN ALTERNATIVE FOR THE MANAGEMENT OF COMMON CARP (*Cyprinus carpio*)**

Victor Salina (1), Guillermo Fermín Prieto (2), Carlos Alberto Errecalde (2), Miguel Mancini (1), Natalia Urzúa Pizarro (2), Maria Paula Tonini (2), Jimena Messina (2)
(1) Acuicultura, FAV, UNRC. (2) Farmacología, FAV, UNRC.

Common carp (*Cyprinus carpio)*, has been introduced in different parts of the world. Is adapted to different culture systems and is the specie of greater world production. These systems expose fish to neuroendocrine and physiological changes affecting productive performance and survival; which are reduced with the use of depressants. The objective of the work, carried out in La Helvecia shallow lake (Córdoba), was to evaluate in *C. carpio* the activity of eugenol, an agonist of GABA, at different concentrations. Fish were randomly collected from a batch of 100 housed in a 5 cubic meter cage located within the lake, forming 2 groups of 10 fish (A: 134.0±21.1 g, 23.8±1.8 cm and B: 116.0 ±26.4 g, 23.0±2.3 cm). Three containers of 50 liters each were used to avoid acclimatization stress. Concentrations were 25 and 50 ppm for groups A and B respectively. The work sequence consisted in: a) acclimatization of fish in a container to register basal respiratory rate after adopting normal swimming behavior; b) transfer to the second container with eugenol, recording times of partial balance loss, lateral decubitus, reaching anesthesia, presence of excitation and respiratory rate in anesthesia, c) placed in a third container to control behavior and recovery. Data were analyzed using the non-parametric Mann-Whitney test. Results indicates that eugenol exerts a significant effect on the respiratory activity, decreasing from 106.4±5.7 to 84.4±7.6 and 107.8±12.5 to 68.0 ±12.9 opercular movements per minute ($P < 0.05$) at 25 and 50 ppm respectively. Differences were observed in achieving anesthesia, demanding 5.5 ±1.0 minutes at 25 ppm and 2.4±0.5 minutes at 50 ppm ($P < 0.05$) and total recovery time: 3.7±0.8 and 6.5±1.5 minutes for 25 and 50 ppm respectively ($P < 0.05$). No fish had signs of excitation, no deaths were recorded 96 hours after the study. Preliminary results show eugenol as a good alternative for the management and anesthesia of *C. carpio* under natural conditions.

Key words: *Cyprinus carpio*, eugenol, anaesthesia

(1695) **RELATIONSHIP BETWEEN SEVERITY OF PERIODONTAL DISEASE AND RHEUMATOID ARTHRITIS CLINICAL MANIFESTATIONS**

Teresita Ferrary (1), Lis Bianchi (1), Noelia Sanchez Ratto (1), Cristina Calvano (1), Mariana Armada (1), María Belén Benitez (1), Ariel Gualtieri (1), Margarita Landi (2), Betina Orman (1)
(1) Facultad de Odontología. UBA. (2) IREP

Periodontal disease (PD) is a pathological inflammatory condition leading to the destruction of the soft and hard tissues and eventually to tooth loss. PD is initiated by a bacterial infection that spreads immune systemically and has been associated with the raised risk of systemic diseases such bacterial pneumonia, cardiovascular heart disease, stroke and autoimmune diseases. Rheumatoid arthritis (RA) is a progressive and chronic, inflammatory autoimmune disease associated with articular and systemic effects although the etiology of RA remains unknown. RA progression and severity are influenced by genetic, environmental and infection factors. RA clini-

cal presentation can be of erosive and nodular presentation. RA and PD share analogous pathological features. Little is known about the prevalence of both inflammation diseases in Argentina. The **objectives** are to investigate the prevalence of periodontal disease in RA patients in Buenos Aires, Argentina and the relationship between the severity of PD with RA clinical expression (erosive and nodular). **Materials and Methods**: 111 patients with RA were included. Clinical evaluation and radiological studies were performed. Presence and severity of periodontal disease (attachment level, pocket depth and bleeding index) was assessed. Control 101 people from the general population without RA**. Results:** RA patients have a higher prevalence of severe periodontal disease compared to controls (12,2% vs 7,4%, p=0.002). PD is found in both arthritis presentations (nodular and erosive). The erosive presentation of RA is predominant in patients with mild (45%) and moderate PD (51%). The percentage of patients presenting both clinical manifestations increases with the grade of the severity of PD, reaching 42% of patients with severe PD. **Conclusion:** this is the first approach that investigates the relationship between the presence of erosive and nodular RA with the severity of the periodontal disease that showed a positive correlation.

Words: Periodontal disease, Rheumatoid arthritis, erosive, nodular

(1602) **KNOWLEDGE THE STUDENTS WHO ARE CURSING GENERAL PHARMACOLOGY HAVE ON MEDICINAL PLANTS PHARMACOLOGY CATHEDRAL - FCM – UNC**

Maria Susana Hernandez Caffot, Carlota Grigorjev, Marcela Diez, Lucia Nuri Ponce, Nilda Brizuela
Catedra de Farmacología - FCM - UNC

The consumption of medicinal plants has increased considerably in recent years. It is important to take precaution in the use of them because it is not advisable to self-medicate even if, in general, they are considered harmless. Objectives: To evaluate students' knowledge of medicinal herbs. Determine if training is needed during the grade. Materials and Methods: Prospective, descriptive, cross - sectional study carried out in August 2017 in students who were in the 3 year course of Medicine - FCM - UNC Cát. Of General Pharmacology. We used a previously validated survey which was random, anonymous, voluntary, semi-structured with general sociodemographic and specific data referring to medicinal plants, the degree of acceptance and use. The sample was 246 out of a total of 647 students. Within the study population 162 (65.9%) were women and 84 (34.1%) were men. The most frequent age range was 20-21 for both women and men. Results: There is no knowledge about medicinal plants 127 students (52%). They did not consume medicinal plants 153 (62.2%). They believe that 185 (75.2%) are effective, although they do not consider them as 181 (73.6%). Regarding knowledge about their indication, they indicated that: from Poleo 190 (77.2), Ambay 223 (90.7%) and Cola de Caballo 192 (78%) were unaware of their indication, Aloe 160 (65%) antiulcerous, Manzanilla 101 (41.1%) sedante. The responses of the herbs that can be used in pregnancy were incorrect in 68.8% of the respondents. They do not know if they have interactions with other drugs 134 (54.5%) and consider training on medicinal herbs 217 (88.2%) necessary. Conclusions: A high percentage of those surveyed stated that they did not know about medicinal herbs. Most believe that they are effective but do not consider them safe. Due to the results obtained and, to the interest shown by the students, the incorporation of these contents in the subject is considered.

(193) **ESTABLISHMENT OF CELLULAR MODELS DERIVED FROM A BILATERAL PATIENT WITH RETINOBLASTOMA**

Ursula Andrea Winter (1), Rosario Aschero (2), Santiago Zugbi (1), Mariana Sgroi (3), Claudia Sampor (4), Fabiana Lubieniecki (2), Adriana Fandiño (3), Guillermo Chantada (4), Paula Schaiquevich (1)
(1) Hospital de Pediatría J.P Garrahan, Unidad de Farmacocinética Clínica. (2) Hospital de Pediatría J.P Garrahan, Servicio de Patología. (3) Hospital de Pediatría J.P Garrahan, Servicio de Oftalmología. (4) Hospital de Pediatría J.P Garrahan, Servicio de Hemato-Oncología.

Retinoblastoma (RB) is the most common intraocular cancer in children. Previous research groups have built cells lines modeled after RB patients in developed countries, but there has never been cell lines derived from a patient who was enucleated upfront from both eyes(naïve)**.** Therefore, our research focused on developing cell lines that are modeled after a naïve patient which can later be used for translational research.

Intraocular tumor samples taken by the ophthalmologist at the time of enucleation were used to make the cell culture. After the cell culture was established, evaluations were made to assess the origin of the cell using different types of lineage specific markers includingdiasylganglioside GD2,arrestin3 (ARR3) and synaptophysin by immunohistochemistry and the expression of cone-rod homebox (CRX) through RTq-PCR.Double time (DT) was also calculated. Pharmacological characterizations were made by the determination of theconcentration of drugs that inhibit 50% of the cell viability (IC50) using melphalan, carboplatin and topotecan. The study protocol and informed consent were approved by the Institutional Committee Review board (Protocol #N662).

We established two cell models derived from a bilateral patient with RB: one from the left eye tumors and one from the right eye tumors.Both cell models expressed GD2 and synaptophysinillustrating that they derived from a neuroectodermal tumor. Also, both cultures expressed ARR3 and CRX demonstrating that the cultures were indicative of retinal progenitor cells. The culture derived from the right eye was observed to be growing more slowly (DT=4.5 days) than the one derived from the left eye (DT=3.4 days). However, there was no significant difference observed between the IC50 for all three drugs between both eyes (p>0.05).

Altogether, we were able to develop an effective cell models. These models may be useful to understand the progression and tumor development in a bilateral patient and in other preclinical models.

Keywords : Retinoblastoma, cell models, naïve, bilateral.

(82) **EVALUATION OF DRUG-DRUG INTERACTIONS IN CATTLE USING INTESTINAL EXPLANTS**

Adrian Lifschitz, Vanina Perez, Mariana Ballent, Paula Viviani, Carlos Lanusse, Guillermo Virkel
Centro de Investigación Veterinaria de Tandil (CIVETAN) (UNCPBA-CICPBA-CONICET), Facultad de Cs. Veterinarias, Tandil, Buenos Aires

The concurrent administration of drugs is currently used in veterinary medicine. In cattle, the coadministration of anthelmintics may be a useful pharmacological tool to delay the parasite resistance. Different transporter proteins such as P-glycoprotein (P-gp) are involved in the excretion process of anthelmintics. Previous studies corroborated *in vivo* pharmacokinetic changes obtained after the coadministration of two macrocyclic lactones. The aim of the current trial was to evaluate the modulation of intestinal transport of macrocyclic lactones in cattle using the intestinal explants model. Bovine ileum samples from Aberdeen Angus/Hereford crossbreed steers were obtained from a slaughterhouse located in Tandil area. Immediately following sacrifice, a segment of caudal ileum (30 cm) was opened by the mesenteric border, rinsed with ice-cold 1.15% KCl and immersed in ice-cold Euro-Collins solution containing abamectin (ABM) alone (0.5 μM) or ABM plus ivermectin (IVM) (1μM). Containers were covered, chilled in ice, and transported to the laboratory within 30–40 min for subsequent procedures. Intestinal explants (19 mm of diameter) were prepared and transferred to 6-well culture plates with 6 ml of Wiliams´ medium E inside a container with a humidified atmosphere of 95% O2:5% CO2 at 37 ºC. Intestinal explants were harvested between 15 and 60 minutes post-incubation and frozen at -20 ºC. ABM concentrations were measured by HPLC with fluorescent detection. The concentrations of ABM in the explants were significantly higher after the coincubation with IVM ($P<0.05$). ABM accumulation in the intestinal explants was 2.3 fold higher at 30 minutes post-incubation with IVM. The ABM accumulation rate during the 60 minutes of incubation was 50 % higher in the presence of IVM. As was previously corroborated *in vivo*, the intestinal explants were a useful model to evaluate the drug-drug interaction between macrocyclic lactones in bovine.

Keywords: intestinal explants, cattle, drug-drug interactions, P-glycoprotein

(747) **FLUOROQUINOLONE DEPLETION IN EDIBLE COMPARTMENTS OF EGGS IN LAYING HENS**

Carlos Alberto Errecalde (1), Guillermo Fermín Prieto (1), Natalia Urzúa Pizarro (1), María Paula Tonini (1), Romina Gramaglia (1), María Emilia Errecalde (1), Rosendo Liboa (2)
(1) Farmacología, FAV, UNRC, (2) Bromatología, FAV, UNRC

Fluoroquinolones are antimicrobials approved for use in domestic animals but are not allowed in laying birds because they generate residues in eggs that compromise food safety, although they are usually applied against infectious diseases that defy animal life. This study was performed to establish depletion in the edible compartments of the egg. Laying hens in postural peak were used, divided into two groups, group A (N = 15) and B (N = 10) receiving 7.3 and 1.5 mg / kg of danofloxacin (DFX) and marbofloxacin (MFX) respectively in the drinking water 5for 11 days. At the end of the administration, eggs were collected daily and separated into clear and yolk. In group A the extraction of the analyte was performed with 200 µL of sample, 200 µL of water, 800 µL of a solution of methanol: water: perchloric acid 50: 50: 2 v / v / v and norfloxacin as internal standard and in group B with methanol: water: perchloric acid: phosphoric acid (50: 50: 2 v / v / v) and enrofloxacin as internal standard.The whole was centrifuged 25 minutes at 13500 rpm at 4 ° C. Separation and quantification was performed by HPLC reverse phase isocratic elution with C-18 column, fluorescence detector at λ_{ex} 295 nm and λ_{em} 490 (DFX) and 500 nm (MBX) and mobile phase composed of water, acetonitrile and triethylamine (79: 19:1 v/v/v) at pH 3. Using peak areas of known concentrations, the concentrations of test samples were calculated by simple linear regression. According to the complexity of matrix studied, the procedures applied are simple, fast and sensitive for monitoring programs and control of residues. Levels that declined significantly after the second day were established, and persists until 9 and 15 (DFX) and 8 and 9 days (MBX) in clear and yolk, respectively, Being more relevant in yolk according to the liposolubility of fluoroquinolones and the time required by each egg compartment for its formation, according to the extension of the treatment.

Key words: fluoroquinolones, eggs, disposition

(996) **NEW UHPLC-MS/MS METHOD FOR THE IDENTIFICATION OF BENZNIDAZOLE AND REDUCTION METABOLITES IN BIOLOGICAL FLUIDS**

Carlos Alberto Pérez Montilla, Daniela Marisa Rocco, Facundo García Bournissen.

Benznidazole (BNZ) is the drug of choice for the treatment of Chagas' disease, but its metabolism and elimination have never been studied in depth. The aim of this study was to develop the methodology required for BNZ metabolism studies, using liquid chromatography linked to mass spectrometry (UHPLC-MS/MS). A new UHPLC-MS/MS method was developed for the rapid identification of BNZ, reduction metabolites like aminobenznidazole (BNZ-H2) and hydroxyaminobenznidazole (BNZ-HOH), and their glucuronidated forms (BNZ-OH-Gluc) and (BNZ-H-Gluc), in biological fluids. Spectrometric parameters were optimized by direct infusion of a BNZ-Water:Acetonitrile solution in an *ABSciex QTRAP 6500* triple quadrupole mass spectrometer. After optimizing the mass spectrometry parameters, the chromatographic conditions were optimized by injecting 3 µL of the BNZ solution through a C18 Shim-Pack XR-ODSII column 75 mm long, 3 mm internal diameter and 2.2 µm particle size, on a Shimadzu Nexera X2 UHPLC, coupled to the spectrometer using electrospray ionization in positive mode. Once BNZ identification was optimized, we proceeded to study urine samples from BNZ-treated Chagas' disease patients. Samples were extracted in acetonitrile and centrifuged, and the supernatants injected in the UHPLC-MS/MS system. BNZ and its reduced derivatives were detected and characterized using enhanced mass scans (EMS), Q1-Multiple Ion, enhanced product ion (EPI) and MS3 modes, whereas glucuronic acids were recognized by the neutral loss of glucuronic acid (+176 m/z) in neutral loss mode (NL), in conjunction with EPI and MS3. The method developed enables the five compounds to be monitored in 3 minutes by the *MRM Scheduled Scan* mode with high reliability, based on their transitions and characteristic chromatographic times. This method could allow rapid identification and exploration of BNZ metabolites in patients, an especially useful tool in the follow-up of pediatric patients treated for Chagas' disease.

Keywords: UHPLC-MS/MS, benznidazole, aminobenznidazole, glucuronides, MRM-*scheduled*.

(555) **HYPERGLYCOSYLATED IFN-ALPHA2B MUTEINS WITH IMPROVED PHARMACOKINETIC PROPERTIES AND HIGHER *IN VIVO* ANTITUMOR ACTIVITY**

Agustina Gugliotta, Natalia Ceaglio, Marina Etcheverrigaray, Ricardo Kratje, Marcos Oggero
UNL, CONICET, FBCB, Cell Culture LaboratoryLaboratorio de Cultivos Celulares., Ciudad Universitaria UNL. Pje. "El Pozo". Santa Fe, Argentina.

IFN-alpha2b is a pleiotropic cytokine that has been used for the treatment of many viral and tumor diseases. Its pharmaceutical relevance has inspired the development of many new IFN-based drugs. IFN4N constitute a hyperglycosylated IFN-alpha2b that was developed in our laboratory by glycoengineering strategies. This new molecule exhibited reduced *in vitro* antiviral and antiproliferative activity compared to the non-glycosylated IFN. However, IFN4N showed improved pharmacokinetic properties as well as higher *in vivo* antitumor activity. Since the mutation R23N has been identified as the main responsible of affecting IFN4N antiproliferative capacity, here we propone the design, production, purification and characterization of new highly glycosylated IFN-alpha2b muteins with better *in vitro* and *in vivo* biological activity.

Different groups of muteins have been designed and produced in CHO-K1 cells in order to reach the goal. Group A involves IFN variants with the same amount of potential glycosylation sites but higher *in vitro* antiproliferative activity compared to IFN4N. Group B presents muteins with higher glycosylation degree but lower *in vitro* activity (R23N mutation is present). Group C combines the best mutations in new muteins that exhibited improved *in vitro* antiproliferative activity as well as higher glycosylation degree. Two muteins of each group were purified in order to analyze their pharmacokinetic properties in Wistar rats. The result showed that the higher the apparent molecular mass, the slower the plasmatic clearance. *In vivo* experiments, performed in nude mice implanted with prostate cancer derived cells, revealed that the new hyperglycosylated variants were able to reduce the growth rate of the tumors. Particularly, their weight at the end of the treatment was significantly reduced for muteins belonging to group A and C, compared to the control.

Our results show the importance of pharmacokinetics as well as *in vivo* antitumor activity in order to improve the performance of IFN-alpha2b as a biotherapeutic.

(254) **INTESTINAL PERMEATION OF NEW ZIDOVUDINE PRODRUGS DESIGNED TO OPTIMIZE BIOPHARMACEUTICAL PROPERTIES**

Mario Alfredo Quevedo, Esteban Martín Schenfeld
Unidad de Investigación y Desarrollo en Tecnología Farmacéutica (UNITEFA-CONICET)

Zidovudine (AZT) is an anti-VIH drug widely used to treat AIDS. Despite its clinical efficacy, AZT presents variable and low bioavailability which in turn result in severe adverse effects. The present work reports the intestinal permeation studies using a *ex vivo* intestinal gut sac technique of four new AZT derivates: AZT-Suc-Fen-O-met (**1**), AZT-Suc-Iso-O-met (**2**), AZT-Glu-Fen-O-met (**3**), AZT-Adi-Fen-O-met (**4**), designed to enhance the bioavailability and protein binding properties of AZT.

In a first stage, a bioanalytical method was developed and validated to quantify AZT and the studied prodrugs prodrugs in TC199, with the corresponding chemical stability being also evaluated. In a next stage, the intestinal permeation of AZT and **1-4** was evaluated in proximal jejunum, at two concentrations (0.45×10^{-5} M and 1×10^{-5} M) in the presence and absence of the Pgp inhibitor Verapamil.

The results showed that the magnitudes of the apparent permability (P_{app}) was **3<2<1<4**. The P_{app} of **4** is not statistically different to that of AZT (p >0.05), while the rest of the derivativves exhibited a less overall permeability compared to AZT AZT (p< 0.05). In particular, compound **1** permeated by passive diffusion and was not subjected to Pgp mediated efflux, while **2** permeated by passive diffusion and was subjected to Pgp efflux. Respect to **3**, this derivative presented a low permeability and a high efflux, while prodrug **4** presented the highest intrinsic permeability among the studied compounds and was also able regenerate AZT by metabolism inside the enterocyte.

In conclusion, in this study we report four new AZT derivates that exhibiting different absorption mechanisms. In particular, the prodrug **4** presented a similar overall permeability to that observed for to AZT without being subject to Pgp efflux. These findings constitutes a significant advantage for the design of new prodrugs able to optimize AZT biopharmaceutical properties.

Keywords: Intestinal permeation, AZT, prodrugs.

(997) **NATURAL TREATMENTS: LACTOFERRIN EXERTS ANTIGIARDICIDAL EFFECTS THROUGH STRESS AND CRITICAL MORPHOLOGICAL DEFECTS**

Lorena Frontera (1), Adriana Lanfredi Rangel (2), María Carolina Touz (1)
(1) Instituto de Investigación Médica Mercedes y Martín Ferreyra-INIMEC-CONICET_UNC, (2) Centro de Pesquisas Gonçalo Moniz, FIOCRUZ-BA, Brazil.

Understanding how parasites respond to mechanisms of cellular stress is necessary to identify essential processes on their life. *Giardia lamblia* is a protozoa parasite that is the most common cause of non-viral non-bacterial diarrheal disease world-wide. Despite the effectiveness of metronidazole, a major antigiardial drug, its strong side effects has been matter of concern. Consequently, the search for natural treatments is important for the control of the illness. Glycoprotein bovine lactoferrin (bLF) and its peptide lactoferricin (bLFcin), have exhibited antimicrobial activity in *Giardia*. However, there is little evidence of the underlying mechanisms for their effect. Thus, our goal was to understand how these molecules are internalized and how their microbicide mechanism beyond cell death takes place. To address this point, we performed uptake experiments and different fluorescence and electron microscopy techniques. Our results showed that both molecules are internalized by receptor-mediated endocytosis and are localized in the endo-lysosomal compartments. By transmission and scanning electron microscopy, we observed that both bLF and bLFcin produce morphological changes correlated with the trigger of ER stress. Moreover, trophozoite treatment leads to a partial encystation process probably as a consequence of the general stress induced in the cell. Our findings reinforce the knowledge of a safety use of lactoferrin as treatment for giardiasis.

(1925) **TEGUMENTARY LEISHMANIASIS, KNOWLEDGE AND SOCIAL BEHAVIOR OF THE TARGET POPULATION**

Stella López, Victoria Fragueiro Frias, Vanesa Negri, Adelina Riarte.
Instituto Nacional de Parasitología "Dr. Mario Fatala Chaben" (INP) ANLIS C.G. Malbran. Buenos Aires. Argentina.

Leishmaniasis are caused by trypanosomatid protozoans of the genus Leishmania spp, transmitted by sandflies. The different species of Leishmania cause a wide spectrum of manifestations: L Tegumentary (LT) that can be cutaneous, or mucous, and visceral. Leishmaniasis has a high public health impact due to its morbidity and mortality and is associated with environmental factors and anthropogenic modifications.

The INP receives samples from different health centers for the diagnostic confirmation of leishmaniasis, as a National Reference Laboratory.

We did an exploratory study based on interviews among those who attended the INP for diagnosis in 2016. Socio-demographic data, knowledge, preventive practices and perception of the disease were obtained. Results: 14 men and 8 women were interviewed with an average age of 40 years. They came from Paraguay, 5; NEA, 5; NOA, 3; BsAs, 5; Sta Fe 1; Bolivia, 1; Peru, 1; Senegal, 1. They lived 13/22 in GBA and 9/22 performed rural tasks. Low knowledge about LT was detected; 5/19 recognize or have heard speak; 2 knew the form of transmission and recognized the vector 13/22 recognized the "polvorín, mosquita, carachay, zancudo", mainly those of Paraguay and Misiones: People avoided insect bites by covering limbs (6), repellent (13) use of mosquito nets (5) and fume at home and peridomicilio (10). The lesions are mainly found on mucosa (8) and extremities (6). Some patients remember the prime infection in their youth, more than 20 years ago. Most do not consider LT a serious or contagious disease. In the social aspect they do not perceive a differential relationship between family and friends. However some, due to exposed lesions had modified the dress and avoided the concurrence to spaces of social encounter. At the time of the interview 8/22 they were under sick leave. Conclusion: They recognize the vector from their common names, especially those who lived in NEA, Paraguay and did rural work. The results show little knowledge of the disease and the prevention measures seem to have been insufficient. The need appears to provide accessible and easily understood information for a medical consultation, a quick diagnosis and a timely treatment.

Key Words: Leishmaniasis Tegumentaria- Social Knowledge and Behavior

(661) **THE TLR AGONIST PROFILIN PROTEIN FROM *TOXOPLASMA GONDII* GENERATES PROTECTION IN AN EXPERIMENTAL VACCINE**

CESyMA-UNSAM

Toxoplasmosis is a disease that affects 30% of the world's population. At present, there are no pharmacological treatments that eliminate the parasite or vaccines that confer protection to the host. In this work, we studied the adjuvant and/or immunogenic value of a recombinant form of *T. gondii* Profilin protein (rTgPF), a TLR ligand, in a vaccine strategy using a murine model of chronic toxoplasmosis. BALB/c mice were intradermal immunized 3 times with a 2-week interval with: rGRA7 (recombinant *T. gondii* dense granule 7 protein), rTgPF, rGRA7+rTgPF or rGRA7+ACF.The anti-GRA7 humoral response showed a Th1 profile when rTgPF was used as adjuvant (IgG1/IgG2a ratio: 0,6±0,5), while rGRA7+ACF showed a mixed profile (IgG1/IgG2a ratio: 1,3±0,5). Splenocytes from rGRA7+rTgPF and rGRA7+ACF mice stimulated with rGRA7, showed similar levels of proliferative responses that were significantly higher than the control group (p <0.05), and also significant production of IFN-γ (p <0.05 vs control). In addition, although rTgPF generated a low humoral response, this presented a Th1 profile both in rTgPF and rGRA7+rTgPF groups (IgG1/IgG2a ratio: 0,4±0,1 and 0,4±0,1 respectively). After rTgPF *in vitro* stimulation of splenocytes, significant proliferative responses and also significant production of IFN-γ were detected in rGRA7+rTgPF mice compared to the control group (p<0.01). When vaccinated mice were orally challenged with a non-lethal dose of *T. gondii* cysts, rGRA7+rTgPF mice presented a 62% reduction in the cysts number per brain compared to the control group (p<0,05). This reduction resulted similar to the observed for the rGRA7+ACF group. Together these results demonstrate the dual role of rTgPF: as an adjuvant with capacity to enhance immune responses against another antigen, and also as an immunogen given its ability to induce specific responses. We conclude that Profilin is a valuable candidate to include in a vaccine against toxoplasmosis

Key words: Toxoplasma gondii, Vaccine, Chronic infection, Profilin, GRA7

(848) **TARGETING PROTEIN A DURING STAPHYLOCOCCUS AUREUS OSTEOMYELITIS**

Maimonides, (4) INIGEM.

Staphylococcus aureus is a major causative agent of osteomyelitis in adults and children. The increasing incidence of antimicrobial resistant isolates and the morbidity of this type of infection denote that alternative therapeutic approaches are required. We have recently demonstrated that staphylococcal protein A significantly contributes to increased osteoclast differentiation and activation as well as cortical bone destruction during the course of disease. Therefore, we hypothesize that targeting protein A in addition to antimicrobial treatment could be an adjunctive strategy to control bone damage during the initial course of S. aureus osteomyelitis. The aim of this study was to evaluate the potential of using anti-protein A antibodies to neutralize the deleterious effect of this protein on bone homeostasis using and in vivo experimental model of osteomyelitis. Groups of BALB/c and C57BL/6 mice received anti-protein A antibodies by intraperitoneal route (75 mg/kg) or normal rabbit serum (sham control) one day before the subsequent challenge with S. aureus (2 x 106 UFC) in the left tibia. Two days later the tibias were excised and the bone marrow cells collected and cultured in the presence of M-CSF (50 ng/ml) to obtain osteoclast precursors. Immunization with anti-protein A antibodies significantly reduced the priming of osteoclast precursors in response to S. aureus infection as evidenced by their decreased capacity to differentiate into mature osteoclasts after in vitro stimulation with RANKL (BALB/c: p<0,01; C57BL/6: p<0,001). Moreover, administration of anti-protein A antibodies on day -1, 6 and 9 after S. aureus challenge significantly decreased the levels of IL-1, IL-6 and TNF-α in the bone at day 14 after the onset of experimental osteomyelitis (p<0,05). These results indicate that anti-protein A antibodies could locally reduce the undesirable effects of S. aureus induced osteoclastogenesis during the initial stages of osteomyelitis.

Keywords: Staphylococcus aureus, osteomyelitis, protein A, osteoclastogenesis, immunization.

(874) **TNFR1 SIGNALING DRIVES THE IMMUNOSUPPRESSIVE FUNCTION OF MDSC DURING *Staphylococcus aureus* SEPSIS**

Camila Ledo (1), Cintia Gonzalez (1), Carolina Poncini (1), Marisa Gómez (2)
(1) Instituto de Investigaciones en Microbiología y Parasitología Médica, (2) Universidad Maimónides.

TNF-α signaling is strongly associated with the inflammatory response that characterizes the initial phase of sepsis. The events that govern the concomitant and subsequent immunosuppression, however, are not completely elucidated. Myeloid derived suppressor cells (MDSC) have been described as an immature population of cells that is able to suppress T cell responses. It has been described that TNF-α participates in MDSC accumulation and activation during chronic inflammation.

The aim of this study was to determine the role of MDSC and TNFR1 signaling in the modulation of T cell function during *S. aureus* sepsis.

We used a murine model of *S. aureus* sepsis of peritoneal origin. At day 8 after inoculation, a significant increase in the percentage of MDSC accumulated in the spleen (p<0,001) and significantly reduced T CD4$^+$ cell responses (p<0,05), measured as the proliferative capacity in response to Con A, were observed in *S. aureus* infected mice compared with control mice. Treatment of septic mice with 5'Fluorouracil, at a dose proven to specifically deplete MDSC, significantly improved the proliferative capacity of CD4+ T cells. Conversely, when *S. aureus* sepsis was induced in *tnfr1*$^{-/-}$ mice, besides a significant increase in the percentage of MDSC in the spleen was observed (p<0,01), the proliferative capacity of T CD4$^+$ cells did not differ from that of control mice suggesting that in the absence of TNFR1 signaling MDSC might lose their suppressive capacity. MDSC are known to exert their suppressive function trough the expression of arginase 1 and iNOS. The levels of *arg*1 and iNOS were decreased in MDSC from *tnfr1*$^{-/-}$ septic mice compared with MDSC from wild type mice. Taken together these results indicate that MDSC contribute to T cell dysfunction during *S. aureus* sepsis and that TNFR1 signaling determines the suppressive capacity of these cells highlighting the role of TNF-α in both, the inflammatory and the immunosuppressive, phases of staphylococcal sepsis.

Keywords: sepsis, immunosuppression, *Staphylococcus aureus,* myeloid derived suppressor cells.

(877) **PHENO AND GENOTYPIC CHARACTERIZATION OF AN *ENTEROCOCCUS FAECIUM* STRAIN AND ITS VIRULENCE IN A MURINE MODEL OF MASTITIS**

Melina Moliva, Ivana Montironi, Noelia Campra, José María Raviolo, Laura Noelia Cariddi, Elina Reinoso
Universidad Nacional de Río Cuarto.

Abstract: Bovine mastitis is a disease that causes significant economic losses to the dairy industry in the world, being streptococci and enterococci the main environmental bacteria involved. The aim of this work was to characterize pheno and genotypically an *Enterococcus faecium* strain collected from a bovine mastitis case. In addition, bacterial counts and histopathological alterations in the mammary tissue were evaluated using a mouse mastitis model. For phenotypic characterization bacteria growth curve, antibiotic susceptibility testing, enterococcal virulence factors and biofilm assays were performed. For genotypic characterization, amplification of virulence associated genes by PCR assays and PFGE assay were performed. The maximum cell growth was determined at 6 h. The strain only showed susceptibility to teicoplanin, presented gamma hemolysin and did not present gelatinase activity. It could be characterized as moderate biofilm producer and yielded *gelE1* and *efa* genes. PFGE analysis showed the presence of 19 bands. Balb/c lactating mice were inoculated as follows: Control: 100 μl of PBS and Group 2: 100 µl of 1x10^{8}CFU/ml of *E. faecium*. Animals were sacrificed 24, 48, 72, 96 and 360 h post-inoculation (p.i.). Bacterial count decreased at 48 hours (p<0.001 with respect to the initial inoculum) and was constant since 72 to 360 h p.i. Group 2 showed an intense infiltration of PMNs since 24 to 96 h p.i and *loss of alveolar* structure *integrity.* The study contributes to the development of experimental intramammary infection model in mice and would facilitate the study of mastitis caused by this pathogen.

Keywords: Enterococcus faecium, mouse mastitis model

(1066) **ROLE OF PROSTAGLANDIN E2 DURING THE HUMAN IMMUNE RESPONSE AGAINST *MYCOBACTERIUM TUBERCULOSIS***

Joaquín Miguel Pellegrini (1), Nancy Liliana Tateosian (1), Agustín Rolandelli (1), Nicolás Oscar Amiano (1), María Paula Morelli (1), Florencia Andrea Castello (1), Alberto Levy (2), Nicolás Casco (2), Domingo Juan Palmero (2), Verónica Edith García (1)

Tuberculosis (TB) is, alongside HIV, the leading cause of death from an infectious disease. In fact, *Mycobacterium tuberculosis* (*Mtb*) causes nearly 10 million of new cases and 1.5 million deaths per year. Prostaglandin E2 (PGE2), an active lipid compound derived from arachidonic acid, is a key mediator of immunopathology in chronic infections and cancer by regulating different stages of immune responses. Manipulation of PGE2 levels was proposed as an approach for countering the Type I IFN signature of TB patients and to alleviate active TB disease, but very limited information exists about this pathway in patients with active TB and the role of autophagy, a cellular process involved in defense mechanism against *Mtb*. Here we investigated the role of PGE2 on modulation of human immune responses against *Mtb*. First, we analyzed the expression of surface molecules that play an important role on T cell activation. Peripheral blood mononuclear cells from healthy donors (HD) and TB patients were cultivated for 16 h without stimulus to allow monocyte adherence. Cells were then stimulated with *Mtb*-Ag ± PGE2 (2 μg/ml) for 24 h or 5 days. Flow cytometry (FC) analysis revealed that PGE2 significantly reduced SLAM and CD31 expression on CD3$^+$ T lymphocytes and CD80 and MHCII expression on CD14$^+$ monocytes from all groups under study. Interestingly, PGE2

reduced the lymphocytes proliferation from HD and TB patients. Besides, autophagy levels were analyzed by FC and Confocal Microscopy against LC3B-II. We found that PGE2 significantly increased LC3 puncta accumulation on monocytes from HD and TB patients. Finally, we observed an interesting increase in apoptotic blebs formation in cells treated with PGE2. Taken together, PGE2 has immunomodulatory features in both innate and adaptive immune responses during human TB. Our findings might contribute to deepen the mechanisms that operate on *Mtb*-resistance mediated by PGE2 and the potential of PGE2 as a tool to improve anti-TB treatment.

(1380) **COMPARATIVE VIRULENCE ANALYSIS OF COMMUNITY-ASSOCIATED AND HEALTHCARE-ASSOCIATED METHICILLIN-RESISTANT Staphylococcus aureus STRAINS CIRCULATING IN ARGENTINA USING THE Galleria mellonella MODEL.**

Danilo Barcudi (1), Gabriela Martino (2), Ana Lía Egea (1), Christian Magni (2), José Luis Bocco (1), Víctor Blancato (2), Claudia Sola (1)

(1) CIBICI CONICET. Fac. de Cs. Químicas, UNC. (2) IBR-CONICET-UNR.

Community-associated MRSA (CA-MRSA) strains are genotypically distinct from healthcare associated MRSA (HA-MRSA), and there is evidence that CA-strains have a more virulent clinical phenotype than HA-MRSA strains causing infection. Nevertheless, in Argentina the behaviour of the circulating strains remains unclear. We aimed to analyse virulence between a representative collection of CA- and HA-MRSA strains recovered throughout Argentina since 1999 in an *in vivo Galleria mellonella* killing model. MRSA were studied by SCC*mec* and spa-typing, PVL, PFGE and MLST. CA-MRSA isolates [I-ST5-IVa t311 PVL^+ (n=2), N-ST30-IVc t019 PVL^+ (n=2) and USA300-ST8-IV t008 PVL^+ (n=2)] and HA-MRSA isolates [A-ST5-I t149 (n=2) and B-ST239-III t037 (n=2)] were analysed. 8 caterpillars were inoculated in triplicate with 5 μl ($6x10^8$ CFU/ml) of each strain and incubated at 37°C and observed every 24 h for 80 h. Log-rank tests were used to compare Kaplan–Meier survival curves for all CA-MRSA vs HA-MRSA strains and for all clonal groups. Statistical analysis showed that CA strains killed more larvae than HA strains ($P<0.001$) and there were no significant differences by CA or HA clones ($P>0.05$). Although, the USA300 clone killed *G. mellonella* larvae more quickly than N or I strains (mean survival time, 47 h for USA300 vs 64 h for N and I strains, P=0.051), there were no significant differences between the CA strains. We also analysed separately the most prevalent CA clones in Argentina (N and I strains), excluding USA300 strains vs. the most prevalent HA clones (A and B strains).This analysis, also showed that CA clones killed more larvae than HA clones ($P<0.018$). These results demonstrate that there are differences regarding virulence in the most prevalent CA- and HA-MRSA strains circulating in Argentina and suggest that the increased virulence phenotype of these clones could be associated with increased killing in *G. mellonella* virulence model.

Keywords: CA-MRSA, HA-MRSA, *Galleria mellonella*

(1560) **EARLY AND RAPID DETECTION OF DENGUE VIRUS SEROTYPES 1–4 BY COLORIMETRIC RT-LAMP AMPLIFICATION ASSAY**

Adrián Vojnov

Dengue viruses (DENV), a member of the Flaviviridae family, are responsible for one of the most important emerging viral diseases. This mosquito-borne disease has a great impact in tropical and subtropical areas of the world in terms of illness, mortality and economic costs, mainly due to the lack of approved vaccine or antiviral drugs. Infections with one of the four serotypes of DENV (DENV-1–4) result in symptoms ranging from an acute, self-limiting febrile illness, dengue fever, to severe dengue haemorrhagic fever or dengue shock syndrome. The aim of this work is to develop an assay for early and rapid detection of DENV infection during the febrile period. An early detection is crucial for proper patient management and prevention of disease spread, especially in the resource-limited rural healthcare settings where dengue is endemic. Here, a specific, sensitive, and robust prototype colorimetric reverse transcriptase loop-mediated isothermal amplification (RT-LAMP) assay was developed for detection and differentiation of DENV1-4 serotypes. These techniques are used as a powerful tool for screening and diagnosis of infectious diseases. This Isothermal method, as an alternative to polymerase chain reaction (PCR), require no thermocycling machine and can mostly be performed with reduced time, high throughput, and accurate and reliable results. The reaction was performed in one step in a single tube by mixing primers, reverse-transcriptase and DNA polymerase together with the tested samples (RNA genome international reference for Dengue serotypes) at 65 □C for 60 min, with the addition visible pH indicator dye prior to amplification. The pH indicator dye change resulting from amplification reactions performed with minimal buffering, by eye without a need for instrumentation. The result showed no cross reactivity to other closely related arbovirus (Zika). Our assay is more sensitive than quantitative reverse transcription-polymerase chain reaction (qRT-PCR).

KEYWORD: Dengue virus, Dengue serotypes 1–4, Diagnostic test, Reverse transcriptase loop-mediated isothermal amplification, Serotype detection.

(1814) **HANTAVIRUS INDUCED CHANGES IN T-CELL SUBPOPULATIONS AND SHOWED UP-REGULATION OF PRO-INFLAMMATORY CYTOKINES RELATED WITH DISEASE SEVERITY**

Ayelen Iglesias (1), Marina Garcia (2), Natalia Periolo (1), Daniel Alonso (1), Pablo Schierlho (1), Jonas Klingstrom (3), Valeria Martinez (1)

(1) Laboratorio Nacional de Referencia Para Hantavirus, Servicio de Biología Molecular, Instituto Nacional de Enfermedades Infecciosas, ANLIS -'Dr. Carlos G. Malbrán', Ciudad Autónoma de Buenos Aires, Argentina. (2) Laboratorio de Inmunología de Enfermedades Respiratorias, Instituto de Medicina Experimental (IMEX)-CONICET-Academia Nacional De Medicina (Anm), Ciudad Autónoma de Buenos Aires, Argentina. (3) Center for Infectious Medicine, Department of Medicine Huddinge, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden.

Hantaviruses are emerging human pathogens. These zoonotic viruses are responsible of two different clinical presentations, hemorrhagic fever with renal syndrome (HFRS) and hantavirus pulmonary syndrome (HPS). Hantaviruses predominantly infect microvascular endothelial cells causing capillary leakage. The hallmark of hantavirus diseases is the vascular permeability, which leads to pulmonary edema in HPS patients. HPS is endemic in Argentina where it was associated to high case fatality rates.

In order to evaluate the role of the immune response on pathogenesis we performed cytokine profile analysis and initial T-cell phenotypic characterization in HPS patients.

For biomarkers analysis we study 109 HPS patients including 39 dead patients (D) and 69 survivors (S). Control samples were obtained from healthy adult volunteers (HV). Serum cytokine and granzyme levels were analyzed using multiplex magnetic bead-based technology by a Luminex 200 analyzer. Fresh blood samples were collected to analyze surface markers on T cell subpopulations by flow cytometry in 19 patients. Statistical analysis was performed by Student's *t*-test using GraphPad Prism 6 software. We found significant higher levels of IL-2, IL-4, IL-6, IL-8, IL-10, INF-γ, GM-CSF and TNFα in patients compared with HV. Interestingly, we showed an increased of Granzyme A and B in patient´s sera compared with HV. Analysis of T cells subsets in patients showed increase in $CD8^+$ cells, resulting in the inversion of the CD4/CD8 ratio compared to HV. This preliminary phenotypic analysis of T cell subpopulations showed an increase of $CD38^+$ /$CD27^-$ in $CD4^+$ and decrease in CD28, CD27 and CD127 in $CD3^+$/$CD8^+$ cells. In addition to this, we observed high number of classic monocytes ($CD14^+CD16^+$) in patients compared with HV. Our results showed a differential biomarker expression according to disease severity. This, together with the preliminary T cell analysis, would suggest an active role of immune response in pathogenesis.

(1917) **HISTOLOGYCAL CHARACTERIZATION OF *Clostridium septicum* TRAUMATIC INFECTION IN MOUSE MODEL**

Sofía Quiroga (1), Rodrigo Alberto Guerra (1), María Julia Divizia (1), María Cecilia Villa (1), Teresa Ines Cortiñas (1), Walter Berón (2)
(1) Area de Microbiología, UNSL. (2) IHEM-CONICET.

Among the main histotoxic clostridia is *Clostridium septicum*, gram positive bacillus, anaerobic and sporulated. It is the causal agent of malignant edema and traumatic gas gangrene in cattle, sheep and goats. Its main virulence factor is the alpha toxin with a necrotizing and cytotoxic activity previously studied in our laboratory that also produces apoptosis. One of the characteristics of this infection is the low number of phagocytic cells at the site of infection. The objective of this work was to evaluate the *in vivo* interaction of *C. septicum* with phagocytic cells in a mouse model. Histological damage was characterized in the muscle infected with pathogen cells and the cell infiltrate was analyzed. A batch of BALB-C mice was inoculated intramuscularly into the hind paw with a DL_{50} of *C. septicum* ATCC 12464 and a 1/10 dilution thereof. After 48 h the mice were euthanized and the legs were surgically removed and embedded in paraffin and stained with hematoxylin-eosin. Inoculation sites in the mice were evaluated by observation of pathological changes in the area The formation of acute or chronic lesions and the infiltration of phagocytic cells at the site of infection were analyzed. The affected animals showed clinical signs at approximately 48 hours after inoculation (depression, muscle swelling, stiffness). The muscular lesion initially presented hyperemic, warm, soft and delimited; and later dark, cold, firm and necrosed. At necropsy serosanguinolent inflammatory fluid was observed in the subcutaneous tissue. In the histopathological examination, necrosis, apoptosis, swelling and vacuolization of muscle fibers were observed. There was edema, hemorrhage, large numbers of bacilli and areas with discrete neutrophil and monocyte infiltration. The ability to eliminate phagocytic cells by both necrosis and apoptosis ways, is an efficient mechanism of evasion of the innate immune system by this pathogen.

(1476) **A TRANSCRIPTOMIC APPROACH TO UNDERSTAND THE STATE DEPENDENCY AND POST ECDYSIS TIME IN THE ANTENNAE OF A CHAGAS DISEASE VECTOR**

Jose Manuel Latorre Estivalis (1), Ewald Grosse-Wilde (2), Sheila Ons (1), Marcelo Gustavo Lorenzo (3)
(1) Centro Regional de Estudios Genómicos, Universidad de la Plata, La Plata (Argentina). (2) Max Planck Institute for Chemical Ecology, Jena. (3) Centro de Pesquisas René Rachou, FIOCRUZ, Belo Horizonte (Brasil)

Abstract: Triatomine bugs transmit Chagas disease to humans in most countries of Latin America. Several authors have clearly established that the behavioral responses of these bugs to host and sexual signals present strong plasticity as a function of the time elapsed since ecdysis. Whether these alterations are based on changes at peripheral or central nervous processes (or both) deserves to be clarified at molecular level to allow better control strategies based on manipulating bug physiology and behavior. A transcriptome of 5th instar larvae antennal samples (seven RNA samples per age point: 0, 2, 4, 6 and 8 days after ecdysis) were sequenced using Illumina HiSeq-2000. The corresponding sequencing results from the 35 libraries were analyzed by means of CLC genomics software. The expression of several chemosensory receptor genes, including odorant, gustatory and ionotropic receptors increased significantly during the first week after ecdysis. Odorant binding and chemosensory proteins presented high antennal expression and some of them increase significantly their transcript abundance after ecdysis. The relevance of these results will be discussed in the context of state dependent behavior.

Keywords: Triatomine, RNAseq, sensory receptors

(1863) **AMERICAN TEGUMENTARY LEISHMANIASIS (ATL) IN YOUNG AGE GROUP IN OUTBREAKS OF THE DISEASE FROM THE PROVINCE OF CORRIENTES**

Maria Josefa Rea, Carlos Edgardo Borda (1), Adrianaines Fleitas (2), Mirta Liliana Mierez (2)
(1) Centro Nacional de Parasitología y Enfermedades Tropicales (CENPETROP), Facultad de Medicina, UNNE. (2) Cátedra de Parasitología, Facultad de Medicina, UNNE.

Leishmaniasis, a parasitic disease transmitted by the bite of some species of sandflies affects various age groups. American tegumentary leishmaniasis (ATL) is caused by different *Leishmania* species ranging from cutaneous forms to severe mucosal lesions.

In America, the observed magnitude of ATL in children has led to the study of increased risk of exposure of this group due to the possibility of peri- and intradomiciliary transmission.

The objective of this study was to describe cases of ATL in children and adolescents in the province of Corrientes, where is endemic.

The diagnostic methods used to confirm the clinical diagnosis: Montenegro Skin Test (MST) and skin smear after MGG coloration.

Thirty-five children and adolescents were diagnosed with ATL in five leishmaniasis epidemic outbreak in the province of Corrientes from 2010-2015.

From the total number of evaluated patients (34), 65% were school-age children (6-12 y-old) and 35% adolescents, of whom 19 (56%) were boys and 15 (44%) girls,

Most of the cases proceeded from the locality of Bella Vista (38%) and from Corrientes city (38%). The rest of localities were: Paso de la Patria, Empedrado and Itatí.

These patients had a mean clinical evolution of 2.9 months of their lesions. Most patients presented just one lesion (86%), which were located mostly in extremities (45% in legs, 19% in arms,11% cases in the face, 13% were in hands). One girl of eight months of age presented one ulcer in the face.

All patients were positive by MST, and 48.8% were positive by smear.

All cases were treated successfully with Glucantime® IM.

Leishmania braziliensis was identified as the main etiological agent of mucosal leishmaniasis in all epidemic outbreak. Infection of *Lutzomyia longipalpis* by *L. amazonensis* was observed in Corrientes city.

Although study participants came mostly from an endemic area, mucosal compromise was rare. A high frequency of LTA was shown in young age groups and cases clustered in urban neighborhoods of Corrientes.

The mass movement of people creates opportunities for the spread and establishment of infectious diseases, such as enteroparasitoses. For both geographical and historical reasons, Gran La Plata is receiving an increasing number of immigrants. We aimed to compare the prevalence of intestinal parasites in immigrant populations (IP) from Bolivia, Paraguay and Peru, and non-migrant populations (NMP**)** resided in periurban of Gran La Plata. A cross-sectional study was conducted between April 2016-July 2017 in two groups of 127 individuals matched for age (0-59 years old) and sex (47.2% males and 52.8% females). Coproparasitological samples were analyzed by Willis and Ritchie concentration methods, anal swabs and conventional PCR. Furthermore, socio-environmental factors were surveyed through semi-structured questionnaires. The overall prevalence of intestinal parasites was 82.7% in IP and 66.1% in NMP (χ^2=9.1,p<0.05). However, the Sørensen's Coefficient showed

a similar parasite species composition in both groups (90%). In IP, *Blastocystis* sp. was significantly more prevalent than NMP (66.9% vs 40.1%) (χ^2= 18.3,p<0.05). We also identified a higher prevalence of *Giardia lamblia* (23.6% vs 17.3%) and *Enterobius vermicularis* (29.9% vs 25.2%) in IP respect to NMP. *Chilomastix mesnili* only was observed in IP and *Ascaris lumbricoides* only was presented in NMP. The multiple infections was more common in IP (21.3% vs 15.0%). In both, socio-environmental data revealed that the most of population did not have access to public services; most of adults had incomplete primary education and did not have stable employment. In contrast, most of IP were not house owners, raised animals for consumption and had hygienic practices more adequate. Although the prevalence of intestinal parasites in IP was higher than NMP, the species composition was similar. Thus, the socio-environmental conditions in both populations adversely affect the parasite transmission.

Chagas disease affects about 7 million people worldwide and is caused by the protozoan parasite *Trypanosoma cruzi*. In the argentine Chaco, an endemic area of Chagas disease, little is known about *T. cruzi* domestic and wild transmission cycles. Therefore, a field trial in rural areas near Añatuya, Santiago del Estero, for eco-epidemiological purposes, is under way. Due to the large number of samples we estimate to obtain in the trial, our goal was to develop a TaqMan multiplex PCR assay that simultaneously allowed *T. cruzi* detection and DNA integrity control. To achieve this, we choose the interphotoreceptor retinoid-binding protein (IRBP) gene, because it is highly conserved in all mammals and its use as a DNA integrity control in a conventional PCR was previously described. Based on an IRBP sequence alignment of several domestic and wild species, we designed a TaqMan probe to a highly conserved region within the amplified zone. The detection of satellite *T. cruzi* DNA was performed with the primers and probe already developed in our laboratory. Once the parameters for the multiplex PCR were established, the assay was tested in a total of 45 blood samples of wild mammals. So far, all samples analyzed were *T. cruzi* undetectable. Our DNA integrity control worked well for *Conepatus chinga, Molossus sp, Lagostomus maximus, Lycalopex gymnocercus, Rattus rattus, Calomys sp, Galea musteloides* and *Leopardus geoffroyi*. However, it did not work for *Chaetophractus villosus, Tolypeutes matacus, Graomys chacoensis* and *Myotis sp*. DNA integrity was tested by amplification of beta-actin in these cases. A sequence analysis to identify mutations that prevent amplification of the selected IRBP region in these species will be done. The performance of the multiplex PCR in domestic animal samples remains to be studied.

Keywords: Chagas disease, *Trypanosoma cruzi* wild and domestic reservoirs, TaqMan Multiplex PCR

(917) **DISTRIBUTION OF POTENTIAL SCHISTOSOMIASIS HOST SNAILS ALONG THE URUGUAY RIVERS BASINS ARGENTINA, IN THE PROVINCE OF CORRIENTES**

Maria Josefa Rea, Carlos Edgardo Borda
Centro Nacional de Parasitología y Enfermedades Tropicales (CENPETROP) y Cátedra de Parasitología, Facultad de Medicina, UNNE

Schistosomiasis is an important neglected tropical disease caused by parasitic worms of the genus *Schistosoma*, with a significant socioeconomic impact. The only species of *Schistosoma* that occurs in the Americas is *S. mansoni* and the transmission occurs largely in Brazil, affecting million people. Natural transmission of schistosomiasis does not exist in Argentina. The distribution of the *S. mansoni* is determined by the presence or absence of *Biomphalaria* snails, which act as the parasite's intermediate host.

This study aims to access the relative abundance and the natural infection of *Biomphalaria straminea* and *B. tenagophila* by *S. mansoni* from seven Department in the Uruguay River basin.

The survey collections were made from March 2015 to September 2016 from different suitable snail habitats. Live snails were kept at the laboratory in aquaria for to identify species and for the screening of positive snails. Snails that did not produce cercariae, were crushed for the search for *S. mansoni* larval stages.

Freshwater snail specimens were collected in different sampling sites in all Department surveyed.

The following species were identified: *B. tenagophila, B. straminea* and *B. orbigny*.

B. tenagophila was the most frequent species, as it was observed in 17 districts of six Departments: five places of Paso de los Libres, five from Mercedes, four from Monte Caseros, two from Curuzú Cuatiá and one from General San Martín

B. straminea was identified in Santo Tomé and *B. orbigny* in Mercedes.

No specimens of collected snails were found infected with *S. mansoni*.

The World Health Organization (WHO) has emphasized the need to create predictive maps for expected schistosome distributions.

Among the *Biomphalaria* species that occur in Brazil, three are regarded as intermediate hosts of *S. mansoni: B. glabrata, B. tenagophila* and *B. straminea*.

The present study extended the geographical distribution of *B. tenagophila* in the Province of Corrientes.

Keywords: *Biomphalaria,* schistosomiasis mansoni, Provincia Corrientes

(1648) **Epidemiology of American Tegumentary Leishmaniasis in the northern province of Salta during the year 2016**

Rubén Cimino, Pamela Cajal, Marisa Juarez, Nicolás Caro, Maria Canabire, Andres Escalada, Marcelo Quipildor, Alejandro Krolewiecki
Instituto de Investigaciones de Enfermedades Tropicales (IIET)

Tegumentary leishmaniasis (LT) is endemic in northern Argentina and is caused by parasites of the genus Leishmania sp. Leishmaniasis is considered by the World Health Organization as "neglected disease". In the departments of Oran and San Martin of the province of Salta, the greatest number of annual cases are reported. The Institute for Tropical Disease Research (IIET) of the National University of Salta is the diagnostic center of the region. The objective of this work is to describe the epidemiology of leishmaniasis from all patients with a compatible ulcer who attended the IIET during 2016. A total of 216 patients with ulcers were analyzed. All the smears were searched for amastigotes. The predominant clinical form was cutaneous (94%), while the rest were mucocutaneous (6%). The 57% (123/216) were smear positive. 74% of the cases were male and 26% were female. Regarding the place of origin of the patients, 62% are SRN Oran, 17% H. Irigoyen and 5% of Pichanal, all localities of the Oran department. The rest of the cases (16%) are neighboring departments (San Martin and Rivadavia). The statistics suggest sanitary measures of promotion and prevention of the leishmaniasis to diminish the incidence of this parasitosis.

(1892) **FIRST CASE OF FELINE LEISHMANIOSIS CAUSED BY LEISHMANIA INFANTUM IN ASUNCION, PARAGUAY**

María José Tintel Astigarraga (1), Eva Megumi Nara Penayo (2), Leticia Elizabeth Rojas Vera (2), Raquel Escrihuela (3)
(1) Profesional Independiente. (2) Instituto de Investigación de Ciencias de la Salud (IICS). (3) Veterinaria España.

The aim of this study was to survey Leishmania infection in a cat with inespecific clinical signs. Evaluation by parasitological, serological and molecular methods. A cat from Asuncion, Paraguay, 3 year

old, male, 3.4 kg had apparent Feline Lower Urinary Tract Disease (FLUTD) fever, depression, lethargy, progressive weight loss, dull hair coat, generalized lymphadenopathy, neurological disorders, mydriasis, pale mucous membranes, slow capillary refill time. The cat was negative for feline immunodeficiency (FIV) and feline leukemia virus (FeLV) (Serology test)

The blood count showed thrombocytopenia and hyperproteinemia, liver and kidney function tests showed elevated FAL, ALT and uremia. A fine bone marrow needle was aspirated and myeloid hyperplasia was determined with the presence of Leishmania sp. The immunochromatography (Rapid Test Kit. Korea. Leishmania infantum antibodies) was positive which was confirmed by PCR method by using 13A/13B primers (Rodgers et al 1990) for Leishmania genus identification followed by a PCR with LV-P1/LV-P2 primers (Piarroux et al, 1994) for Complex Leishmania donovani identification. The DNA was purified from bone marrow tissue in order to improve the sensitivity of the test. The PCR conditions were similar as the publications. It has been described subclinical Leishmania infection in cats in the Mediterranean basin countries and also several studies have demonstrated the infectivity of sand fly vectors from a cat. These facts raise the possibility of reservoir host role for this species.

From a clinical point of view, this case reinforces the importance of including leishmaniosis in the differential diagnoses of feline pathology, especially in cats with inespecific clinical signs. Nevertheless, from a public health perspective it is important to clarify whether this animal species is capable of sustaining and spreading L. infantum infection.

(113) **FUNCTIONAL CHARACTERIZATION OF *T. CRUZI* MUCINS IN THE INFECTION OF THE INVERTEBRATE HOST**

Camara Maria De Los Milagros (1, 2), Debora Passos De Matos (3), Camila Centeno (1), Marcelo Gonzalez (3), Fernando Genta (3), Patricia Azambuja (3), Carlos Buscaglia (1)

Trypanosoma cruzi, the etiological agent of Chagas diseases is covered in different glycoconjugates which contribute to parasite protection and to the establishment of a persistent infection. TcSMUG L is a group of genes coding for small *T. cruzi* mucins anchored to and secreted from the surface of replicative, insect-dwelling developmental forms (i.e. epimastigotes). The objective of this work was the functional characterization of TcMUGL mucin family and their role in the infection of *Rhodnius prolixus*. We analyzed TcSMUGL expression levels in different *T. cruzi* strains observing not only differences in expression levels but also in glycosylation patterns. In order to characterize epimastigote mucin function we generated *T. cruzi* strains overexpressing TcSMUGL and TcTSSA (tripomastigote stage mucin) in two different genetic backgrounds CL Brener (high TcSMUGL levels) and Y strain (low TcSMUGL levels and is unable to infect *Rhodnius prolixus)*. Transgenic lines were used to perform in vivo infection assays in *Rhodnius prolixus*. TcSMUGL CL overexpressing parasites presented higher infection rates than control lines. Furthermore TcSMUGL lines belonging to the Y strain were able to stablish the infection in the insect host, presenting high infectivity rates. In order to further characterize mucin function we performed *in vitro* adhesion using different sections of *Rhodnius prolixus* nymph's digestive tract. Our results indicate that TcSMUGL would be involved in parasites adhesion to the posterior midgut, as both transgenic TcSMUGL lines presented 4 times more adhesion percentages than control lines. Finally we performed in vitro lysis experiments with digestive contents observing that TcSMUGL overexpression enhances parasites survival towards stomach and intestinal contents. Together, these data indicate that TcSMUG L mucins are key determinants of the infectivity of *T. cruzi* towards the insect population and, hence, on *T. cruzi* epidemiology

Key words: *Trypanosoma cruzi*, TcSMUGL, *Rhodnius prolixus*

(1210) **URBAN INFESTATION BY *TRIATOMA INFESTANS* IN THE ARGENTINE CHACO: EVALUATION OF A SELECTIVE TREATMENT PROTOCOL**

Marta Victoria Cardinal, María Sol Gaspe, Alejandra Alvedro, Mariano Alberto Laiño, Gustavo Fabián Enriquez, María Pilar Fernández, Ricardo Esteban Gürtler
Laboratorio de Eco-Epidemiología. Universidad de Buenos Aires. Consejo Nacional de Investigaciones Científicas y Técnicas. Instituto de Ecología, Genética y Evolución de Buenos Aires (IEGEBA), Facultad de Ciencias Exactas y Naturales, Ciudad Universitaria, Buenos Aires, Argentina.

Triatoma infestans has increasingly been found in urban areas of the Gran Chaco ecoregion where vector-borne transmission of *Trypanosoma cruzi* still occurs. How to cope with urban infestations in a cost-effective way remains unclear. As part of the longitudinal intervention program "Avia Terai sin Chagas", we assessed house infestation with *T. infestans* in the town of Avia Terai, Chaco, Argentina. The town had last been sprayed with pyrethroid insecticides by the National and Chaco Chagas Programs in 2011-2013 (total, 774 houses). All inhabited (n=1454) houses were visited in February 2016 and manual searches using a flushing-out agent were performed in 412 houses, including those where dwellers reported having seen triatomines, harbored chickens, and in one of every three houses that did not fulfill any of these conditions. *T. infestans* was found in 56 houses located in 27 of the 125 urban blocks. All infested and adjacent houses were sprayed by local vector control personnel using beta-cypermethrin (Chemotecnica) at 50 mg/m^2 in domiciles and a double dose in peridomestic sites. Using a similar survey protocol, the prevalence of house infestation decreased significantly from 13.6 to 2.9% (n=859) in March-April 2017 (Fisher's exact test, $p<0.0001$), whereas block infestation before (21.6%) and after spraying (15.2%) were not significantly different (p=0.33). Eleven blocks and only 6 houses were persistently infested over surveys. Most of the 25 infested houses in 2017 had not been examined (40%) or had been negative for triatomines in 2016 (36%). Most pre- (78,6%) and post- (68,2%) spraying foci occurred in peridomestic structures. Post-spraying house infestation is most likely explained by the existence of unreported, untreated foci within the infested blocks. Our ongoing research efforts are directed to shed light on the cost-effectiveness of alternative treatment protocols, and ensure improved effectiveness, sustainability and local community acceptance.

(1631) **CHARACTERIZATION OF TWO NOVEL *NEOSPORA CANINUM* ISOLATES FROM A DAIRY FARM IN URUGUAY REVEALS GREAT GENETIC DIVERSITY AMONG REGIONAL ISOLATES**

Andrés Cabrera (1), Maria E. Francia (1), Caroline Da Silva (2), Melissa Macias (2), Paula Arevalo (1), Otto Pritsch (1,3), Martina Crispo (1), Federico Giannitti (2), Carlos Robello (1,3)
(1) Institut Pasteur Montevideo, Uruguay. (2) Instituto Nacional de Investigaciones Agropecuarias (INIA), La Estanzuela, Colonia, Uruguay. (3) Facultad de Medicina, UdelaR, Uruguay.

Neospora caninum causes neosporosis, known as the billion dollar disease, due to its estimated impact on the worldwide economy. Bovine neosporosis *is* one of the leading causes of bovine abortion in the world. However, very little is known about the biology of this parasite. The overarching goal of our study is to tailor both diagnostics and prophylactic strategies to the region´s needs by characterizing prevalent strain(s), at the molecular level. To isolate and genotype *N. caninum* in Uruguay, a group of pregnant cows seropositive for *N. caninum* were identified by ELISA, and followed up to term. Six pre-colostrum seropositive asymptomatic calves were euthanized to attempt parasite isolation. Brain samples were processed for identification of infected areas by PCR analysis and histopathology. Infected brain areas were inoculated into IFNγ-KO mice, and two strains of *N caninum* were recovered. Multi-locus microsatellite typing of genomic DNA revealed a unique genetic pattern, distinct from previously reported isolates from the region, and that of European and North American strains. The genetic diversity revealed by these novel isolates suggests that greater genetic diversity exists than previously reported for this parasite, even among isolates from adjacent geographical regions. These findings reflect a situation akin to what

is observed for other prevalent Apicomplexa such as *Toxoplasma gondii*. We are currently exploring the phenotypic implications of this genetic diversity to determine its impact on virulence, vertical transmission and incidence on abortion rates.

CELL SIGNALING 2

(53) ROLE OF WNT/β-CATENIN AND NOTCH PATHWAYS IN RAT CORPUS LUTEUM DEVELOPMENT

Paula Accialini, Andrés Bechis, Griselda Irusta, Diana Bas, Fernanda Parborell, Dalhia Abramovich, Marta Tesone
Instituto de Biología y Medicina Experimental

Wnt/β-catenin and Notch are evolutionarily conserved pathways involved in the regulation of ovarian function. Previous results from our laboratory using XAV939 to inhibit the canonical Wnt pathway demonstrated that Wnt is implicated in ovulation and luteal function. We established that this pathway is involved in luteal progesterone production through the regulation of StAR levels. In addition, this pathway regulates the proliferation and survival of the Corpus Luteum (CL) cells and the luteal vascular development. The objectives of this study were: 1) to confirm our previous results by using another Wnt inhibitor that acts through a different mechanism and 2) to study the effect of hCG on Notch member expression. To this purpose prepubertal eCG-treated rats were injected with either Wnt inhibitor (XAV939 or ICG-001) or vehicle solution (DMSO, Control group) into the bursa of both ovaries the day of hCG administration. Ovaries were collected 48 hours later. CLs from one ovary were isolated by microdissection and used to measure mRNA, total protein or nuclear protein levels. The other ovary was fixed for histological analysis. The level of nuclear β-catenin, which is responsible for transcriptional regulation, decreased after XAV939 administration, as measured by Western blot (control: 1.7±0.04; XAV939: 1.4±0.05; [n=4]; P<0.01). ICG-001 administration produced ovarian cysts (control: 0%; ICG-001: 1.22±0.33%) and decreased the percentage of CL (control: 43.5±4.5% [n=6]; ICG-001: 25.9±1.5% [n=5]; P<0.05), consistent with the phenotype observed with XAV939. In addition, preliminary qPCR experiments showed an increase in the expression of Notch4 receptor and Hes1 (Notch pathway effector) without effect on Notch1 and Dll4 in CL compared to immature granulosa cells. The results observed with ICG-001 strengthen those previously observed using XAV939 as a Wnt inhibitor, while the results obtained by qPCR suggest a differential expression of Notch members in ovarian cells.

Keywords: Corpus Luteum, Wnt, Notch, ICG-001

(805) THE CFTR CHLORIDE CHANNEL REGULATES EGFR LIGANDS EXPRESSION

María Macarena Massip Copiz (1), Mariángeles Clauzure (1), Consuelo Mori (1), Cristian Asensio (1), Ángel Gabriel Valdivieso (1), Tomás Antonio Santa Coloma (1)
(1) Laboratorio de Biología Celular y Molecular Instituto de Investigaciones Biomédicas (BIOMED) UCA-CONICET.

The *CFTR* (cystic fibrosis transmembrane conductance regulator) gene is mutated in the cystic fibrosis (CF) disease. CFTR is a cAMP-activated chloride channel, member of the superfamily of ABC (ATP Binding Cassette) transporter proteins, which functions not only as a regulated chloride channel but also as a signalling molecule modulating different genes. Previously, we found that several genes had altered expression due to the CFTR failure (p<0.05), such as SRC (a tyrosine-kinase which in turn regulated MUC1), MTND4 (a mitochondrial gene encoding a subunit of the mitochondrial Complex I), and CISD1 (a mitochondrial protein encoded in the nucleus with a yet ill-defined function). Hence, the aim of the present work was to determine if a failure in the CFTR activity (or expression) determines a differential regulation in the EGF receptor and its ligands and which are the signalling pathways involved. We use a cellular model consisting of Caco-2 cells (human colon carcinoma epithelial cells) expressing wt-CFTR that were previously selected and cloned after transfections with short hairpin RNA interference (shRNA) directed against different regions of CFTR (CaCo-2/pRS26) or with its control plasmid (CaCo-2/pRSctrl). The results obtained, by real time PCR, suggested that CFTR modulates significantly (p<0.05) the expression of TGF-alpha, epiregulin and amphiregulin but not the EGFR expression. As we observed an important regulation of epiregulin (EREG) ligand by CFTR, we continue to study the possible signalling pathways involved. We observed that both IL-1β and JNK participates significantly (p<0.05) in EREG expression. In conclusion, CFTR channel activity failure or CFTR inhibition regulates the expression of different EGFR ligands possible involved in phenotype changes present in CF-like cells. This work was supported by ANPCYT (PICT 2012-1278), CONICET (PIP 2015-2017 GI 11220150100227CO and PUE 22920160100129CO), and research fellowships from CONICET.

Keywords: Cystic-Fibrosis; CFTR; EGFR

(1039) THE INFLAMMATORY RESPONSE OF RETINAL PIGMENT EPITHELIUM CELLS EXPOSED TO HIGH GLUCOSE CONCENTRATIONS: THE ROLE OF CLASSICAL PHOSPHOLIPASES D

Paula Estefania Tenconi (1, 2), Vicente Bermúdez (1), Gerardo Martín Oresti (1, 2), Gabriela Alejandra Salvador (1, 2), Norma María Giusto (1, 2), Melina Valeria Mateos (1, 2)
(1) Instituto de Investigaciones Bioquímicas de Bahía Blanca (INIBIBB)-CONICET, (2) Depto. de Biología, Bioquímica y Farmacia (DBByF)-Universidad Nacional del Sur (UNS)

Diabetic retinopathy (DR) is one of the main causes of visual dysfunction and blindness in working-age adults. Chronic hyperglycemia, oxidative stress and inflammation are key players in the pathogenesis of DR. The aim of the present work is to study the role of classical phospholipases D (PLD1 and PLD2) in retinal pigment epithelium (RPE) cells exposed to an *in vitro* DR model induced by high glucose (HG) concentrations.

ARPE-19 and D407 human RPE cells were exposed to normal glucose concentration (Control condition or NG, 5.5 mM) or to HG concentrations (16.5 or 33 mM) for 4, 24 or 72 h. To study the role of classical PLDs and the ERK pathway cells were pre-incubated for 1 h with EVJ (VU0359595, 0.15 μM) to inhibit PLD1 activity, with APV (VU0285655-1, 0.5 μM) to inhibit PLD2 or U0126 (10 μM) to inhibit the MEK/ERK pathway, prior to cell exposure to HG. Statistical analysis was performed using ANOVA followed by Bonferroni´s test and p-values ≤ 0.05 were considered statistically significant.

Our results demonstrate that 72 h exposure to HG reduced cell viability and increased caspase-3 cleavage. In addition, HG exposure for 4 h induced early and concatenated events, as PLD, ERK and nuclear factor kappa B (NFκB) activation. NFκB activation induced by HG correlated with the increment in pro-inflammatory interleukins (IL-6 and IL-8) and cyclooxygenase-2 (COX-2) mRNA levels ($p \leq 0.0001$). The effect of pharmacological inhibitors demonstrated that ERK and NFκB activation were dependent on both PLD isoforms. Furthermore, the increment in IL-6 and COX-2 mRNA levels induced by HG was reduced to control levels in cells pre-incubated with both PLD inhibitors. However, the rise in IL-8 mRNA levels was only reduced in cells incubated with the PLD1 inhibitor, EVJ.

In conclusion, our findings demonstrate that PLD1 and PLD2 mediate the inflammatory response of RPE cells exposed to HG, pointing to the potential use of classical PLDs as a therapeutic target for DR treatment.

(957) THE MAGNITUDE OF Ca^{2+} INDUCED Ca^{2+} RELEASE TRIGGERED BY ACTIVATION OF TRPV4 IS DEPENDENT ON THE EXPRESSION OF AQP2 IN RENAL CELLS

Alejandro Pizzoni, Macarena López González, Gisela Di Giusto, Valeria Rivarlola, Claudia Capurro, Paula Ford
Laboratorio de Biomembranas, Instituto de Fisiología y Biofísica "Bernardo Houssay" (IFIBIO). Facultad de Medicina, UBA. Buenos Aires, Argentina.

There is increasing evidence indicating that aquaporins (AQPs) may influence cell signaling by affecting TRPV4, a non-selective Ca^{2+} channel. In a previous communication we described that under TRPV4 stimulation, AQP2 can modulate SK3 (a KCa subtype)

leading to hyperpolarization of the membrane potential. Surprisingly, TRPV4-mediated Ca^{2+} signals were not apparently affected by Vm hyperpolarization. Since other works reported that TRPV4 activation triggers Ca^{2+} induced Ca^{2+} release (CICR) from intracellular stores, the aim of the present work was to investigate if CICR can mask the influence of hyperpolarization on TRPV4-mediated Ca^{2+} influx in AQP2 expressing cells. Using fluorescent probe techniques, we studied intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) in response to activation of TRPV4 (with 4α-PDD, 10 μM) in two renal cell lines expressing (AQP2-$RCCD_1$) or not AQP2 (WT-$RCCD_1$). In addition, we assessed the colocalization between SK3 and AQP2. We found that in both cell lines, TRPV4-mediated $[Ca^{2+}]_i$ signals were unaffected by preincubation with dantrolene (10 μM), an inhibitor of Ca^{2+} release from ryanodine receptors. However, caffeine (5 mM), an inhibitor of Ca^{2+} release from inositol trisphosphate receptors (InsP3R), significantly diminished the response in both cell lines (Area under curve: Wt-Ctrl: 928±77, n=320 vs. Wt-Caf: 478±54, n=107, p<0.001; Aqp2-Ctrl: 971±38, n=255 vs. Aqp2-Caf: 694±77, n=154, p<0.01). Interestingly, the reduction was lower in AQP2 expressing cells (25%) than in WT cells (50%). These results suggest that TRPV4 activation triggers both Ca^{2+} influx and CICR (via InsP3R) in both cell lines. Nevertheless, when the CICR component was abolished, Ca^{2+}influx was greater in AQP2-$RCCD_1$ cells evidencing a higher Ca^{2+} entry probably due to the hyperpolarization observed as an effect of AQP2-SK3 interaction. Additionally, the immunofluorescence studies showed colocalization of AQP2 with SK3 supporting the idea of an interplay between both proteins.

(487) **THE CHLORIDE ANION ACTS AS A SECOND MESSENGER OF THE CFTR ACTIVITY TO MODULATES THE EXPRESSION OF SPECIFIC GENES**

Ángel Gabriel Valdivieso, Mariángeles Clauzure, Consuelo Mori, María Macarena Massip-Copiz, Tomás Antonio Santa Coloma

The impairment of the CFTR channel function leads to several alterations in cystic fibrosis (CF), including as differential gene expression. We have previously demonstrated that the expression of several genes can be modulated by the CFTR activity. However, the signaling mechanisms by which this channel induces the CF phenotype remain unclear. Recently, applying differential display to IB3-1 CF cells cultured under different intracellular Cl^- concentrations ($[Cl^-]_i$), we observed and characterized two Cl^--dependent genes: *GLRX5* (glutaredoxin 5) and *RPS27* (also named metallopanstimulin-1 or ribosomal protein S27). From these results, we hypothesized that Cl^- might act as a second messenger for CFTR signaling. Here, to test this idea, we study *RPS27* mRNA expression in T84 cells (which express wt-CFTR), modulating the CFTR activity by using pharmacological inhibitors. First, we observed that incubation of T84 cells with increasing concentrations of the CFTR inhibitors CFTR(inh)-172 or GlyH-101 determined a progressive increase ($p<0.05$) in the $[Cl^-]_i$ (using the Cl^- fluorescent probe SPQ). The $[Cl^-]_i$ rise was concomitant with a dose-dependent down-regulation ($p<0.05$) of *RPS27*, suggesting that CFTR inhibition produce Cl^- accumulation and that *RPS27* expression can be modulated by the CFTR activity. More importantly, Cl^- behaves as a signaling effector for CFTR in the modulation of *RPS27* expression. In addition, the IL-1β receptor antagonist IL1RN or the JNK inhibitor SP600125, both restored the down-regulation of *RPS27* induced by CFTRinh-172, implying a role of autocrine IL-1β and JNK signaling downstream of Cl^- in modulation of *RPS27*. The results suggest the existence of Cl^--dependent genes and that Cl^- anion might act as a second messenger modulating the expression of specific genes. Supported by PIP 2015-2017, PUE 22920160100129CO and PICT 2012-1278 to TASC and PICT-2015-1031 to AGV.

(1704) **REGULATION OF NUCLEAR FACTOR KAPPAB SIGNALLING BY FK-506 BINDING PROTEIN 52**

Sonia Alejandra De Leo (1), María Fernanda Camisay (1), Gisela Mazaira (1), Mario Daniel Galigniana (1,2), Alejandra Giselle Erlejman (1)
(1) Laboratorio de Biología Celular y Molecular, IQUIBICEN, FCEN, UBA/CONICET. Buenos Aires, Argentina. (2) Laboratorio de Receptores Nucleares, IByME, Buenos Aires, Argentina.

Nuclear Factor KappaB (NF-κB) is key regulator of the transcription of genes involved in cell death, inflammation and invasion. Recently, we have demonstrated that FKBPs (FK506-binding proteins), especially FKBP51 and FKBP52, are able to modulate NF-κB transcriptional activity. The aim of this work is to determine the participation of FKBP52 in different steps of NF-κB signaling and the expression of NF-κB target genes. Thus, we over expressed FKBP52, FKBP52 F130Y (a mutant lacking peptidylprolyl-isomerase activity (PPIase)), or empty vector (control group). Different hallmarks in NF-κB (p65/p50) activation after PMA or TNF-α stimulation were evaluated: total and phosphorylated p65 protein levels and NF-κB inhibitor´s phosphorylation (p-iκB) by Western blot, p65 nuclear traslocation by immunofluorescence, and the expression of NF-κB target genes by real time PCR. After PMA stimulation neither FKBP52 nor FKBP52 mutant transfection showed significant differences in iκB phosphorylation kinetics compared to control, suggesting an iκB independent mechanism. Also, p65 phosphorylation at Ser536 was not altered by overexpression of FKBP52 or FKBP52 F130Y, compared to control. However, basal p-p65 and total p65 were increased after overexpression of FKBP52 vs. control (p<0,001). Furthermore, after TNF-α treatment FKBP52 favored p65 nuclear retention (vs control and FKBP52 F130Y, p<0,05), in accordance with previous results obtained after PMA simulation. The expression of target genes such as MMP-9 and Bax (evaluated by real time PCR) was regulated by FKBP52 in a peptidylprolyl isomerase dependent manner, since overexpression of FKBP52 F130Y resulted in decreased expression of these genes compared to FKBP52 *wild type*. In summary, we propose FKBP52 as a new key regulator of NF-κB target genes expression, evidencing FKBP52´s PPIase enzymatic activity is essential for this regulation.

(306) **PTHrP INDUCES TUMORIGENIC BETA-CATENIN PATHWAY INDEPENDETLY OF WNT SIGNALING IN COLON CANCER CELLS.**

María Belén Novoa Díaz, María Julia Martín, Pedro Carriere, Natalia Calvo, Claudia Gentili
INBIOSUR, Depto. De Biología, Bioquímica y Farmacia, Universidad Nacional del Sur

Abstract: There is evidence that PTHrP is implicated in different cancers such as colorectal cancer (CCR). CCR is the second most common cancer in Argentina, according to data from the National Cancer Institute. Although great progress has been made in the diagnosis and therapy of CCR, the survival rate remains low. It is known that β-catenin is a protein which plays a key role in maintaining the growth and proliferation of CCR. In tumor intestinal cells treated with PTHrP, we previously found that Akt and ERK1/2 signaling pathways are involved in the phosphorylation and subsequent nuclear translocation of β-catenin. The aim of this study was to further investigate the molecular mechanisms involved in these processes induced by the hormone employing two cell lines derived from human colorectal cancer, Caco-2 and HCT116. Results by Western blot analysis suggest that PKC, Src and p38 MAPK signaling pathways modulate the phosphorylation of β-catenin induced by PTHrP. Once in the nucleus β-catenin can bind to transcription factors, such as LEF-1 and TCF family members, promoting the expression of genes such as c-Myc and cyclin D. Immunocytochemistry analysis suggest that PTHrP induces LEF-1 protein expression and also promotes the association of β-catenin with this transcription factor. However, the protein-protein interaction between β-catenin and Transcription factor 7-like 2 (TCFL2/TCF4) observed in basal conditions is not modified by PTHrP at the times studied. These results may be correlated with our previous reports where PTHrP also increases protein levels of cyclin D and c-Myc through ERK1/2. Finally, employing iCRT 14, a specific inhibitor of gene transcription induced by β-catenin, we

found that β-catenin participates in tumor cell proliferation induced by PTHrP. Investigation of the underlying mechanisms for the tumorigenesis of CCR will facilitate the diagnosis and therapy of this disease.

Keywords: PTHrP, colorectal cancer, molecular mechanisms, β-catenin.

(952) **LIPOPOLYSACCHARIDE-INDUCED AUTOPHAGY IN RETINAL PIGMENT EPITHELIUM CELLS**

Vicente Bermudez (1), Paula Estefanía Tenconi (1, 2), Norma María Giusto (1, 2), Melina Valeria Mateos (1, 2)
(1) Instituto de Investigaciones Bioquímicas de Bahía Blanca (INIBIBB)-CONICET, (2) Depto. de Biología, Bioquímica y Farmacia (DBByF)-Universidad Nacional del Sur (UNS)

Lipopolysaccharide (LPS) can reach the retinal pigment epithelium (RPE) in patients with bacterial endophthalmitis. This unusual pathology (consequence of intravitreal injections, trauma, eye surgery, or sepsis) has generally poor prognosis and often leads to vision loss. Our previous studies demonstrated for the first time that classical phospholipases D (PLDs) participates in the LPS-induced inflammatory process in RPE cells. The aim of the present work is to study the autophagy process in RPE cells exposed to LPS.

For this purpose D407 and ARPE-19 human RPE cells were exposed to LPS (25 µg/ml) for 24 and 48 h. Western Blot (WB) and immunofluorescence (IF) assays were performed in order to evaluate LC3II (an autophagosome marker) content and LC3-positive punctate structures, respectively. To study the role of the PLD pathway, cells were pre-incubated for 1 h with selective PLD1 (EVJ or VU0359595, 0.5 µM) or PLD2 (APV or VU0285655-1 0.5 µM) inhibitors prior to LPS addition. Cell viability was measured using the MTT reduction assay. Statistical analysis was performed using ANOVA followed by Bonferroni´s test and *p*-values ≤ 0.05 were considered statistically significant.

Our results demonstrate that in D407 cells LPS reduced cell viability after 48 h treatment ($p \leq 0.001$). LPS also increased LC3II/LC3I ratio and LC3-positive punctate structures after 24 and 48 h exposure ($p \leq 0.05$). An increment in LC3-positive punctate structures was also observed in ARPE-19 cells exposed to LPS. In addition, PLD1 and PLD2 inhibition highly increases LC3II content in LPS-exposed D407 cells with respect to LPS condition. Furthermore, both PLD inhibitors restore cell viability to control condition levels in D407 cells exposed to LPS.

In conclusion, our results show that LPS treatment reduces cell viability and increases the autophagosome marker LC3II in RPE cells. Furthermore, the inhibition of both PLDs restores cell viability, possibly through the modulation of LPS-induced autophagy.

(58) **1α,25(OH)$_2$D$_3$-GLYCOSIDES AND SYNTHETIC 1α,25(OH)$_2$D$_3$ ACTIONS IN CELL CYCLE AND MYOGENESIS OF C2C12 SKELETAL MUSCLE CELLS**

Ana Paula Irazoqui (1), Pablo De Genaro (1), Claudia Buitrago (1), Heini Bachmann (2), Kathrine Bühler (2), Verónica González Pardo (1), Ana Russo De Boland (1)
(1) INBIOSUR (CONICET-UNS). (2) Herbonis AG.

Solanum glaucophyllum leaf's extracts (SGE) enriched with 1α,25(OH)$_2$VitaminD$_3$-glucosides are available for the organism due to the presence of endogenous glycosidases. We have shown that SGE alike 1α,25(OH)$_2$D$_3$ (1,25D) induces myoblast differentiation. In this work, we investigate Akt role in myoblast fusion to form myotubes during differentiation. The fusion index was determine staining C2C2 cells with MitoTracker Red prior fixation, cells were then stained with DAPI, and examined by fluorescence microscopy. We found that the ability of vitamin D compounds, 1,25D or SGE, to induce myotube formation was impaired in presence of Akt inhibitor LY294002. Since Akt inhibitor suppresses myotube formation, we investigate whether Akt participates in the late differentiation marker MHC2b expression founding that its mRNA expression was induced by 1,25D and SGE in an Akt dependent manner. The commitment of myogenic cells in skeletal muscle differentiation requires earlier irreversible interruption of the cell cycle. To evaluate the effect of SGE on the distribution of C2C12 cells into different phases of the cell cycle, we performed flow cytometry assays. The studies showed that SGE, similarly to 1,25D, prompts a peak of S-phase followed by an arrest in the G0/G1-phase, events which were dependent on the MAP kinases ERK1/2, p38 and JNK. Significant differences of the data between control and treated conditions were analyzed by one way-ANOVA followed by Bonferroni test ($p<0.05$) or t-test (*$p<0.05$, **$p<0.01$). Taken together, these results suggest that SGE, as 1,25D, promotes myotube formation through Akt activation and regulates the cell cycle through ERK1/2, p38 and JNK.

Matías Lasala (1), Jeremías Corradi (1), Ariana Bruzzone (1), Carmen Esandi (1), Cecilia Bouzat (1)
(1) Instituto de Investigaciones Bioquímicas de Bahía Blanca, CONICET-UNS.

The α7 nicotinic receptor subunit gene, *CHRNA7*, codes for a subunit that forms the homomeric α7 receptor, which is involved in learning and memory. In humans, exons 5-10 of *CHRNA7* were duplicated and fused to the *FAM7A* gene, given rise to the *CHRFAM7A* gene. The product of the resulting chimeric gene, dupα7, is a truncated subunit that lacks part of the ACh binding site. We here combined cell expression, confocal microscopy, western blot, and electrophysiological recordings in HEK cells to understand the functional role of the dupα7 subunit. We found that cells transfected with dupα7 cDNA express the dupα7 protein but show neither surface binding of an α7 specific antagonist nor agonist-elicited currents. To determine if dupα7 assembles with α7 into functional receptors, we used an α7 subunit carrying mutations in determinants of conductance (α7LC) as a reporter of receptor stoichiometry. Co-expression of α7LC with dupα7 or the reverse combination, α7 with dupα7LC, allowed detection of single-channel openings elicited by ACh, indicating that α7 and dupα7 subunits co-assemble into functional heteromeric receptors. The analysis revealed that a minimum of two α7 subunits is required for forming functional receptors and that activation of the heteromeric receptors occurs through the α7/α7 interface. Our results contribute to the understanding of the functional significance of the partial duplication of the α7 gene.

(1108) **EPIGALLOCATECHIN-3-GALLATE INCREASES THE AFFINITY FOR NA$^+$ IN THE NA,KATPASE**

Elina Malén Saint Martin, Santiago E. Faraj, Mariela S. Ferreira-Gómes, Mercedes Centeno, Juan Pablo F.C. Rossi, Mónica R. Montes, Rolando C. Rossi
IQUIFIB, Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, Argentina.

The kinetics of formation and breakdown of the intermediates involved in the transport of Na^+ is one of the less studied aspects of the Na,K-ATPase reaction cycle. According to the Albers-Post model, binding of 3 intracellular Na^+ to the *E*1 state of the enzyme triggers phosphorylation by ATP in the presence of Mg^{2+} and Na^+ becomes occluded in the phosphorylated intermediate *E*1P. Na^+ is released to the extracellular medium after the *E*1P®*E*2P conformational transition. Occlusion of Na^+ has only been reported in inhibited enzyme, in the presence of oligomycin or Cr-ATP, and in partially proteolized enzyme.

The aim of the present work is to develop a procedure for measuring the kinetics of Na^+ occlusion in the Na,K-ATPase during the normal functioning of the reaction cycle. For this, states with occluded Na^+ need to be rapidly stabilized and isolated.

In this work, we propose to use epigallocatechin-3-gallate (EGCg) as a stabilizing agent (Ochiai et al., 2009, Biochem. Pharmacol., 78:1069-1074) and a rapid-filtration procedure to isolate the species

with tightly bound Na^+.

Experiments were carried out at 25 °C in media with imidazole-HCl 25 mM, pH 7.4, using Na,K-ATPase partially purified from pig kidney. To evaluate the effects of EGCg on the affinity for Na^+, enzyme was incubated with eosin Y in a medium containing RbCl and different concentrations of NaCl and EGCg. The $K_{0.5}$ for Na^+ for the increment in eosin fluorescence decreased as [EGCg] increased. Measurements of tightly bound $^{22}Na^+$ to the Na,K-ATPase in the presence of 100 μM EGCg show that this increment in affinity for Na^+ is compatible with the stabilization of a state containing occluded Na^+. Addition of 100 μM EGCg to the washing solution is sufficient to "instantaneously freeze" the reactions of formation and breakdown of Na^+-bound states during the normal functioning of the reaction cycle.

Our results show that EGCg is a good stabilizing agent for characterizing the steps involved in the transport of Na^+.

Halomonas titanicae KHS3 is a strain isolated from Mar del Plata harbor that is able to grow on aromatic hydrocarbons and displays chemotactic behavior toward them.

Genomic sequencing allowed the identification of 25 chemoreceptor genes. Most of the genes code for proteins with a predicted periplasmic ligand-binding domain and a highly conserved cytoplasmic signaling domain. To identify those chemoreceptors involved in sensing of aromatic compounds, we first looked at their genomic context. We found one chemoreceptor, Htc1, next to genes related to degradation of aromatic compounds. The ligand-binding domain of this receptor was expressed in *E. coli* as a His-tagged protein. The purified protein was subjected to thermal shift assays. In this assay the Tm (melting temperature) of the protein is expected to increase in the presence of stabilizing ligands. Salicylate, 4-hydroxybenzoate and benzoate increased the Tm, among more than 300 compounds present in the screening plates. The binding was confirmed by thermophoresis assays. All three compounds bind to the periplasmic domain of Htc1 with Kds between 80 and 600 μM. Besides, the full-length receptor conferred the ability to control the flagellar movement in response to salicylate when expressed in *E coli*. An *Halomonas titanicae* Htc1 mutant, however, showed only subtle alterations in chemotaxis, suggesting that there is functional redundancy between *Ht* chemoreceptors.

Among other ligand binding domains from chemoreceptor genes that were subjected to thermal shift assays we found another one (Htc2) whose Tm was also increased with salicylate, as well as with malate, malonate and succinate. The binding properties were characterized using isothermal calorimetry (ITC). The C3-C4 dicarboxylic acids bound with high affinities (Kds between 30 and 600 μM), whereas salicylate binds poorly (Kd about 2.5 mM). Full-length cloning and expression for functional characterization in *E.coli* cells and mutant construction are under way.

Polycystin-2 (PC2, TRPP2) is a Ca^{2+}-permeable nonselective cation channel from the Transient Receptor Potential (TRP) superfamily of cation channels. PC2 is encoded by the PKD2 gene, whose mutations are responsible for autosomal dominant polycystic kidney disease (ADPKD). PC2 has been detected in different cellular locations, including the plasma membrane, the endoplasmic reticulum, and the primary cilium. Recent studies from our laboratory determined that a functional PC2 is regulated by changes in external Ca^{2+} concentration that modify the whole cell conductance of wild type LLC-PK1 renal epithelial cells. The stimulatory effect of high external Ca^{2+} on the PC2 currents was mimicked by agonists of the Calcium-Sensing Receptor (CaSR), including spermine, gentamicin, and the calcimimetic R-568. CaSR was also identified by immunocytochemistry, and observed immuno-colocalized with the PC2 channel protein in a manner that depended on external Ca^{2+}. The present study explored the effect of Ca^{2+} and CaSR agonists in the regulation of PC2 single channel currents from isolated plasma membranes from LLC-PK1 cells reconstituted in a BLM reconstitution system. Addition of "external" R-568 (5 μM) activated cation-selective single channel activity by 84 ± 12% ($n = 4$, $p<0.01$) that were inhibited (91.3 ± 1.1% comparing to control condition, $p<0.0001$) by addition of PC2 carboxy-terminus anti PC2 antibody from the "cytosolic" side of the BLM. The data suggest the presence of a functional/(structural?) CaSR-PC2 complex in the plasma membrane of LLC-PK1 renal epithelial cells, in agreement with a regulatory pathway where external Ca^{2+} modulates PC2 channel function. This receptor-channel complex may be part of a regulatory mechanism whose function may help explain the connection between Ca^{2+} signals and PC2 function in the onset of ADPKD.

Abstract: Flavonoids are commonly found in fruit and vegetables and have been reported to reach micromolar concentration in the human blood plasma. These compounds have antioxidant capacity and are related to cancer chemoprotective properties, by triggering apoptosis of malignant cells through the Ca^{2+}–dependent mitochondrial pathway. Some flavonoids, like quercetin inhibit the activity of sarcoplasmic/endoplasmic reticulum Ca^{2+}-ATPase and the plasma membrane Ca^{2+}-ATPase (PMCA), however the mechanism of its effect is not yet defined. PMCA is a calmodulin regulated P-type ATPase that maintains the homeostasis of intracellular Ca^{2+} in eukaryotic cells, coupling the transport of Ca^{2+} with ATP hydrolysis. The aim of this work is to characterize the inhibition of PMCA by quercetin. We measured the Ca^{2+}-ATPase activity in purified PMCA from human erythrocytes and the $[Ca^{2+}]_c$ transport in HEK293T cells culture. Results using purified PMCA show that quercetin inhibits PMCA activity. Quercetin absorption spectra with added magnesium Mg^{2+} show the formation of a quercetin-Mg^{2+} complex. Competitive kinetics with Mg^{2+} has shown that the mechanism of inhibition of quercetin is totally dependent on the concentration of Mg^{2+}. Assays with [γ-^{32}P] ATP indicate that inhibition of the ATPase activity by quercetin led to the increase of phosphoenzyme level (EP), implying that quercetin blocks the dephosphorylation of the pump. The EP formed is sensitive to dephosphorylation by ADP, suggesting a stabilization of the E1P intermediate. To characterize the effect of quercetin at the cellular level we studied its transport in HEK293T cell culture by measuring the intrinsic quercetin fluorescence. On the other hand, PMCA activity in HEK293T cells that overexpress PMCA4 is inhibited on a concentration-dependent behavior, in a similar way that in purified PMCA. Altogether, results show that the quercetin- Mg^{2+} complex is the true inhibitor of PMCA both in purified enzyme and in cultured cells.

(1740) **REGULATION OF THE MOLECULAR FUNCTION**

OF α7 NICOTINIC RECEPTOR BY PHOSPHORYLATION

Juan Facundo Chrestia, María Del Carmen Esandi, Cecilia Beatriz Bouzat
Instituto de Investigaciones Bioquímicas de Bahía Blanca (INIBIBB) CONICET; Departamento de Biología, Bioquímica y Farmacia, Universidad Nacional del Sur.

α7 is one of the most abundant nicotinic receptors in the nervous system. It is highly expressed in the brain and contributes to cognition, attention, and working memory. The receptor contains an extracellular domain, which carries the agonist binding sites; a transmembrane domain, which forms the ion pore and the gate; and an intracellular domain (ICD), which contains sites for modulation and intracellular signaling. The concept of α7 as a dual metabotropic/ionotropic receptor is attracting increasing attention. Reciprocal crosstalk between phosphorylation-dependent signaling and receptor function has been proposed. However, the regulation of ion channel function by phosphorylation remains unclear. We here explored how tyrosine phosphorylation at ICD affects single-channel function of human α7 by combining site-directed mutagenesis and mammalian cell expression with patch-clamp recordings. We generated two mutant α7 receptors to prevent phosphorylation of key tyrosine residues (α7Y386F and α7Y442F). Wild-type α7 channel activity elicited by ACh consists of brief and isolated openings and less often as few brief openings in quick succession (bursts). We found that the mutations do not affect single-channel amplitude. However, visual inspection of the recordings showed sporadically long-duration bursts that were not detected in the wild-type receptor. To quantify these differences, we analyzed the burst duration histograms. Whereas wild-type α7 histograms are fitted by 2 components, about 40% of the recordings of α7Y386F and 20% of α7Y442F show a third component. This component corresponds to a novel population of long-duration bursts. Our results show that the decrease of phosphorylation increases open-channel duration, probably by reducing fast desensitization, which is the main pathway for terminating an opening event in α7.These findings reveal a novel regulatory mechanism that may be important in receptor function.

(1) Instituto de Química y Fisicoquímica Biológicas. Prof. Paladini. Departamento de Química Biológica, Facultad de Farmacia y Bioquímica. Universidad de Buenos Aires. (2) CIHIDECAR-CONICET. Departamento de Química Orgánica, Facultad de Ciencias Exacta y Naturales. Universidad de Buenos Aires.

Abstract: The Plasma Membrane Calcium ATPase (PMCA) is a P-type ATPase that maintains the homeostasis of Ca^{2+} in eukaryotic cells. It couples the transport of Ca^{2+} with the hydrolysis of ATP. The structure of PMCA is still not solved, and only limited information is available of ligand binding sites. The purpose of this work is to identify and characterize the calcium binding site of PMCA. We synthesized azido-ruthenium (AzRu), a photoactivatable reagent designed to obtain structural information, which binds covalently and specifically to Ca^{2+}-binding proteins after irradiation at 290 nm. The experiments were performed with purified PMCA from human erythrocytes. The results show that AzRu irreversibly inhibits PMCA activity. The time course of production of inorganic phosphate was measured before and after the addition of AzRu, in conditions where photolysis of the inhibitor was prevented. It was observed that the rate of inhibition by AzRu decreases by increasing $[Ca^{2+}]$ in the medium, whereas this rate remains unaffected by increasing $[Mg^{2+}]$. These results suggest that the calcium binding site would be involved in the inhibition process. Assays with $[\gamma\text{-}^{32}P]$ ATP indicate that inhibition of the ATPase activity was accompanied by an increase in the phosphorylated intermediate levels, which suggests that AzRu could be blocking the dephosphorylation of the pump. The photolabeling experiments with AzRu were observed by mass spectrometry using calmodulin (CaM) and lysozyme. CaM-AzRu adducts were observed but not with lysozyme. The results confirm the specific interaction of AzRu with calcium dependent proteins. Photolabeling mass spectra of PMCA with AzRu showed the disappearance of signals from certain peptides from the cytoplasmic domains suggesting an interaction with AzRu. Due to the difficulty of studying membrane proteins by mass spectrometry, we are evaluating an optimization of the study of the transmembrane domain where the PMCA-AzRu adduct would be found.

(692) **STUDY OF THE MECHANICAL GATING OF THE AQUAPORIN FAPIP2;1 FROM STRAWBERRY**

Cynthia Acuña, Micaela Pandolfo, Guillermo Jerez Ferreyra, Moira Sutka, Marcelo Ozu
Departamento de Biodiversidad y Biología Experimental, Facultad de Ciencias Exactas y Naturales, UBA.

Recently, we published the first works that experimentally demonstrate the direct regulation of both plant and animal aquaporins by membrane tension (s) changes. Our recent work with *Bv*TIP1;2 and *Bv*PIP2;1 from red beet show that the first one is mechanosentive while the second one is not. This different behavior could be related to the differential distribution of GxxxG sequences (suggested to be responsible for mechanosensitivity in ion channels) observed by homology modeling. Previously we demonstrated that hAQP1 is a mechanosensitive channel. Both the water permeability (P_f) and the elastic volumetric coefficient (E) are negatively correlated in experiments with hAQP1 and *Bv*TIP1;2 (R^2>0.98), indicating that these aquaporins close with s increments. Phylogenetics analysis indicate that AQP1 and PIPs share a common ancestor and that divergence of the AQP1-PIP and TIPs groups occurred earlier in evolution. Therefore, three hypotheses arise for mechanosensitivity: 1) it would had been present in the ancestor of AQP1-PIPs and TIPs and was lost in PIPs; 2) it appeared in AQP1-PIPs and TIPs by separately; 3) *Bv*PIP2;1 is a mechanosensitive channel but less sensitive than hAQP1 and *Bv*TIP1;2. Now, we are studying the mechanosensitive properties of *Fa*PIP2;1 from strawberry. The homology model of *Fa*PIP2;1 shows differences with *Bv*PIP2;1 and similarities with *Bv*TIP1;2, suggesting that *Fa*PIP2;1 could behave as a mechanosensitive aquaporin. By means of simultaneous V and P measurements in Xenopus oocytes expressing *Fa*PIP2;1 we determine P_f and E under osmotic gradients. Our previous results with osmotic gradients up to 200 $mOmol.Kg_{H2O}^{-1}$ (E=0.5-0.8 KPa) showed that *Bv*PIP2;1 is not regulated by membrane tension changes. Preliminary results with *Fa*PIP2;1 show that this aquaporin does not behave as a mechanosenstive channel, at least up to changes induced with 200 $mOmol.Kg_{H2O}^{-1}$.

(1757) **AMYLOID β PEPTIDE DECREASES α7 RECEPTOR POTENTIATION**

Matías Lasala, Camila Fabiani, Romina Uranga, Silvia Antollini, Jeremías Corradi, Cecilia Bouzat
Instituto de Investigaciones Bioquímicas de Bahía Blanca. CONICET Departamento de Biología, Bioquímica y Farmacia. Universidad Nacional del Sur

Amyloid β peptide (Aβ) is a key player in the development of Alzheimer disease (AD). Aβ is visible as the primary component of senile plaques in the brains of Alzheimer's patients. Cholinergic activity mediated by human α7 nicotinic receptors is decreased in AD, and potentiation of α7 by positive allosteric modulators (PAMs) is emerging as a novel therapeutic strategy for improving memory and cognition. There are reports showing functional interaction of Aβ with α7, but the reported effects are very varied and the underlying mechanisms are not clear. Here we explored the effect of Aβ1-40 and Aβ1-42 on human α7 at the patch-clamp single-channel level. α7 channel activity elicited by 100 μM ACh consists of brief and iso-

lated openings. In the presence of PAMs, open channel lifetime is increased and openings appear grouped in long activation episodes. The type II PAM PNU-120596 (1 μM) prolongs open durations and elicits activation episodes of ~2 s. In the presence of Aβ there is a statistically significant decrease in the mean duration of the potentiated activation episodes, which is 2.6-fold at 100 nM Aβ1-40 ($p<0.001$, n=11) and 2-fold at 100 nM Aβ1-42 ($p<0.05$, n=10). To determine if the effect is specific for PNU-120596, we also tested NS-1738, which is an α7 type I PAM. Again, a 2-fold reduction in the duration of the activation episodes is observed ($p<0.001$). Complementary fluorescence spectroscopic studies using a fluorescent channel blocker, crystal violet, that binds with different affinities to resting and desensitized receptors provide insights into the functional changes. Our results demonstrate that Aβ inhibits potentiation of human α7, probably through an allosteric mechanism which involves slow block or increased desensitization. Deciphering the functional interaction between α7 and Aβ contributes to the understanding of the involvement of α7 in the pathophysiology of Alzheimer disease.

Camila Fabiani, Jeremías Corradi, Silvia Antollini
Instituto de Investigaciones Bioquímicas de Bahía Blanca CONICET - Departamento de Biología, Bioquímica y Farmacia Universidad Nacional del Sur, Bahía Blanca, Argentina.

Cholinergic deficit is regarded as an important factor responsible for Alzheimer's disease symptoms. Two molecular targets for the treatment of this disease are acetylcholinesterase (AChE) and nicotinic receptor (nAChR). Caffeine (CAFF) acts as a non-competitive inhibitor of AChE but its mechanism of action on nAChR is still unknown. To this end, we first explored if CAFF influences the nAChR conformational state using the AChR conformational-sensitive probe crystal violet (CrV) and AChR-rich membranes from *T. californica*. CAFF induced changes in the KD value of CrV in a concentration-dependent manner taking the nAChR to a state close to the desensitized one. In the presence of α-bungarotoxin, a specific nAChR competitive antagonist, high concentrations of CAFF increased the KD value of CrV, compatible with a competition for the CrV site in the channel pore. The same effect was seen with galantamine, an AChE inhibitor and partial agonist of nAChR. To understand the molecular mechanism underlying the conformational changes of the nAChR, we expressed adult muscle or neuronal a7 nAChRs in BOSC cells, and performed single channel recordings with different CAFF concentrations in the presence or absence of ACh. At low concentrations (1-300 μM), CAFF activated muscle and a7 nAChRs, and the activation profile was independent of CAFF concentration. On the other hand, at high CAFF concentrations (up to 20 mM), the mean open duration decreased, the relative area of the briefer closed component and the cluster duration increased, and a flickering behavior was observed, these suggesting that CAFF acts as an open channel blocker. Thus, we here demonstrate a dual effect of CAFF on muscle and a7 nAChRs, behaving as a weak agonist at low concentrations and as a negative modulator at high concentrations. Our results bring new information about the mechanism of modulation of pharmacology targets for the design of new therapies for the intervention in neurological diseases.

Key words: Caffeine, nicotinic receptor, crystal violet, single channel recordings.

Abstract: In natural environments microbes live in multicellular structures called biofilms, in which cells are embedded in a matrix of self-produced biopolymers. The extracellular matrix determines the immediate conditions of life of biofilm cells, and also provides adhesion to surfaces and mechanical stability. Despite the importance of the matrix in the biofilm mode of life, very little is known about the mechanisms leading to matrix assembly and the extracellular proteins involved in this process. We have recently characterized the RapA lectin secreted by *Rhizobium leguminosarum*, which has a profound impact in the organization of the biofilm matrix. The RapA lectin interacts specifically with the acidic exopolysaccharides (EPS/CPS) produced by *R. leguminosarum* in a calcium-dependent manner. The protein is composed of two CHDL domains that are similar to the extracellular domains of eukaryotic cadherins. Aiming to obtain a tool to study the development of the matrix during biofilm formation, we dissect the protein in its two halves, and study the properties of the individual CHDL domains. The domains were amplified by PCR using specific primers, cloned as His tag fusions and purified from the soluble fraction of *Escherichia coli* BL21(DE3) induced cells. The purified domains were analyzed by CD spectroscopy with the addition of calcium ions, and in a functional test by means of a binding inhibition assay (BIA) with the EPS. Our results show that the lectin activity is confined to the carboxy terminal CHDL domain of RapA, which contains the calcium binding site and is able to bind to the EPS, although with less affinity than the entire RapA lectin.

Keywords: lectin, calcium, biofilm matrix, exopolysaccharide.

(279) **STRUCTURE OF DIFFERENT PHOSPHORYLATED STATES OF PLASMA MEMBRANE CALCIUM PUMP**

Nicolás Andrés Saffioti (1), Marilina De Sautu (1), Rolando Rossi (1), Joshua Berlin (2), Juan Pablo Rossi (1), Mariela Ferreira-Gomes (1), Irene Cecilia Mangialavori (1)
(1) Instituto de Química y Fisicoquímica Biológicas, Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, CONICET, Buenos Aires, Argentina. (2) Department of Pharmacology and Physiology, New Jersey. Medical School, Rutgers University, Newark, NJ, USA.

The control of the cytoplasmic calcium homeostasis relies on many transporters like the Plasma Membrane Calcium Pump (PMCA) and the Sarcoplasmic Reticulum Calcium Pump (SERCA) which belong to the P-ATPase family. At difference with SERCA, structure and function of PMCA has not been fully elucidated yet, because obtaining suitable preparations for X-ray crystal diffraction and NMR techniques was unsuccessful.

To elucidate the structural changes produced in PMCA during the reaction cycle we tested a purified preparation of the pump with fluoride complexes of beryllium, aluminum and magnesium, each one stabilizing different analogues of phosphorylated intermediates in P-ATPases. These blockers were previously assayed in SERCA leading to different conformational states. To follow the binding of fluoride complexes by fluorescence we employed eosin, which binds to the N domain of PMCA. Quantum yield of the bound probe decreased in the presence of fluoride complexes indicating more exposure to solvent. The magnitude of this change depended on the presence of calcium and the complex identity.

Following the kinetics of the conformational change, we propose a model to explain how these complexes stabilize phosphorylated states in PMCA. The detectable conformational change associated with an intermediate of the reaction cycle also allows us to develop a method to measure PMCA activity using a fluorescence approach. Finally, we prepared and refined PMCA structural models based on homology with SERCA and Na^+/K^+ ATPase at different states, to understand the changes at the nucleotide-binding domain during the catalytic cycle of PMCA.

(727) **HOW DEEP IS YOUR BLUE? A NOVEL COPPER CONTAINING NITRITE REDUCTASE FROM A THERMO-**

PHILIC BACTERIUM ISOLATED FROM THE SOUTH AFRICAN DEEP SURFACE

Felix Martin Ferroni (1), Florencia Belen Schmidt (1), Carlos Dante Brondino (1), Dirk Opperman (2)
(1) Departamento De Física, Facultad De Bioquímica Y Ciencias Biológicas, Universidad Nacional Del Litoral. Santa Fe, Argentina. (2) Department Of Biotechnology, University Of The Free State. Bloemfontein, South Africa.

Abstract: many microorganisms of the genus *Thermus* have been isolated from hot environments around the world but particularly *Thermus scotoductus* SA-01 was isolated from fissure water collected 3.2 km below the surface in a South African gold mine. Denitrification is a relevant energy pathway in this kind of microorganisms and the presence of both a cytochrome cd_1 (NirS) and a copper containing nitrite reductase (NirK) is exceptional. The genome of *T. scotoductus* SA-01 showed the presence of genes for both enzymes. Here we present the expression, purification and the structural and functional characterization of NirK from *T. scotoductus* SA-01 (*Ts*NirK). *Escherichia coli* BL21(DE3) Gold cells were used to express the optimized Tsc_c17620 gene inserted into pET22b(+). The recombinant *Ts*NirK was purified by several chromatographic steps and the turquoise pure enzyme showed different spectroscopic features from those observed in green/blue NirKs. Gel filtration analysis showed an elution peak corresponding to a homotrimer and metal analysis reported 3 mol copper per mol monomer. We proceeded on protein crystallization screening assays and *Ts*NirK crystals developed in several conditions. Single crystals grown in 0.2 M $CaCl_2$.2 H_2O 0.1 M HEPES sodium pH: 7.5 28% w/v PEG 400 and diffracted at 1.63 **Å** (beamline I04-I, Diamond Synchrotron, UK). The obtained overall structure reveals a homotrimer with 3 copper atoms per each subunit. The catalytic type 2 copper center (T2Cu) is 12.6 **Å** His-Cys bridged to a non-common type 1 copper center ($T1Cu_{N\text{-}ter}$). An extra cupredoxin domain is located at the C termini of each monomer and binds a normal type 1 copper center ($T1Cu_{C\text{-}ter}$) that resembles amicyanin. Thermal stability, kinetic properties and structural features make this enzyme a good candidate for the development of nitrite biosensors.

(851) **BIOPHISICAL AND BIOCHEMICAL CHARACTERIZATION OF PLASMID-MEDIATED COLISTIN RESISTANCE DETERMINAT MCR-1**

Pablo Emiliano Tomatis (1), Alejandro Jose Vila (1)
(1) IBR (CONICET-UNR).

Polimyxin antibiotics, as colistin, are commonly referred as a last-chance to treat multidrug-resistant gram-negative infections. This positively charged peptide can binds to the negatively charged lipid A core, disrupting the bacterial outer membrane. Unfortunately, in 2016 a transferable colistin resistance mechanism was reported, a plasmid-encoded phosphoethanolamine transferase MCR that has rapidly disseminated worldwide. MCR catalyzes the transfer of positively charged phosphoethanolamine onto lipid A, decreasing the net negative charge and preventing colistin binding and antibiotic success. It is a metalloenzyme embedded in the inner membrane, with the catalytic center in a periplasmic soluble domain. Recently, four structures of the soluble catalytic domain have been reported, depicting a zinc metalloprotein. Despite structural equivalence, the stoichiometry on metal content is controversial. This information is pivotal for further mechanistic analysis to gain information for inhibitor design.

Based in previous studies, we have cloned the catalytic periplasmic domain in different expression vectors. According to soluble protein yields, BL21 (DE3) *E. coli* cells expressing the catalytic domain with a His 6x tag and a TEV protease recognition site were selected for further protein production. Bacterial culture condition were tested with different Zn(II) ion concentrations, in order to evaluate the metal content in the purified protein using PAR as a Zn indicator. In all tested conditions, the catalytic domain was able to take up to one Zn(II) ion equivalent.

Metal quelator EDTA was used to obtain apo-proteins derivatives, to further characterize the metal active site using Co(II) as spectroscopic probe. CoCo and ZnCo adduct were produced and the ligand field bands showed a tetrahedral geometry pattern. Secondary and tertiary structural features and relative stability of the apo and metal adducts were also tested by circular dichroism spectroscopy.

Emilio Saita (1), Luciano Abriata (2), Diego de Mendoza (1), Daniela Albanesi (1)
(1) Instituto de Biología Molecular y Celular de Rosario, (2) Swiss Institute of Bioinformatics), Matteo Dal Peraro (Swiss Institute of Bioinformatics

Propagation of a signal through transmembrane segments of a sensor protein is key at the initial stage of many complex signaling processes. The thermosensor histidine kinase DesK from *Bacillus subtilis* senses changes in membrane fluidity initiating an adaptive response. Structural changes in DesK have been implicated in transmembrane signaling, but direct evidence is still lacking. Based on structure-guided mutagenesis, we have proposed a mechanism of DesK-mediated signal sensing and transduction. Specifically, stabilization/destabilization of a 2-helix coiled coil, which connects the transmembrane sensory domain of DesK to its cytosolic catalytic region, is crucial to control its signaling state. Computational modeling and simulations reveal couplings between protein, water and membrane mechanics favoring such conformational changes. We propose that membrane thickening is the main driving force for signal sensing, and that it acts by inducing helix stretching and rotation prompting an asymmetric kinase-competent state. At present, we are dedicating our efforts to crystallize full-length DesK for X-ray structure determination, expecting to shed light on DesK's transmembrane sensing mechanics.

(1327) **ARCHITECTURE OF MECR1: A MEMBRANE-EMBEDDED METALLOPROTEASE DOMAIN POISED TO RECEIVE INFORMATION FROM THE EXTRACELLULAR SENSOR DOMAIN**

Bruno Salvador Belluzo (1), Luciano Abriata (2), Estefania Giannini (1), Matteo Dal Peraro (2), Leticia Irene Llarrull (1)

Abstract: **The signal transducer protein MecR1 from methicillin resistant *Staphylococcus aureus* regulates the expression of PBP2a, a protein that is not inhibited by clinical concentrations of most β-lactam antibiotics**. In this study we aimed at identify a structural model that present a better comprehension of the signal transduction mediated by MecR1, which is an attractive target for drug development.

By integrating homology modeling, residue co-evolution analysis, dynamic simulations and docking, we generated a model for the full length MecR1 protein. This model was used to design a series of constructions to further evaluate the topology in-vitro. Fluorescence spectroscopy and Proteinase K susceptibility assays in MecR1. eGFP truncated fusions and TEV peptidase susceptibility assays in MecR1.E205A.TEV insertions were carried out. As a whole, these data allowed us to corroborate the orientation of most transmembrane helixes, it showed that the peptide S63-T102 is extracellular (and not a TM helix) and that Loop 4 in the metalloprotease domain N194 to D213 has low flexibility, which could be due to compaction or membrane interaction. To further evaluate if the effector domain has membrane localization, the cytoplasmic domain (cytMecR1), was expressed in *E. coli*, and we found it was membrane embedded. These results support the existence of a reentering alpha-helix in the metalloprotease domain that tightly anchors this domain to the membrane, in accordance with our computational model.

In conclusion, we presented a model for full length MecR1 in which the metalloprotease domain is embedded in the membrane, defining a hydrophilic chamber. A reentering loop connecting the metal ligands tightly anchors the metalloprotease domain to the membrane (even in the absence of the rest of the TM helixes) and reaches to the outer leaflet of the membrane where it is posed to interact with

the sensor domain loops that show altered mobility upon antibiotic binding.

Staphylococcus aureus is the leading cause of both nosocomial and community-acquired infections. In *S. aureus* the *vraSRT* three-component system acts as a sentinel that can rapidly sense cell wall peptidoglycan damage and coordinate a response that leads to resistance to β-lactam and glycopeptide antibiotics. VraS and VraR encode a histidin-kinase and a response regulator, respectively. However, the rol of VraT is yet unknown. We still do not understand how VraS is activated in response to cell wall-active antibiotics.

The interaction between VraS (the possible sensor), VraT and different photoprobes derived from ampicillin was studied. The photoaffinity probes were used for covalent labelling of VraS and VraT in *E. coli* spheroplasts, and the interaction was evidenced by an electrophoretic mobility shift in the case of VraS, although no interaction was seen with VraT. We used a *S. aureus* reporter strain to confirm that the ampicillin-derived photoprobes effectively activate the *vraSRT* system. The VraS-photoprobe complexes were purified and analyzed by MALDI-TOF/TOF. In this study we also addressed the topology of VraT in membranes. Using a Proteinase K susceptibility assay we determined that the C-terminal domain of VraT has extra-cytoplasmatic location.

Keywords: Staphylococcus aureus; *vraSRT*; photoaffinity ampicillin-derived probes.

(1381) **FUNCTIONAL EXPRESSION OF HUMAN PARK9-ATP13A2 P5-ATPase IN *Saccharomyces cerevisiae*.**

Alejandra Lucía Marcos, Gerardo Corradi, Hugo Adamo, Felicitas De Tezanos Pinto
IQUIFIB FFyB (UBA-CONICET)

The P-type ion pumps are membrane transporters energized by ATP-hydrolysis. They were classified into five subfamilies termed P1-P5; the substrate specificity of P5 subfamily is still unknown. Five genes named *ATP13A1-ATP13A5* that belong to the P5-ATPases are present in humans, while two named Spf1p and Ypk9p were found in the yeast *S. cerevisiae*. By DNA sequence alignment it was shown that P5-ATPases were classified in groups P5A and P5B; the mouse gene Atp13a1 and the yeast gene coding Spfp1 (Yel031w) are members of the first group, while the mouse genes Atp13a2-Atp13a5 and the yeast gene coding Ypk9p (Yor291w) are clustered into the second one. Mutations of the ATP13A2 gene, also known as PARK9, are associated with a form of Parkinson's Disease (Kufor-Rakeb syndrome), a form of Neuronal Ceroid Lipofuscinosis (CNL12) and hereditary spastic paraplegia (SPG78). ATP13A2 is localized in lysosomes and late endosomes (LEs). Dysfunction of this protein diminishes the lysosomal degradation, the autophagic flux and the exosome externalization. In order to advance the biochemical characterization of ATP13A2, *S.c* cells were transformed with the pMP625 vector coding for GFP tagged-ATP13A2 protein and the clone exhibiting the highest GFP-fluorescence intensity selected. Yeasts expressing GFP-ATP13A2 showed a reduced growing rate and an autophagic phenotype characterized by vacuolar multivesicularization. The recombinant fusion protein was purified from microsomal membranes by pseudo-affinity chromatography. Analysis of the eluate by SDS-PAGE and western blot indicated that ATP13A2 was successfully expressed and had the expected molecular size. Preliminary experiments measuring the release of free phosphate from ATP by the Baginsky's assay showed that the purified GFP-ATP13A2 is a functional ATPase.

(154) **STRUCTURE-FUNCTION RELATIONSHIP OF A NOVEL LECTIN FROM *Pomacea diffusa* SNAIL EGGS**

Tabata Brola (1), Marcos Dreon (1, 2), Horacio Heras (1, 3)
(1) Instituto de Investigaciones Bioquímicas de La Plata (INIBIOLP), Universidad Nacional de La Plata (UNLP) -CONICET CCT-La Plata. (2) Cátedra de Bioquímica y Biología Molecular, Facultad de Ciencias Médicas, UNLP. (3) Cátedra de Química Biológica, Facultad de Ciencias Naturales y Museo, UNLP.

Pomacea freshwater snails lay eggs above water exposing them to environmental stressful conditions and predation. Despite this, *P. canaliculata* and *P. maculata* have been able to establish themselves out of their native range and became important invasive species. The perivitelline fluid (PVF) of their eggs contains antinutritive carotenoproteins and a neurotoxin, which participate in the embryo defence system against predation. By contrast, the PVF of the non-invasive species *P. scalaris* lacks of neurotoxin and its carotenoprotein (PsSc) besides its antinutritive role, displays a potent lectin activity also involved in the egg defence system.

In this work, we studied the PVF of *P. diffusa* a closely related species to *P. scalaris* searching for neurotoxins and isolated and characterized a carotenoprotein named PdPV1. Molecular weight and global shape of PdPV1 were estimated by PAGE, SEC and SAXS. N-terminal and mass spectrometry followed by full cDNA sequencing and bioinformatic analysis were performed on each subunit. PdPV1 resistance to gastrointestinal digestion was evaluated *in vitro* and its lectin activity characterized by hemagglutination assays.

PdPV1 is an anisometric oligomer of 422 KDa resistant to *in vitro* gastrointestinal digestion. It is composed by 6 subunits of ca. 26 KDa showing >90% sequence similarity with PsSc. Though PdPV1 was able to agglutinate different erythrocytes no sequence similarity to any known lectin could be found. Its activity was inhibited by galactose, galactosamine and N-Acetylgalactosamine. No neurotoxins were found in the PVF.

The combination of a carotenoprotein with lectin activity and the absence of neurotoxins as was previously described for *P. scalaris,* suggest an alternative defence system against predation involving lectins. These remarkable defensive differences among *Pomacea* species may explain the invasiveness and the wider geographical distribution of *P. canaliculata* and *P. maculata* compared to *P. scalaris* and *P. diffusa*.

(1391) **STRUCTURALLY EXPOSED SITES AND INTERACTORS OF BCY1, THE REGULATORY SUBUNIT OF PROTEIN KINASE A FROM *Saccharomyces cerevisiae*, ANALYZED BY MASS SPECTROMETRY.**

Enzo Tofolon, Pía Valacco, Ricardo Neme Tauil, Germán Fernández, Silvia Rossi, Silvia Moreno
Dpto. de Qca. Biológica, FCEyN,UBA-IQUIBICEN-CONICET.

Protein kinase A is an inactive tetramer formed by a dimer of regulatory subunit (R2) bound to two monomers of catalytic subunit (C). When two molecules of cAMP bind to each R, the affinity between R and C is decreased and active C subunit is released. In mammals, the N-terminus of R subunits (DD) is responsible for the homo-dimerization and for anchoring the AKAPs and thus localizes the signal transduction pathway. In yeast, PKA is also a tetramer; the N-terminus of Bcy1 (R subunit) is responsible for dimerization and for its own localization. No AKAPs have been described yet except for our own preliminary report.

Our study was carried out by proteomic approaches. On one hand, the goal was to obtain information on exposed sites in Bcy1 to reconstruct/model the whole structure, studying three proteolytic bands derived from aged Bcy1 by MALDI TOF-TOF and nano-LC-ESI-Or-

bitrap (QExactive). On the other hand, to investigate the oligomeric of structure Bcy1 *in vivo* and search for *in vivo* interactors by overexpression in yeast of its dimerization/docking domain, 1-50 Bcy1 (DD), tagged with thioredoxin-His in its N-terminus and analysis of the pulled down proteins after Ni-agarose.

The first approach indicates that Bcy1 has clear points of endogenous proteolysis that speak about its folding.

The results of the other approach suggest tetramer formation *in vivo* because of the intact endogenous Bcy1 presence in the pulled down using overexpressed His-Tagged DD domain. Together with Bcy1 a good number of proteins were also pulled down. Some of these proteins were selected for future studies as putative Bcy1 interactors according to rigurous criteria.

In conclusion, we have obtained information regarding the apparently exposed/labile sites of Bcy1 and the potential Bcy1 interactors, and demonstrate the tetramer formation *in vivo*.

(336) ABERRANT O-GLYCOSYLATION MODULATES AGGRESSIVENESS IN NEUROBLASTOMA

Héctor Adrián Cuello (1), Valeria I. Segatori (1), Marina Alberto (1), Cynthia A. Gulino (1), Rosario Aschero (2), Laura Galluzzo Mutti (2), Fabiana Lubieniecki (2.), Mariano R. Gabri (1)

(1) Molecular Oncology Laboratory, Quilmes National University, Bernal, Buenos Aires, Argentina. (2) Department of Pathology, Pediatric Hospital "Prof. Dr. Juan P. Garrahan", Buenos Aires, Argentina.

The role of glycans in the interaction between cells and microenvironment in adult cancer is widely reported, but little is known about their role in pediatric cancer such as Neuroblastoma (NB). Hence, the study of aberrant glycosylation is a promising field to understand NB transformation. In this work, we characterized the expression of glycans by flow cytometry, particularly truncated and Lewis family in Core 2 O-glycans, and the expression of enzymes involved in their biosynthesis (glycoenzymes) by qRT-PCR in five human NB cell lines and patients' derived primary tumor samples with different MYCN status. We also studied the role of Core 2-O-glycans in cell behaviour by C2GNT1 silencing, a key enzyme in their synthesis, as well as the binding to selectins. Results showed minimal expression of truncated glycans in all cell lines tested and higher expression of Lewis family antigens, associated with the MYCN-amplification status. High expression of C2GNT1 demonstrated Core 2 O-glycans association to MYCN-amplified cells as well ($p<0.001$). The main glycoenzymes responsible for Lewis antigens expression were sialyltransferase ST3Gal4 and fucosyltransferases (FUT) FUT4, 7 and 9. Similar results were obtained in patients' samples, showing overexpression of ST3Gals and FUTs in MYCN-amplified tumors in contrast with MYCN-non amplified ones, which suggest an overlapping role in these functions. Furthermore, MYCN-amplified cells showed higher E- and P- Selectin binding. Silencing of C2GNT1 provoked a decrease in cell attachment, proliferation and migration capacity *in vitro* ($p<0.05$). We also found a downmodulation in the expression of Lewis family glycans and accordingly, a significant decrease in E- and P-selectin binding ($p<0.05$). In this work, we demonstrated the impact of O-glycans in malignant NB cell behaviour, in particular of Lewis family glycans associated with Core-2 branching, the enzymes involved in their biosynthesis and their relation to MYCN amplification.

Breast cancer is the most common malignancy in women. The anti-estrogen Tamoxifen (TMX) is often used to treat patients with estrogen receptor positive (ER+) tumors. However, 40% of these tumors acquire resistance to TMX. This drug promotes breast tumor initiating cell (TIC) formation, which could lead to relapse. Aminoflavone (AF), a ligand of the aryl hydrocarbon receptor, exhibits antitumor efficacy in patients with ER+ breast cancer and reduces TIC number in breast cancer. The purpose of our current study is to determine whether AF combined with TMX (co-treatment) increases anticancer efficacy and reduces the tendency for TMX to increase TICs. We studied the cytotoxic effect of TMX, AF and both drugs combined in the LM05-mix (ER+) cell line using the MTS assay. AF induced 6-fold greater cytotoxicity than TMX ($p<0.05$) and co-treatment resulted in greater cytotoxicity than either drug used singly (60-fold higher than TMX and 9-fold higher than AF) ($p<0.05$). Treatment with AF alone or in combination with TMX caused a significant decrease in mammosphere numbers as compared to control (vehicle exposed): 18 fold and 50 fold respectively ($p<0.05$). The number of mammospheres formed after treatment with TMX was 15-fold higher than mammospheres after treatment with AF and 42-fold higher than mammospheres after co-treatment ($p<0.05$). Treatment with AF or co-treatment generated mammospheres of a smaller diameter than those obtained in the control: AF (1.5 fold decrease and 1.6 fold decrease respectively) ($p<0.05$). Finally, we investigated the miRNA profile in control and treated MCF-7 cells using miRNA-sequencing. AF caused a nearly 2-fold increase in miRNA-205 as confirmed by qPCR ($p<0.0001$). miRNA-205 exhibits tumor suppressor actions and tends to be down-regulated in TMX-resistant cells and in tumors of patients who relapse after TMX treatment. In vivo studies are underway to determine whether AF decreases the pro-tumoral effect of TMX.

(1150) DRUG REPOSITIONING FOR CANCER TREATMENT: METRONOMIC CHEMOTHERAPY WITH CYCLOPHOSPHAMIDE (CY) AND LOSARTAN (LOS) FOR THE M-234p MURINE MAMMARY ADENOCARCINOMA

Metronomic chemotherapy (MCT) refers to the chronic, equally spaced, delivery of low doses of chemotherapeutic drugs, without extended interruptions. Drug repositioning in oncology refers to the use of drugs formulated for other indications that showed antitumor potential. Cy is an alquilating agent with toxic action on proliferating cells. LOS is an antagonist of angiotensin II receptor, used to treat hypertension. Our aim was to study the combined effect of Cy+Los administered metronomically. Female BALB/c mice were challenged s.c. with M-234p (day 0) and distributed, on day 8, into 4 groups (n=6/group) treated as follows, GI: Control, no further treatment; GII: Cy 25mg/kg/day in the drinking water; GIII: LOS 200mg/kg/day in the drinking water; GIV: Treated as GII + GIII. Mice were weighted and tumor volume measured 3 times/week. When tumors were exponentially growing, mice were euthanized, tumors excised and used for immunohistochemistry (IHC). A significant inhibition of tumor growth was evident in group IV compared to GI, GII and GIII ($P<0.001$). Tumor doubling and survival times were also significantly higher in GIV ($P<0.001$). No weight losses were observed. IHC analysis showed higher N° of $CD4^+$ and CD^+8 lymphocytes and lower N° of $Ki67^+$ cells in GII and GIV, without reaching statistical significance. To evaluate the anti-metastatic effect of the therapy, mice were inoculated i.v. with $5x10^5$ M-234p cells. On day 3, mice were distributed in the same experimental groups. When the first mouse showed signs of metastatic disease, all of them were euthanized, lungs excised and stained to highlight metastasis. The N° of lung metastasis was lower in GII and GIV. In conclusion: MCT with Cy+LOS inhibited

M-234p growth and increased mice survival without general toxic effects; the combined treatment was more effective than the individual drugs; Cy and Cy+LOS diminished lung metastases; these results show the convenience of using Losartan in antitumor treatments.

(112) **EFFECT OF RETINOIC ACID (ATRA) TREATMENT ON GROWTH AND MALIGNANT PROGRESSION OF HUMAN MAMMARY TUMOR CELLS OVEREXPRESSING PROTEIN KINASE C ALPHA (PKCα)**

María Inés Diaz Bessone, Damián Emilio Berardi, Stéfano Martín Cirigliano, María Agustina Taruselli, Agostina Cammarata, Laura Beatriz Todaro, Alejandro Jorge Urtreger
Instituto de Oncología "A. H. Roffo"

Abstract: PKC enzymes constitute a family of serine-threonine kinases that control numerous cellular functions, such as growth, apoptosis and malignant transformation, whereas the retinoid system is involved in cell differentiation.

In this work, we studied the effect of retinoid treatment on characteristics associated with tumor progression of MDA-MB231 and T47D cell lines overexpressing PKCα.

PKCα overexpression was unable to alter the proliferative capacity of both cell lines *in vitro*. When we assess the effect of ATRA, T47D-PKCα cells significantly decrease their proliferative capacity, whereas MDA-MB231-PKCα did not respond to retinoid treatment. Cell cycle analysis, by flow cytometry, showed that ATRA induces an arrest in the G1 phase, only in the T47D subline.

Next, we analyzed the functionality of Retinoic Acid Response Elements (RARE) by a gene reporter assay. Both T47D and MDA-MB231 derived sublines responded to ATRA increasing RARE activity. Then, we studied AP1 sites since retinoids effects also involve the trans-repression of this element. Although T47D sublines showed a decrease in AP1 activity when treated with ATRA, no effect was observed in MDA-MB231.

Retinoid receptors expression (analyzed by RT-qPCR) showed that MDA-MB231 cells were unable to increase RARβ and RARγ levels in response to retinoid treatment, as it was observed in T47D cells. As the repression of AP1 sites, induced by ATRA, has been assigned to RARβ we overexpress this receptor in MDA-MB231 cells. Now a clear trans-repression of AP1 sites was observed after ATRA treatment.

Our results suggest that PKCα sensitize T47D cell to retinoid treatment, which correlates our previous observations in murine lines. On the other hand, the lack of response to retinoid treatment of MDA-MB231 could be due to the inability to trans-repress AP1 sites, due the lack of RARβ expression.

Keywords: PKCα, ATRA, RARE sites, AP1 sites.

(786) **THE ANTITUMOR EFFECT OF CIGB-300 PEPTIDE, A PROTEIN KINASE CK2 INHIBITOR, IN MAMMARY CANCER MODELS**

María Florencia Gottardo (1), Carla Sabrina Capobianco (1), Johanna Elena Sidabra (1), Yasser Perera (2), Silvio Perea (2), Daniel Fernando Alonso (1), Hernan Gabriel Farina (1)
(1) Laboratory of Molecular Oncology, Quilmes National University, (2) Laboratory of Molecular Oncology, Division of Pharmaceuticals, Center for Genetic Engineering and Biotechnology (CIGB).

CK2 is a serine-threonine kinase that has been involved in growth, proliferation and cell apoptosis. CK2 has a constitutive expression and it has more than 300 substrates. In recent years, CK2 became an interesting target for anticancer therapies. Inhibition of CK2 showed antitumor activity in different types of cancer. CIGB-300 is a peptidic inhibitor of CK2, designed to bind to the phospho-acceptor domain of CK2 substrates, impairing the correct phosphorylation by the enzyme. Because breast cancer is one of the main tumor types in which CK2 is overexpressed, we focus on the effect of CK2 inhibition as a modulator of key features of breast cancer cell biology.

Previously, we showed that CIGB-300 reduced the proliferation, spreading capability and ERK phosphorylation of tumor cells in a murine breast cancer model. The aim of the present study was to evaluate the role of inhibition of CK2 by CIGB-300 in murine and human mammary carcinoma cell lines. For this purpose, we evaluated the action of CIGB-300 on viability, apoptosis and clonogenic capacity using three different breast tumor cell lines, MCF7 (positive for estrogen, progesterone and HER2-neu receptors), MDA MB 231 (representative of triple negative tumors) and F3II, a murine mammary carcinoma. As compared the potential of CK2 inhibition in these models we included another chemical inhibitor of the enzyme, CX-4945.

Our results showed that CIGB-300 reduced the viability of MDA MB 231 (IC50=120 μM) and MCF-7 (IC50=140 μM) ($p<0.05$, ANOVA). We observed that in both human and murine cell lines CIGB-300 exerts a pro-apoptotic action (TUNEL assay, $p<0.05$, $\chi 2$). We also found that the inhibition of CK2 by CIGB-300 decreased the clonogenic capacity of F3II, MCF-7 and MDA-MB-231 ($p<0.05$, ANOVA).

These preliminary results support the relevance of CK2 enzyme as molecular target in breast tumor cells.

(971) **EFFECTS OF METFORMIN AND GLUCOSE RESTRICTION ON THE INVASIVE CAPACITY OF HCC CELLS: MODULATING AMPK ACTIVATION**

Anabela Cecilia Ferretti, Florencia Hidalgo, Facundo Mauro Tonucci, Evangelina Almada, Alejandro Pedro Pariani, María Cecilia Larocca, Cristián Favre
IFISE-CONICET

AMPK is an antioncogenic kinase whose dysfunction has been related to hepatocellular carcinoma (HCC) etiology. We have demonstrated that AMPK induces cell-cycle arrest and death in HCC cells undergoing glucose restriction, and that AMPK is inhibited by PKA phosphorylation (S173), which prevents apoptotic death. AMPK decreases migration/invasion in different cell lines, but its effects in HCC cells remain unclear. We have previously shown that metformin and other AMPK activators decrease HCC cells migration. Metformin possesses promising antitumor effects via AMPK and inhibits PKA, as well.

We aim to study AMPK role on migration/invasion of HCC cells treated with metformin and its modulation by PKA.

Invasion assays showed that 1 (M1) and 5 (M5) mM metformin decreased invasion of C3A (M1:52.3±11.8*, M5:16.5±9.3* %) and HuH-7 (M1:67.5±4.9*, M5:24.8±12.1* % vs C) cells. AMPK knockdown prevented this effect. Besides, metformin induced apoptotic death.

When C3A cells were subjected to glucose starvation (GS), decrease of invasion (M1GS:24.8±14.1* % vs M1) and apoptosis percentage (M5GS:71.5±3.4* vs M5:52.4±6.8 %) were enhanced.

P-AMPKα(T172) and PKA phosphorylated substrates in cell lysates were analyzed. Metformin increased AMPK activation in a dose dependent manner, and decreased PKA activity at 5 mM. AMPK activation was significantly potentiated when cells were incubated with M5 combined with GS, whilst PKA activity was almost undetectable.

We performed invasion assays in C3A cells stable expressing WT and S173C forms of AMPK. S173C cells had lower invasion levels in response to AMPK activation (S173C: GS:36.5±3.9*, M1:16.5±1.3*, AICAR:4.0±0.4* % vs WT: GS:62.6±3.7, M1:51.9±7.4, AICAR:23.2±2.8 %).

We demonstrated that effects of metformin are enhanced by glucose restriction, and this is related, at least in part, to a greater activation of AMPK associated to PKA inhibition. We conclude that AMPK(S173) phosphorylation by PKA prevents AMPK anti-invasive effects. *$p<0.05$.

(464) **FLUOXETINE AND SERTRALINE TREATMENT PREVENTS STRESS-INDUCED ALTERATIONS IN TUMOR CELL CYCLE PROTEINS RELATED TO ENHANCED TUMOR PROGRESSION IN EL4 LYMPHOMA. PARTICIPATION OF THE IMMUNE SYSTEM.**

María Emilia Di Rosso (1), Helena Sterle (1), Graciela Cremaschi (1), Ana María Genaro (1, 2)
(1) Instituto de Investigaciones Biomédicas (BIOMED - CONICET - UCA). (2) Departamento de Farmacología, Facultad de Medicina, Universidad de Buenos Aires (UBA).

Selective serotonin reuptake inhibitors, as fluoxetine (F) and sertraline (S), are frequently used for the treatment of stress-associated disorders. However, there is contradictory evidence about their effect on the immune system and cancer prognosis. We have previously reported that both F and S are able to revert chronic stress enhancement of EL-4 lymphoma growth. In the present work we studied the effect of F or S on chronic stress-induced alterations in tumor cell cycle progression and in the anti-tumor immunity. Female C57BL/6J mice were treated with of F or S and subjected (E) or not (C) to a heterotrophic chronic stress for five weeks. Then, mice were subcutaneously injected with EL4 T lymphoma cells to generate a solid tumor. Tumor mRNA expression of proteins related to regulation and promotion of cell cycle was assessed by qRT-PCR. mRNA levels of cyclins A2, D1 and D3 were increased in tumor from E mice compared to C ($P<0.01$). In addition, cell cycle inhibitors p15, p16, p21 and p27 mRNA levels were decreased in tumors from E animals compared to C ($P<0.01$). Both F and S treatment resulted in C values of mRNA expression of these regulatory proteins. To determine the involvement of alterations in anti-tumor immune response in the stress-induced tumor growth, adoptive transfer experiments were performed. For this purpose, irradiated animals were tail vein injected with lymphoid cells of C and E animals treated or not with F and S and then inoculated with tumor cells. Data indicated that tumor growth was increased in mice injected with lymphocytes from E mice as compared to those transferred with immune cells from C animals. Furthermore, mice injected with immune cells from E animals treated with F and S did not show this effect. These results suggest that antidepressant treatment prevents stress induced tumor growth by avoiding chronic stress effects on the antitumor immunity.

CHRONIC STRESS – ANTIDEPRESSANTS – LYMPHOMA – ANTI-TUMOR IMMUNITY – TUMOR PROGRESSION

(984) **META-TYROSINE INHIBITS THE PROLIFERATION OF ESTABLISHED METASTASES IN A HUMAN MAMMARY ADENOCARCINOMA AND INDUCES APOPTOSIS IN TUMOR CELLS WITHOUT APPARENT TOXIC EFFECTS FOR THE ORGANISM**

Ariel Strazza (1), Daniela Montagna (1), Julieta Alcain (1), Gonzalo Sequeira (2), Mónica Vermeulen (1), Raúl Ruggiero (1), Paula Chiarella (1)
(1) IMEX-CONICET-ANM, (2) IBYME-CONICET.

The development of new strategies to limit metastatic growth after tumor removal is one of the greatest clinical challenges today. In previous work we have shown that meta-tyrosine (m-tyr), an isomer of tyrosine absent in normal proteins, is responsible, at least in part, for the phenomenon of Concomitant Tumor Resistance (CR); in which a tumor-bearing host inhibits the growth of secondary tumor implants. In this work we propose a deeper understanding of the molecular and antitumor mechanisms involved in CR as well as the study of the effectivity of its administration by the intraperitoneal (i.p) route. NOD *scid* gamma mice with a 41-day MDA-MB-231 human tumor received a daily i.p injection of 2.5 mg/mouse of m-tyr or saline (control) for 18 days. After the treatment all mice were sacrificed and lung metastases counted. At day 59 the number of metastases (Median [range]) was 10.0 [4-39] and 4.0 [0-14] for the control and m-tyr group respectively ($p<0.02$). We also analyzed signs of toxicity in BALB/c mice by the daily i.p administration of 2.5 mg/mouse of m-tyr for 39 days. Herein a hematological study was performed and the spleen was analyzed by flow cytometry. An increase in CD8+ T ($p<0.01$) and B220+ B cells ($p<0.02$) was observed in m-tyr group. Hematological analysis did not revealed significant differences in the number of granulocytes, monocytes and red blood cells. The number of total splenocytes was also higher in the m-tyr group ($p<0.03$). In addition, we observed apoptosis of murine LMM3 tumor cells cultured during 24 h in the presence of m-tyr ($p<0.05$). These findings suggest that the i.p route is effective in reducing the number of metastases and has no apparent toxic effects at the level of the organs studied. The increase in CD8+T lymphocytes caused by the daily administration of m-tyr could be associated with antitumor cytotoxicity and activation processes. The mechanism of activation of apoptosis caused by m-tyr in tumor cells still remains unknown.

Keywords: m-tyr, metastases, toxicity, human tumor, murine tumor.

(114) **NEW DRUGS FOR CANCER TREATMENT. EFFECT OF NORCANTHARIDIN AND LEVOGLUCOSENONE ON MALIGNANT PROGRESSION OF HUMAN AND MURINE MAMMARY TUMOR CELLS**

Lizeth Ariza Bareño (1), Agostina Cammarata (1), María Julieta Costa (1), Germán Giri (2), Rolando Spanevello (2), Alejandra Suarez (2), Laura Beatriz Todaro (1), Alejandro Jorge Urtreger (1)
(1) Instituto de Oncología "A. H. Roffo". (2) Instituto de Química de Rosario, Facultad de Ciencias Bioquímicas y Farmacéuticas, Universidad Nacional de Rosario-CONICET.

Abstract: In the present work, we start the evaluation of norcantharidin (NCTD) and levoglucosenone (Levo) on *in vitro* processes associated to malignant progression, using human and murine mammary tumor-derived cell lines.

Levo results from pyrolytic treatment of microcrystalline cellulose or cellulose-containing materials, and it has been used as the basis for the synthesis of a wide variety of compounds with different biological activities. Although it was shown that it could alter the cell cycle, its usefulness in oncology remains unexplored till nowadays. NCTD is a less toxic and demethylated form of cantharidin, an active constituent of Mylabris beetle, used in traditional Chinese medicine.

The effect of NCTD was analyzed on the triple negative mammary cell lines 4T1 and Hs578T, while the effect of Levo was analyzed on LM3 and MDA-MB231 cell lines. Both drugs proved to have a strong antiproliferative effect. NCTD exhibited an IC_{50} of 35 and 55 uM for 4T1 and HS578T cells respectively. In the case of Levo, the IC_{50} was 10 µM for the two cell lines analyzed. By flow cytometry we have determined that both drugs induced an increase in the sub-G1 fraction of the cell cycle, compatible with the presence of apoptotic cells. Related to *in vitro* malignant progression, we studied adhesion, migration (by wound healing assays) and secreted matrix metalloproteinases activity (by zymography) in all cell lines mentioned above, treated or not with both drugs. A significant reduction in all parameters associated to tumor progression was observed in a dose-dependent manner.

The important response to the treatments observed *in vitro*, suggests that these drugs could be useful for *in vivo* assays, hoping that in the future they could be suitable for breast cancer treatment.

(78) **NITRIC OXIDE INHIBITION REDUCE MIGRATION AND INVASIVENESS IN BLADDER TUMORS THAT EXPRESS iNOS BY DOWN-REGULATING VIMENTINA, CARMIL AND INCREASING RSU1**

Yanina Veronica Langle, Denise Belgorosky, Natalia Patricia Balarino, Macarena Zambrano, Marianella Sciacca, Catalina Lodillinsky, Eduardo Omar Sandes, Ana Maria Eijan
Instituto de Oncologia Angel H. Roffo - UBA

Bladder cancer (BC) is classified according to the invasion status in non-muscle invasive (NMI) and muscle invasive (MI) tumors. The progression to the invasive illness leads to radical cystectomy. Identification of novel molecules involved in tumor progression, raise the possibility to implement new therapeutic strategies in the beginning of this pathology.

Previously, we described that nitric oxide (NO) production by the inducible isoform of NO synthase (iNOS) is a bad prognosis marker in patients with BC. Using a murine BC model that express iNOS we demonstrated that iNOS inhibition with L-NAME or the stable silencing of iNOS expression by a sh-RNA (sh-iNOS), reduced tumor growth, invasion and metastases.

By a proteomic study comparing NMI MB49 and MI MB49-I orthotopic bladder tumors we selected to validate and analyze three proteins involved in migration and invasiveness processes such as

Vimentina, Carmil and Ras Suppressor Protein 1 (RSU1). The objective of the present study was to evaluate their modulation by the inhibition of NO using Western Blot (WB), Immunofluorescence (IF), Immunohistochemistry (IHC) and quantitative PCR (qPCR) techniques.

Our results showed that L-NAME reduced the pro-migration and invasiveness proteins Vimentina and Carmil and increased the pro-adhesion protein RSU1 either in MB49 and MB49-I (IHC or IF, WB and qPCR, $p<0.01$). Similar results were observed in MB49-I/sh-iNOS.

Conclusion: NO inhibition down-regulates the expression of key proteins involved in tumor progression and increases a protein related to cell attachment and adhesion. These findings added to previous results reinforce the idea that the NO inhibition could be a good therapeutic strategy for bladder tumors that express iNOS.

(1207) CANCER STEM CELLS IN THE RESISTANCE TO PHOTODYNAMIC THERAPY

Maria Laura Vilchez (1), Laura Milla (1), César Prucca (2), Beatriz Caputto (2), Viviana Rivarola (1)
(1) Dpto. de Biología Molecular. UNRC, (2) Dpto. de Química Biológica. CIQUIBIC. UNC.

Photodynamic therapy (PDT) is an oncologic treatment. It is based on the administration of a photosensitizer and its activation through visible light. The main problem of all oncological treatments, including PDT, is the occurrence of resistant cells. It is proposed that a small fraction of neoplastic cells, called cancer stem cells (CSCs), are the responsive of tumor regeneration and the resistance to the therapies. In our laboratory, we have obtained human cells of skin cancer (SCC-13) and glioblastoma (T98G), resistant to several cycles of PDT with Me-ALA. The resistant populations present characteristics of CSCs, such as a higher tumorigenic capacity, higher proliferation in 3D cultures, lower photosensitizer accumulation and higher cross-resistance to a chemotherapy drug with respect to parental population. The objective of this research was to identify and compare the expression of marker proteins of CSCs in parental population, parental population after PDT (LD50) and resistant population (flow cytometry). In SCC-13, CD44+ percentage was higher in parental cells after PDT and resistant population, respect to parental cells. In T98G was observed higher expression of CD133 marker in parental cells after PDT and in the resistant cell, comparing with parental population. Sox-2 also increased its expression in T98G (fluorescence mean 22.90 ± 3.96 U.A.) cells after PDT comparing with parental cells (15.15± 6.43 U.A.) and SCC-13 post-PDT (335.5 ±160.5 U.A.) respect to parental cells (199.50 ± 65.70 U.A.). The results encourage us to continue the studies. We will determine the degree of resistance of CSCs isolated with the markers CD133 and CD44. In addition, we will develop a strategy for elimination of these CSCs resistant to PDT through a treatment with nanoparticles conjugated to antibodies anti-CD133 and anti-CD44, in order to improve the effectiveness of PDT.

(880) *IN VITRO* SECRETOMIC ANALYSIS OF PROSTATE CANCER CELLS AND BONE PROGENITOR CELLS GROWING IN CO-CULTURE SYSTEMS

Nicolás Anselmino, Alejandra V. Páez, Sofia Lage Vickers, Javier Cotignola, Pia Valaco, Geraldine Gueron, Elba S. Vazquez
IQUIBICEN-CONICET

Currently our view of cancer has evolved to include, in addition to the transformed cells that have deregulated homeostatic mechanisms, a wide spectrum of cells of the tumor microenvironment. The dialogue established between the tumor cells and its microenvironment, is an essential determinant of the characteristics of the tumor progression. The dissemination profile of Prostate Cancer (PCa) shows tendency to develop in the bone, where tumoral cells interact with the microenvironment disrupting the bone tissue balance. This work aimed at analyzing, which soluble factors could be potential mediators of the chemical cross-talk between PCa cells and bone progenitor cells. For this purpose, we used co-culture transwell systems of PC3 (human PCa cells) with the pre-osteoclastic Raw264.7 or pre-osteoblastic MC3T3 cell lines (murine cells), where cells shared the culture media (CMs) without physical contact for 24h.

We employed mass spectrometry -nanoLC-MS/MS(Orbitrap)- for the secretome analysis of the CMs. The obtained spectra were analyzed with the Proteome Discover Software and compared with both, human and murine protein databases. Results highlight a differential profile of proteins released to the CM when tumor cells are grown in co-culture compared to controls. These results could potentially explain the altered mRNA expression levels assessed by RTqPCR in PCa cells growing in-culture, displaying significant up-regulation for HO-1 ANXA2, ANXA2R,OPG and PTHrP ($p<0.05$). Of note co-culture secretomes showcase highly bone-associated proteins released by tumoral cells such as periostin, Cartilage oligomeric matrix protein, OPN, BMP and ILGF-II, IL-7, FGF, Mx-1 -involved in prostate carcinogenesis- compared to controls, evidencing a misregulated microenvironment.

We hereby report that these results may offer a new set of potential biomarkers in addition to the existing diagnostic tests that could significantly improve sensitivity and specificity in PCa diagnosis.

(1041) INTERACTION OF TGFβ2 AND HEREGULIN FOR RAC ACTIVATION AND MIGRATION IN BREAST CANCER CELLS.

Angela Lara, Agustin Gonzalez, Eva Wertheimer
CEFYBO

Current therapies for breast cancer often fail attacking the main focus that directs it. Rac1 is a Rho-GTPase that promotes migration of breast cancer cells. We aim to study different signaling pathways that converge in Rac1 for breast cancer progression. Heregulin (HRG) is an ErbB ligand that activates Rac1 in a time-dependent manner. To determine whether a short exposure to HRG is necessary and sufficient for maintaining Rac activation over time, T-47D cells were stimulated for 5, 15 or 30min, washed to remove the stimulus and assayed for Rac activation at 1h. When HRG was supplied for 5min, Rac activation significantly decreased at 1h compared to control ($p< 0.05$). Addition of HRG immediately after washing was sufficient to recover Rac activation. When HRG was removed at 15min, slight changes on Rac activation were observed. However, removal of the conditioned medium after 30min suppressed the maintenance of Rac activation, and a second addition of HRG failed to recover the effect. We conclude that HRG is necessary for initial Rac activation and, subsequently, cells start producing autocrine factors that are necessary for maintenance of HRG-initiated Rac activation. Previous data showed that Rac activation by HRG leads to an increase in TGFβ2 expression in breast cancer cells. In fact, the TGFβ family is involved in cell migration and metastasis. Here, we show that the increase of TGFβ2 mRNA after HRG stimulation is time-dependent: it significantly increases ($p<0.05$) after 30min, with maximum at 2h. Wound healing assays reveled that TGFβ2 itself induce migration of MCF7 cells in a dose-dependent manner, with maximum at 10ng/ml. Combined addition of HRG and TGFβ2 produced the same increase on cell migration as HRG alone. These results suggest that there is a sequential relationship between the Rac1 activation peak and the maximal increase of TGFβ2. We propose that this cytokine is necessary for the maintenance of HRG-triggered phenotype of breast cancer cells.

Breast Cancer, Signaling, Heregulin, Rac, Tgfβ2.

(1043) MIGRATION CAPACITY OF BONE MARROW-MESENCHYMAL STEM CELLS FROM PATIENTS WITH ADVANCED BREAST CANCER: A NOVEL APPROACH OF BONE PRE-METASTATIC NICHE

Francisco Raúl Borzone (1), Maria Belén Giorello (1), Julieta Municoy (1), Flavia Piccioni (1), Vivian Labovsky (1), Valeria

Beatriz Fernández Vallone (2), Emilio Batagelj (3), Leonardo Feldman (4), Gustavo Yannarelli (5), Leandro Marcelo Martinez (1), Norma Alejandra Chasseing (1)
(1) Instituto de Biología y Medicina Experimental - CONICET, CABA, Argentina, (2) Institut de Recherche Interdisciplinaire en Biologie Humaine et Moléculaire (IRIBHM), Faculty of Medicine, Université Libre de Bruxelles ULB, Route de Lennik, Brussels, Belgium, (3) Departamento de Oncología, Hospital Militar Central, CABA, Argentina, (4) Departamento de Trasplante de Medula Ósea, Fundación Favaloro, CABA, Argentina, (5) Laboratorio de Regulación Génica y Células Madre, Instituto de Medicina Traslacional, Trasplante y Bioingeniería (IMeTTyB), Universidad Favaloro-CONICET, CABA, Argentina.

Recent reports indicated that self-renewal, proliferation, as well as migration capacity of bone marrow (**BM**) mesenchymal stem cells (**MSC**) are essential properties for bone regeneration processes.

We found that MSC from untreated advanced breast cancer patients (**BCP**, invasive ductal, stage III-B) have lower cloning, proliferation and osteogenic differentiation capacities than healthy donors (**HD**)-MSC. Also, BCP-MSC favoured osteoclastogenesis from BM hematopoietic precursors.

Here, we aimed to evaluate migratory capacity of MSC from BM of advanced BCP and different parameters that regulate it, which is indispensable for the processes of osteogenesis and bone vascularization. For this purpose, we studied the % of MSC that express CD146 and the level of expression/MSC (*Flow Cytometry=FC*), as well as TERT activity (*RT-PCR*), telomere length (*RT-PCR*), and intracytoplasmatic/ mitochondrial ROS production (*FC*) in MSC of BCP and HD. Also, we analyzed the expression of total and phosphorylated (P) β-catenin in these stem cells (*Western-blot and immunocytochemistry*) and the production of pro-MMP-2, active-MMP-2, SDF-1 and CCL-2 levels (*ELISA*) in conditioned media of fibroblast colony forming units (1CFU-F = 1MSC). Finally, we studied their migration capacity (*Transwell assay*).

The results indicated that BCP-MSC vs HD-MSC had: lower % of MSC-CD146(+) [p=0.0446]; decreased CD146 relative fluorescence index (p=0.0023); decreased TERT activity (p=0.0416); increased P-β-catenin expression (p=0.0001); increased P-β-catenin/ total β-catenin ratio (p=0.0410); increased total ROS levels (p=0.0286); decreased SDF-1, pro and active MMP-2 levels (p=0.0334, 0.0010, 0.0030); increased CCL-2 level (p=0.0370) and poor migration capacity (p=0.0376).

Findings suggest that alteration of MSC migration provide more insight to better defining the development of the BM and bone "pre-metastatic niche". Also, data show some possible targets aimed to restore migratory capacity of BCP-MSC.

Key words: breast cancer, bone marrow, mesenchymal stem cells, migration capacity.

(1230) **OCT-4 EXPRESSION WAS INCREASED IN RESISTANT CANCER STEM CELL-LIKE SUBPOPULATION IN COLORECTAL CANCER**

Julia Milena Gallino Fernández, Rodrigo Lloyd, Milena Batalla, Maria Belén Cerda, Florencia Giannoni, Alvaro Conde, Lucia Policastro

Radiochemoresistance of tumors has been associated with the presence of a small subpopulation of tumor cells called cancer stem cells (CSCs). These cells had been shown not only linked with high resistance to chemotherapeutic drugs but also are associated with metastatic recurrences. Embryonic markers such as Oct-4, Nanog, Sox-2 are associated with resistance to chemotherapeutic drugs in some cancer. However, little has been reported about the expression of these embryonic markers in colorectal (CRC) CSCs subpopulation. The aim of this work is the study of the mentioned embryonic marker in sensible and oxaliplatin-resistant (OXA) human CRC cancer lines, and in cultures derived of them enriched with CSC-like subpopulation, in order to detect novel markers associated to resistance in these cells. We characterized the expression of Oct-4, Nanog and Sox-2 by immunofluorescence, cell cytometer and real time-PCR in sensible or resistant human CRC cell to oxaliplatin (T-84 and HCT-116) and in cultures enriched by CSC-like subpopulation. The last cultures were obtained by growing tumor cells as colonospheres (CSPHE) in minimum medium in low adherence surfaces. On the other hand, we also measured the reactive oxygen species (ROS) levels as a characteristic associated to CSC-like subpopulation. The expression of Nanog and Sox-2 was not changed in sensible and resistant cell lines grown in monolayer or as CSPH cultures. However, the expression of Oct-4 was positive in 6-12% and 40-50% of sensible cells that were grown in monolayer or as CSPHE respectively. About chemoresistant cells lines, 40-60% and 75-85% of cells were positively for Oct-4 depending if cells were grown as monolayer or as CSPHE respectively. About ROS level, cells that were grown as CSPHE had shown significant lower levels in respect to cells that were grown as monolayer. These results showed that Oct-4 could be a promising marker to identify chemoresistant cells with CSC-like characteristics in CRC.

(3) Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, Buenos Aires, Ciudad Autónoma de Buenos Aires, Argentina.

In breast carcinomas (BC), most stromal cells are fibroblasts, and 80% of them are tumor-associated fibroblasts (TAF), characterized by increased expression of α-SMA and FSP, among others markers. One source of TAF is bone marrow (BM)-mesenchymal stem cells (MSC) and independent of the source, TAF are spindle-shaped stromal cells with negative CD34 expression. Other markers of BM-MSC such as CD105 and CD146 could be present in TAF.

In previous work we found that SSC, not associated with the vasculature, sampled from early (I/II) breast cancer patients (BCP), express RANKL and RANK at significantly higher levels vs. non-neoplastic breast tissues. Also, RANK expression in these SSC had a significant association with RANKL expression in these SSC and in tumor cells of these BCP. These SSC were CD34(-) and CD105(+) like TAF and MSC.

Recently work showed that RANKL is a critical molecule for BM-MSC clonogenic and differentiation potential, in particular osteogenic. Other authors found that RANKL soluble induced a migratory response in osteoblasts and osteoblast progenitors (MSC and pre-osteoblasts).

The aim of this study is to explore the clinicopathological significance of RANK in these SSC, as prognostic determinants of early BCP.

We conducted immunohistochemical analysis for RANK expression in these SSC of primary tumors from early BCP (invasive ductal), and analyzed their association with clinicopathological characteristics. Here, we demonstrate that the elevated level of RANK in these SSC was significantly associated with a higher risk of metastatic occurrence (0.0119). Moreover, high expression of RANK was associated with shorter disease-free survival and metastasis-free survival (p = 0.007 and 0.014).

This study is the first to demonstrate that high levels of RANK expression in SSC, not associated with the vasculature, could be used to identify early BCP with poor outcomes.

Introduction: Bladder cancer (BC) is the second most common tumor of the male urogenital tract, and an important worldwide cause of death. BC is classified as no muscle invasive (NMI) when it is localized in the urothelium and muscle invasive (MI), when it reaches the detrusor muscle. Increasing evidence has indicated the presence of cancer stem cells (CSCs) in many types of cancers, associated with cancer aggressiveness, chemoresistance and relapse. Nitric oxide (NO) is a free radical produced by enzymes called NOS. The inducible isoform (iNOS) produces high levels of NO in response to inflammatory stimuli. The expression of iNOS in human BC is a poor prognostic factor associated with increased invasion and tumor recurrence. Although there is evidence supporting the role of NO/iNOS in the promotion and progression of bladder cancer, the possibility that there are CSCs dependent on endogenous NO generation has not yet been clearly defined. The objective of this study was to evaluate the role of NO in CSC maintenance, modulating it production, using pharmacological inhibitors or silencing iNOS expression in a murine BC model.

Results: The number of CSCs, determined as spheres forming efficiency (SFE), generated by MB49-I (MI BC cell line) resulted higher than the NMI MB49 line ($p<0.05$), in concordance with the higher expression of stemness related genes, Sox-2, Oct-4 and Nanog (qPCR) ($p<0.001$). iNOS inhibition with L-NAME or 1400 W, diminished SFE in both cell lines ($p<0.05$ vs MB49;$p<0.001$ vs MB49-I), and in MB49-I, significantly inhibited the expression of pluripontency markers ($p<0.05$). Moreover, the reduction of this markers and SFE were more evident when MB49-I-shiNOS was tested ($p<0.0001$ vs MB49-I scr; $p<0.001$ vs MB49-I-scr).

Conclusion: Together, this results show that iNOS plays an important role in regulating the self-renewal ability and stemness of bladder cancer cells, and that it inhibition could be a potential therapeutic target in BC that inhibit CSCs.

(743) **SPECIFIC INHIBITION OF PROSURVIVAL FACTOR BCL-XL DISTINCTLY SENSITIZES PATIENT DERIVED GLIOMA STEM CELL LINES TO CHEMOTHERAPY DRUGS**

Germán Ignacio Nogueiras, Verónica Alejandra Furmento, Olivia Morris Hanon, Gustavo Emilio Sevlever, María Elida Scassa, Guillermo Agustín Videla Richardson

Laboratorios de Investigación Aplicada a Neurociencias, LIAN, FLENI.

High-grade gliomas are the most prevalent and lethal primary brain tumors. They display a hierarchical arrangement with a population of self-renewing and highly tumorigenic cells called cancer stem cells. These cells are thought to be responsible for tumor recurrence, which make them main candidates for targeted therapies. High levels of anti-apoptotic molecules in cancer cells have been shown to both result in resistance to chemotherapy and promotion of unrestrained growth. Herein, we examined the sensitivity of patient derived glioma stem cell enriched cell lines (GSC-ECLs) to a panel of chemotherapy drugs. Flow cytometric analysis of PI staining revealed that treatment with temozolamide (TMZ) (50-500μM) or lomustine (CCNU) (20-200μM) for 7 days increased cell death in a dose-dependent manner ($p<0,05$) while no significant change in GSC-ECLs viability was observed upon vincristine (VCR) (0.5-5μM) exposure. Also, by RT-qPCR and Western blot we determined that GSC-ECLs express higher levels of anti-apoptotic Bcl-xL and Bcl-w and lower levels of Bcl-2 than untransformed neural progenitors ($p<0,05$). Pro-survival Bcl-2 family members counteract apoptosis by sequestering BH3 domains. Thus, to gain insight into the mechanisms that control GSC-ECLs decisions in response to chemotherapy agents, we attenuated their anti-apoptotic threshold using small molecules that mimic BH3 motifs. ABT-263 preferentially targets Bcl-2, Bcl-xL and Bcl-w while WEHI-539 targets only Bcl-xL. Using these agents and small interference RNA-mediated gene silencing we studied the contribution of Bcl-xL, Bcl-w and Bcl-2 in cell survival. We found that BH3-mimetic treatment or Bcl-xL gene silencing similarly exacerbate cell death triggered by TMZ or CCNU and render cells sensitive to VCR in a cell line-dependent manner. Given the intertumor heterogeneity present in high-grade gliomas, the knowledge of GSC-ECLs distinct dependence on Bcl-xL activity may help the development of tailor-made therapies.

Keywords: glioma stem cells, BH3-mimetic, drug resistance

(1102) **WHOLE EXOME SEQUENCING ANALYSIS OF MELANOMA SUSCEPTIBILITY LOCI, FROM GERMLINE TO PRECURSOR AND TUMOR LESIONS - A CASE REPORT**

Ana Mordoh (1), María Marcela Barrio (1), Mariana Aris* (1), José Mordoh* (1,2)

(1) Centro de Investigaciones Oncológicas-FUCA (CABA, Argentina), (2) Instituto Médico Especializado Alexander Fleming; Fundación Instituto Leloir-IIBBA-CONICET (CABA, Argentina.)

The impact of melanoma susceptibility loci throughout tumor evolution from precursor benign nevi to cutaneous melanoma is unknown. The aim of this work was to analyze susceptibility loci at different stages of progression in a cutaneous melanoma patient. *Methods:* Formalin-fixed paraffin embedded biopsies from primary tumor, its associated nevi and lymph node metastasis were sectioned by laser capture microdissection and DNA was isolated. DNA from PBMC was used as germinal reference. Whole exome sequencing was performed (Agilent SureSelect Human All Exon V5, Illumina HiSeq 4000, 100X effective mean depth per sample). A panel of reported loci associated to melanoma susceptibility was searched in germline and lesions; variants allele frequencies were determined for each sample. *Results:* A total of 56 variants covering 28 genes in 13 chromosomes were found in germline and all lesions. 15/56 variants were homozygous. Variants that required LOH to be functional and found heterozygous in lesions samples were not considered as putative susceptibility loci in this patient. Only tumor suppression variants found to be homozygous, heterozygous with haploinsuficiency or oncogenes detected in all samples might have had a role in tumor development and progression. These variants included genes related to hallmarks of cancer such as proliferation (CDK4), abolition of tumor growth suppression (PTCH1), escape from cell death (CASP8), invasion and metastasis (CTSS), inflammation (CPNE7), genome instability and mutations (ATM), and cell replicative immortality (CLPTM1L). *Conclusion:* combined analyses of melanoma susceptibility loci in germline and lesions at different stages of progression provide insight of trunk variants involved in tumor evolution, with impact in patient´s outcome.

(711) **COMBINED RADIOTHERAPY AND HISTAMINE FOR EFFECTIVE TREATMENT OF BREAST CANCER**

Diego Martinel Lamas (1), Melisa Nicoud (1), Helena Sterle (1), Noelia Massari (2), Verónica Herrero Ducloux (2), Graciela Cremaschi (1), Horacio Blanco (3), Vanina Medina (1)

(1) Instituto de Investigaciones Biomédicas (BIOMED, UCA-CONICET), Buenos Aires, Argentina. (2) Facultad de Ciencias Naturales y de la Salud, Universidad Nacional de la Patagonia San Juan Bosco, Chubut, Argentina. (3) Hospital Municipal de Oncología Marie Curie, Buenos Aires, Argentina.

Previous studies demonstrated that histamine enhanced ionizing radiation (IR)-induced response *in vitro* and *in vivo* in human triple negative breast cancer (TNBC) and melanoma models. The aim of this work was to further explore the effect of the combination treatment of histamine and *gamma* IR on tumor immunity, employing a syngeneic TNBC model, with intact immune system, developed in

Balb/c mice with 4T1 cells. Proliferation, apoptosis and oxidative damage studies were performed. Tumor infiltrating lymphocytes and lymphocyte subpopulations in spleen were evaluated by FACS.

Results indicate that histamine potentiates IR response mainly *in vivo*. Radiation administered as 3 doses of 2 Gy in consecutive days reduced tumor growth and weight. Treatment of 4T1 tumor-bearing mice with histamine (1 mg/kg.day) injected *sc* starting 1 day before irradiation until the end of the experiment, potentiated IR-induced decrease in tumor growth ($P<0.05$) and also reduced splenomegaly. The analysis of the distribution of the immune cell subsets showed decreased CD4+ and CD8+ T together with reduced CD19+ B lymphocytes in both histamine-treated and non-treated irradiated tumors. Conversely, histamine treatment increased the percentages of NK cells (4.6±0.8 vs. 1.7±0.3, $P<0.01$) and myeloid derived stem cells (26.7±3.8 vs. 8.9±1.0, $P<0.05$) in irradiated tumors. Non-significant changes in the percentage of lymphocyte populations were observed in spleen of tumor-bearing animals. We conclude that histamine could improve radiation therapy in part by modulating tumor immunity.

(1104) **EZH2 AS A TARGET OF PROGESTERONE RECEPTOR-MEDIATED BREAST CANCER GROWTH**

Mauro Ezequiel Cenciarini (1), Matías Federico Amasino (1), Mara De Martino (1), María Florencia Chervo (1), Violeta Chiauzzi (1), Yanming Wu (2), Kexin Xu (2), Felipe Gustavo Gercovich (3), Ernesto Gil Deza (3), Sandra Ares (3), Roxana Schillaci (1), Patricia Virginia Elizalde (1), Cecilia Jazmín Proietti (1)

(1) Instituto de Biología y Medicina Experimental, CONICET, Buenos Aires, Argentina, (2) University of Texas Health Science Center, San Antonio, Texas, USA, (3) Instituto Oncológico Henry Moore, Buenos Aires, Argentina

On the basis of Estrogen Receptor (ER) presence, breast cancer (BC) patients are treated with selective ER modulators (SERMs) such as tamoxifen. However, approximately 40% of women receiving TAM experience tumor relapse. We and others have previously reported Progesterone Receptor (PR) participation in BC growth. We therefore propose that, being blocked ER, PR may take control of tumor growth, progression and endocrine resistance. We have described that the progestin medroxiprogesterone acetate (MPA) induces the interaction between PR and EZH2 to promote transcriptional repression of tumor suppressor GATA3. EZH2, a histone methyltransferase, is often overexpressed in different types of cancers and associated with poor overall survival. The objective of this work was to study the role of EZH2 in MPA-induced BC growth. In vitro studies were carried out in the T47D human BC cell line and in primary cultures of the MPA-dependent C4HD tumor. Firstly, MPA (10 nM) induced EZH2 expression after 18 and 24 h of treatment, seen by increased levels of both mRNA (qPCR, $p<0.05$) and protein (SDS-PAGE/WB). RU486, a PR antagonist, prevented these effects. Interestingly, when EZH2 was knocked-down by a specific siRNA or when EZH2 activity was specifically inhibited by GSK126 (5 uM), MPA-induced cell proliferation was prevented ($p<0.001$). In a pre-clinical study, 12 BALB/c mice carrying C4HD tumors (via sc) were randomly separated in two groups, and injected via ip for 14 days with either vehicle (captisol 20%) or GSK126 (50 mg/kg/day). Blockage of EZH2 activity diminished MPA-induced tumor growth ($p<0.001$). Lastly, EZH2 protein expression was analyzed by IHC in a cohort of 118 ER+/PR+ BC patients treated only with tamoxifen. Patients with higher EZH2 expression showed to have lower DFS probability ($p=0.0099$). These results show a key role of EZH2 in progestin-induced breast cancer and point it out as a possible novel therapeutic target for TAM-resistant breast cancer.

Key words: breast cancer, progesterone receptor, EZH2, GSK126, tamoxifen

(509) **PROTEIN SIGNATURES THAT ALLOW PROPER METAL RECOGNITION AND SIGNAL TRANSDUCTION IN MerR METALLOREGULATORS**

Julián Ignacio Mendoza, Julián Lescano, Fernando C Soncini, Susana K Checa

Instituto de Biología Molecular y Celular de Rosario (IBR), CONICET-UNR, Argentina.

Transcriptional regulation is the main cellular mechanism bacteria employ to control homeostasis/resistance to essential and harmful metal ions. Our group focuses on metalloregulators of the MerR family, dimeric proteins that detect the ions in the cytoplasm and activate transcription of specific transporters or detoxification enzymes to eliminate the intoxicant. Among them, two groups with similar structure can be clearly distinguished depending on the charge (+1 or +2) of the metal ion they sense. Previously, we discerned the molecular bases that allow GolS, a *Salmonella* specific sensor, to discriminate Au(I) from other metal ions including Cu(I) or Ag(I), or divalent ions. We found that two residues from the metal binding loop (MBL) between the two coordinating cysteines (A113 and P118) are crucial for Au discrimination, while a single serine residue (S77) that is located near the metal coordination environment is essential from excluding +2 charge metals from the binding site. Here, we analyzed how the size and identity of the residues of the MBL determine proper recognition of metal ions and transcriptional activation. We swapped the MBL of GolS or CueR (the paralogous non-selective monovalent metal ions sensor) for the same region of ZntR or MerR, two representatives of the divalent metal ion sensor group, and analyzed the response of the new variants to different monovalent (Au and Cu) or divalent (Hg, Cd, Pb and Zn) metal ions by measuring transcriptional activation of specific reporter genes. Our results suggest that besides the presence and proper location of essential ligands, the size of the metal binding loop is the main determinant of proper metal recognition and signal transduction that allow activation of transcription of target genes.

Keywords: Metals,Transcriptional regulation, Metalloprotein, MerR regulator

(1841) **ANTI- *Helicobacter pylori* ACTIVITIES OF *Origanum vulgare* AND *Larrea divaricata* CAV EXTRACTS IN VITRO.**

Florencia Ferramola, Ángel Gabriel Salinas, Andrea Celeste Arismendi Sosa, María Aída Mattar Domínguez, Alba Edith Vega

Área de Microbiología. Facultad de Qca, Bqca y Fcia. Universidad Nacional de San Luis. *Argentina.*

Helicobacter pylori is a gram-negative bacillus and is the cause of peptic ulcer disease and gastric cancer. Due to antibiotic resistance, there is great interest in the search for new therapies. Urease and Flagella are virulent factors that are required for the colonization and survival of *H. pylori* in the human stomach. *Origanum vulgare* (Orégano) and *Larrea divaricata* Cav. (Jarilla) are plants known for their properties in folklore medicine. The aim of this work was to investigate the effects of *O. vulgare* and *L. divaricata* extracts on antimicrobial activity and inhibition of urease and flagella activities in *H. pylori* strain. In this study, the antibacterial activity of both aqueous extract against *H. pylori* strain was assayed according to CLSI guidelines (CLSI, 2007). The extracts were diluted to obtain the final concentrations from 10 to 0,009 mg/ml for each. Serial dilutions of Amx (Sigma-AldrichCo., StLouis, MO) were used as a control in the susceptibility test. Bacterial suspension was adjusted to a scale of 0.5 McFarland standard ($1x10^8$ CFU/ml). Minimal inhibitory concentration (MIC) was measured by determining the lowest amount of extract or antibiotic needed to inhibit the visible growth of the microorganism. The reference strain HP146128 was treated with sub-inhibitory concentrations of Orégano extract (0,5 mg/ml) and Jarilla extract (1 mg/ml) and was incubated for 26h at 37°C in microaerophilic atmosphere. The gene expressions were determined by RT-PCR using 16s RNA as housekeeping gene. The results obtained showed that the MIC of Orégano and Jarilla were 1,25 mg/ml and 2,5 mg/ml respectively. Orégano extract down-regulates the ureA gene and fla gene expressions; while the Jarilla extract showed no decrease in the expression of the same genes to the concentration assayed. The use of Orégano extract can contribute as alternative

and complementary medicines, safe and less costly in the treatment of *H. pylori* infections.

(1491) **SYNTHETIC BIOLOGY FOR THE DEVELOPMENT OF A CYANOBACTERIAL HIGH-VALUE-MOLECULES PRODUCTION PLATFORM**

Julia Roulet (1), Arnaud Taton (2), Michael D. Burkart (3), Hugo C. Gramajo (1), Ana L. Arabolaza (1)
(1) Instituto de Biología Molecular de Rosario (IBR). (2) Division of Biological Sciences, University of California, San Diego (UCSD). (3) Department of Chemistry and Biochemistry University of California, San Diego (UCSD

Cyanobacteria are the only prokaryotes that perform plant-like oxygenic photosynthesis and convert sunlight-derived energy into biomass. They possess several advantages as hosts for biotechnological applications, including simple growth requirements, ease of genetic manipulation and robust high-scale production. At present, many bioindustrial processes rely on the fermentation of heterotrophic bacteria to produce various fine chemicals. Nevertheless, the economic viability of these production schemes is limited by the cost of carbon substrates used in the fermentation processes. Cyanobacteria, endowed with photosynthesis system to fix carbon dioxide into reduced form, are ideal biosynthetic machinery for sustainable production of various chemicals and biofuels. In this context, we aim to develop a cyanobacterial platform for the production of high value molecules of industrial interest. For this purpose, and as a proof of concept, we designed and constructed recombinant cyanobacteria strains capable of producing methyl-branched chain lipids (MBL), which have exceptional physicochemical properties for their application in the bio-lubricants, pharmaceuticals and cosmetics industries.

The construction of different heterologous pathways for the biosynthesis of the substrates and the final products was done using a combinatorial modular design. After the recombinant-cyanobacteria strains were obtained, we tested if the enzymes of each pathway were expressed and finally we carried out different bioconversion assays to test if the desired products were synthesized. These bioconversion assays demonstrated that the cyanobacterial strains successfully produced MBL.

In summary, we have developed a cyanobacterial high-value-molecules production platform with a modular-functional design that allows a versatile, interchangeable and combinatorial construction of the desired cyanobacterial strain.

(174) **BOVINE MACROPHAGES INTRACELLULAR TRAFFIC OF *Leptospira interrogans***

Ariel Nagel, Federico Blanco, Maria José Gravisaco, Cristina Vázquez, Vanina Varni, Karina Caimi
Instituto de Biotecnología, CICVyA, INTA Castelar

Pathogenic leptospires are able to infect humans and many domestic and wild animals. This bacterium can survive and grow in animal tissues by escaping natural defense mechanisms. We have recently obtained the whole genome sequence of a representative strain from a major clon circulating in Argentina that causes bovine reproductive losses The objective of this study was to analyze the cellular traffic between this virulent strain and its attenuated counterpart in bovine macrophages to understand their differential virulence.

We have infected bovine macrophages derived from peripheral blood mononuclear cells (PBMCs) with stained leptospires from both virulent (P1) and attenuated (P19) strains. Infections were analyzed using flow cytometry and confocal microscopy. In order to evaluate the cell entrance we have used cytochalasine D (cytoD) as a phagocytosis inhibitor. The intracellular localization was studied using Lysotracker and immunofluorescence with LAMP-3.

Both techniques showed a higher number of P1 inside the cell compared with P19. Cells pre-treated with cytoD showed 50% less intracellular P1 than untreated cells. No significative difference was observed for the attenuated strain with cytoD. The intracellular colocalization of Lysotracker with P1 was significantly higher than the observed for P19, both in cytoD treated and untreated cells. The same was observed for the colocalization of LAMP-3 with both strains. Particularly, in cytoD treated cells, the colocalization of Lysotracker with P1 was 50% lower than in untreated cells.

The ability of leptospires to invade bovine macrophages was confirmed and the virulence of P1 could be explained by the higher amount of bacteria inside the macrophages in comparison with P19. Our results allowed us to postulate a possible intrinsic mechanism of cellular entrance not dependent of phagocytosis for P1. This could lead to a possible evasion of leptospires from the innate bovine macropaghes mechanisms of bacteria control.

(1544) **PARTIAL PURIFICATION OF ANTIMICROBIAL PEPTIDES ACTIVE AGAINST FOOD BORNE PATHOGENS**

Lucía Lanza, Silvia Adriana Navarro, Augusto Bellomio, Chalón Miriam Carolina
Instituto Superior de Investigaciones Biológicas INSIBIO-CONICET-UNT, Tucumán, Argentina

Bacteriocins are small, ribosomally synthesized antimicrobial peptides that kill bacteria closely related to the producer strain. Hybrid bacteriocins were made by the fusion of genes encoding Enterocin CRL35 (*munA*), Pediocin PA-1 (*pedA*) and Microcin V (*cvaC*) separated by a hinge region. These bacteriocins were constructed in order to obtain peptides with broad antimicrobial spectrum. The aim of this work was to purified different hybrid bacteriocins and microcins available in our laboratory. Microcin E492, Microcin V and Microcin H47 were obtained from supernatants of the producer strains. Hybrid bacteriocins with different hinge regions (Ent35-GGG-Mccv, PedA-GGG-MccV, PedA-GIG-MccV) were purified by disruption of the producing strains and subsequent precipitation of the proteins with 40-50% $(NH_4)_2SO_4$. The cellular extracts were loaded onto a C18 chromatography cartridge, eluted with acetonitrile and then were concentrated. The antimicrobial peptides were found to be active against different food borne pathogens such as *Listeria monocytogenes*, *Escherichia coli* O: 157, *Salmonella enterica* serovar pullorum and gallinarum. Serial double dilutions of the partially purify peptides were performed. Antibiotic activity units (AU/ml) were calculated as the reciprocal of the highest dilution showing growth inhibition halo against *E. coli* MC4100. The antimicrobial peptides have potential biotechnological applications as food biopreservative and in the pharmaceutical industry.

Keywords: bacteriocins, biopreservative, food borne pathogens.

(1488) **RNA-SEQ TRANSCRIPTIONAL PROFILING OF *Herbaspirillum seropedicae* IN RESPONSE TO SUFFICIENT AND HIGH PHOSPHATE CONCENTRATION**

Mariana Grillo Puertas (1), Vania Carla Pankievicz (2), Michelle Tadra-Sfeir (2), Raúl Osvaldo Pedraza (3), Viviana Andrea Rapisarda (I), Emanuel Maltempi Souza (2)
(1) INSIBIO, CONICET-UNT, Tucumán. (2) Dep. Biochem. and Mol. Biol., U
FPR, Curitiba, Brazil. (3) Inst. de Microbiología Agrícola, FAZ-UNT, Tucumán

Herbaspirillum seropedicae is a diazotrophic and endophytic bacterium associated with important agricultural crops, promoting plant growth and increasing productivity. Its agricultural use requires studies on its physiological response to prevailing levels of nutrients such as phosphate (Pi). It has been previously reported in different bacteria that environmental Pi modulates the levels of intracellular polyphosphate (polyP), a molecule that plays important roles in microbial metabolism. The aim of this work was to evaluate the intracellular polyP levels and the differentially expressed genes in *H. seropedicae* grown in sufficient or high Pi conditions. *H. seropedicae* SmR1 was grown in NFbHN-malate medium modified with 5 or 50 mM Pi; culture absorbance at 600nm and polyP levels were measured at different times during 24 h. Results showed that cultures grown in high Pi medium reached higher cell densities than cultures grown in sufficient Pi media and maintained high polyP levels in stationary phase. To analyze if these differences in pol-

yP levels could generate changes in gene expression, mRNA from cell grown in different media was purified and used for RNA-seq profiling. Comparison of RNA profile between sufficient and high Pi conditions revealed that 620 genes were differentially expressed, being 53 and 43% repressed and induced by high Pi, respectively. Most of the induced genes in the high Pi condition were involved in energy production process, two component regulatory systems, amino acid transport and metabolism, chemotaxis and inorganic ion transport and metabolism. The ability to respond to environmental signals which modulates polyP production could be critical in diverse aspects of *H. seropedicae*.

(1753) **ROLE OF DIFFERENT COUPLING CHEW PROTEINS IN THE CHEMOTAXIS-RELATED PATHWAYS OF THE HYDROCARBON-DEGRADING STRAIN *Halomonas titanicae* KHS3**

Fernando E Ramos Ricciuti, Rocio S Balmaceda, M Karina Herrera Seitz, Claudia A Studdert
Instituto de Agrobiotecnología del Litoral - Santa Fe

In the canonical *E. coli* chemotaxis pathway, chemoreceptors transmit information from the extracellular medium to an associated histidine kinase (CheA), through a coupling protein (CheW). Many environmental bacteria possess more than one chemosensory pathway. The protein components show a high conservation and mechanisms that avoid crosstalk between the different pathways are not clear yet.

Halomonas titanicae KHS3 was isolated from Mar del Plata harbor. It can grow using polyaromatic hydrocarbons as the sole carbon source and displays chemotactic behavior toward these compounds.

Two chemotaxis-related systems were identified in its genomic sequence. Cluster 1 has a canonical organization, similar to the *E. coli che* cluster. On the other hand, cluster 2 shows a different gene organization including a diguanylate cyclase protein and two CheW-like coupling proteins.

The aim of this work was to investigate the properties of the different CheW proteins. The three proteins were modelled using Swiss-model software. Both *Ht* CheW1 and CheW2 showed a structure similar to *E. coli* CheW whereas *Ht* CheW3 displayed an structure that deviated from the conserved one, suggesting a different role.

CheW1 and CheW2 were expressed in *E. coli* cells. CheW1, from cluster 1, complemented chemotaxis function in an *E. coli* strain lacking native CheW in soft agar plates, indicating that it fulfills a similar role in complexes that control flagellar rotation. When expressed at very high levels, it interfered with chemotactic function, consistent with the ability of CheW proteins to interact with chemoreceptor dimers and disrupt important receptor-receptor interactions.

In contrast, CheW2 failed to restore chemotactic function, and did not interfere with *E. coli* chemotaxis, even when overexpressed. This indicates that CheW2 does not interact with *E. coli* chemoreceptors, suggesting that it has specificity determinants for proper interactions with cognate receptors.

(823) **USE OF SUICIDE PROBES TO STUDY CLASS II BACTERIOCINS MECHANISM OF ACTION AGAINST A RECEPTOR-FREE HOST**

Natalia Soledad Ríos Colombo (1), Miriam Carolina Chalón (1), Augusto Bellomio (1)
(1) Instituto Superior de Investigaciones Biológicas (INSIBIO).

The increasing resistance to common antibiotics is highly worrisome, thus, it has led to the study of alternative antimicrobials as a primary concern. Bacteriocins are a promising solution to this problem and the understanding of their mechanism of action is fundamental for development of new variants with potential use in the pharmaceutical industry. Class II bacteriocins are unmodified membrane-active peptides that act over a narrow spectrum of bacterial targets. They are believed to bind a specific receptor on the membrane that would participate in the formation of a pore, leading to membrane permeabilization and cell death. In order to reveal whether or not the pore structure involves a specific receptor, we designed chimeric peptides fusing the bitopic membrane protein EtpM with different class II bacteriocins: enterocin CRL35 (Ent35), pediocin PA-1 (PedA-1) and microcin V (MccV). We chose *E. coli* as an expression host because this bacterium is naturally insensitive to Ent35 and PedA-1, since their specific receptor Man-PTS is not present on its inner membrane. In addition, an *sdaC* mutant *E. coli* strain was employed as a receptor-free host for MccV, as it does not express SdaC, the specific membrane receptor for this microcin. If the fusion EtpM-bacteriocin kills the expressing host cell, it would mean that the specific receptor could be dispensable for the final step of membrane disruption. As these constructs exert a lethal effect when they are expressed, they are called “suicide probes”. This hybrid proteins EtpM-Bacteriocins were heterologeously expressed in *E. coli* and *E. coli* ΔsdaC respectively, and the results suggest that, indeed, the specific receptor would act simply as docking molecule and it would not participate in pore formation mechanisms. The effect of these suicide probes in some membrane properties is also analyzed.

(1844) **DISSECTION OF VIRULENCE-ASSOCIATED TRANSCRIPTIONAL NETWORKS IN *Brucella*: SEEKING FOR NEW REGULATORY PROTEINS THROUGH BIOINFORMATIC, BIOCHEMICAL AND MOLECULAR APPROACHES**

Gabriela Sycz, Rocío Tau, Hernán Bonomi, Angeles Zorreguieta, Rodrigo Sieira
Fundación Instituto Leloir.

In facultative intracellular bacteria of the genus *Brucella*, significant progress has been made in identifying virulence factors. However, the genetic program orchestrating the *Brucella* intracellular adaptation process is still poorly understood. In this regard, our group recently identified the regulon of VjbR, a transcription factor known to play a major role in the pathogenesis of *Brucella*. Our ChIP-seq and RNA-seq analyses showed that VjbR controls bacterial functions relevant for survival during the initial stages of the intracellular infection, and revealed that VjbR indeed acts as a global regulator exhibiting a large amount of binding sites across the *Brucella* genome. However, further analysis of our data indicated that the VjbR transcriptional network is highly complex. For instance, we found that VjbR failed to bind to many genomic positions containing conserved VjbR-binding motifs, which suggested the possible existence of competitors that prevent binding of VjbR to specific promoters under the assayed conditions. To explore this possibility, we developed a bioinformatic method that allowed us to identify conserved sequences adjacent to VjbR-binding motifs that failed to bind VjbR *in vivo*, which could act as binding sites for competitor transcription factors. EMSA analysis of one of such specific promoters showed that in the absence of competitors, VjbR alone was able to interact *in vitro* with its target DNA sequence. Moreover, in *Brucella* crude extracts we detected two proteins able to bind to the analyzed promoter. Using biochemical and molecular methods we isolated one of these proteins, wich was identified as a transcription factor known to coactivate expression in other direct targets of VjbR. Determination of the second DNA-binding protein, however, will requiere further work. In summary, here we present a pipeline suitable to identify possible competitor and/or coactivator transcription factors in complex transcriptional regulatory networks.

(849) **CHARACTERIZATION OF SECONDARY METABOLITE BIOSYNTHESIS PATHWAYS IN *S. EUROCIDICUS*.**

Bárbara Aylén Bercovich (1), Romina Celada (2), Guillermo Labadie (2), Daniel Kurth (3), Hugo Gramajo (1), Eduardo J. Rodriguez (1)
(1) Instituto de Biología Molecular y Celular de Rosario (IBR), (2) Instituto de Química Rosario (IQUIR), (3) PROIMI.

Streptomyces eurocidicus produces at least three secondary metabolites, azomycin, eurocidin and tertiomycin, which its biosynthesis pathways are unknown. Azomycin is a broad-spectrum antibiotic belonging to the group of nitroheterocyclic compounds. Eurocidin

is a pentaene macrolide with antifungal activity. And Tertiomycin is an antibacterial compound from the spiramycin family with activity against Gram-positive bacteria, but the structure is still unknown. With the aim of study the biosynthetic pathwayof these metabolites, we have first validated the production of each of the using *S. eurocidicus* NRRL B-1676 strain. In liquid media culture it was found that eurocidin is produced in the exponential phase while both azomycin and tertiomycin are produced in the stationary phase of growth. Surprisingly, it was found that *S. eurocidicus* has a compound, presumably eurocidin, with a strong fluorescence that stains colonies on solid and liquid media. The identity of each compound was determined by TLC observed by UV at 254/302 nm and by p-anisaldehyde staining, or by high resolution LC-MS. In turn, the activities of each spot observed were determined by inhibition against *Bacillus subtilis* or *Saccharomyces cerevisiae*. Then, we have sequenced the *S. eurocidicus* NRRL B-1676 genome by 100bp paired-end reads using Ilumina technology. Analysis of the genome sequence allowed identifying putative gene cluster for each metabolite using bioinformatic tools. To validate these gene clusters we are constructing knock-out strains by homologous recombination or by UV mutagenesis. Thus, mutant strains for eurocidin gene cluster were obtained and it was found that they lost antifungal activity and are not fluorescent. New mutant strains for the other pathways are being constructed.

(554) A FUNCTIONAL CHARACTERIZATION OF AMP-ACTIVATED PROTEIN KINASE IN *Trypanosoma cruzi*

Tamara Sternlieb, Patricio Dino Genta, Alejandra Cecilia Schoijet, Nadia Maricel Barrera, Milena Massimino Stepñicka, Guillermo Daniel Alonso
INGEBI - CONICET - UBA

The AMP-activated protein kinase (AMPK) is a heterotrimeric enzyme involved in maintaining energy homeostasis in response to different stresses in many organisms. Sequence and structure of its subunits may change between organisms, but they maintain the same function. The α subunit contains a N-terminal kinase catalytic domain, the β subunit acts as a scaffold and intervenes in the localization of the complex and the γ subunits binds AMP. During the transition from the mammal host to the insect vector, *Trypanosoma cruzi* suffers nutritional stress from the absence of glucose in the insect's midgut. The ability to respond to this stress, allows the parasite to differentiate and survive. Recently, it was shown that *Trypanosoma brucei* AMPK is involved in surface protein expression changes in response to nutritional stress and differentiation.

We identified four candidate genes for the AMPK subunits of *T. cruzi* (α1, α2, β and γ). Each of these subunits was capable of reverting the 'glucose dependent' phenotype of *S. cerevisiae* conditional mutants alternatively lacking one subunit of the AMPK ortholog SNF1. Also, we overexpressed the α1, β and γ subunits with a hemagglutinin (HA) Tag in CL Brener epimastigotes and evaluated their localization and possible post-translational modifications. Western blots using anti-PhosphoAMPK antibody showed specific stripes corresponding to the expected MW of the alpha subunits. These stripes are reduced in intensity or completely deleted with Lambda phosphatase treatment. Also, epimastigotes treated with an AMPK specific activator show a shift in the intensity pattern of the stripes. Thus, the phosphorylation pattern of the α subunits can be modified *in vivo*. RT-PCR assays also revealed the endogenous α2 mRNA, but not the α1 mRNA in epimastigotes. Our results show, for the first time, the presence of an AMPK ortholog in *Trypanosoma cruzi*. In the future, we aim to discover its role in the life cycle and stress responses of this parasite.

Keywords: AMPK, stress response, AMP, signaling, transduction pathway

(608) IN VIVO EVALUATION OF THE BIOLOGICAL FUNCTION OF AN AMP-ACTIVATED PROTEIN KINASE ALPHA SUBUNIT IN *TRYPANOSOMA CRUZI*

Patricio Dino Genta, Tamara Sternlieb, Nadia Maricel Barrera, Milena Massimino Stepñicka, Guillermo Daniel Alonso, Alejandra Cecilia Schoijet
INGEBI; CONICET; UBA.

The AMP-activated protein kinase (AMPK) is a heterotrimeric evolutionarily conserved enzyme that typically functions as a metabolic sensor and generates changes in energy homeostasis, through transcriptional and metabolic reprograming. In parasitic protozoa, such as *Trypanosoma cruzi*, energy sensing is crucial since they must go through sudden environmental changes during the passage through its different stages. AMPK can also influence other cellular processes such as mitochondrial activity, autophagy, endoplasmic reticulum stress, and apoptosis. This protein kinase is composed of the catalytic subunit α and two regulatory subunits β and γ.

Using conserved domains and secondary structure analysis, we have been able to identify four candidate genes corresponding to two a subunits, named TcAMPK±1 and TcAMPK±2, and ² and ³ subunits, named TcAMPK² and TcAMPK³ respectively. In the present work we have focused on the characterization of TcAMPK±1; for this goal we subcloned into the pRIBOTEX vector the putative orthologous gene of *T. cruzi* (TcAMPKα1), to which we added an HA tag to perform further experiments.

To study its expression, we first evaluated its transcription through RT-PCR and the expression of the HA-fussed protein was confirmed in the soluble fraction by subcellular fractionation and subsequent western blot. After confirming its correct transcription and translation we demonstrated its localization in granules distributed in the cytoplasm by indirect immunofluorescence using an anti-HA antibody.

In the present time, we are assessing epimastigote cultures growth of wild type and TcAMPKalfa overexpressing parasites, with or without Compound C (Dorsomorphin) which is a potent and specific inhibitor of the AMPK activity. These studies will allow us to identify the biological function of this protein, which may be essential to maintain the energy homeostasis of the cell and to complete their life cycle.

Keywords: Chagas disease, metabolic sensor, energy homeostasis, AMPK.

(1410) STUDY OF SMALL GTPASE RAB11 IN *Leishmania mexicana.*

Nicolás Mendez, Giannina Carlevaro, Juan Mucci
Laboratorio de Inmunología Molecular

Leishmaniasis is a human disease produced by species of the genus *Leishmania*, that infect 1 million individuals per year. As *Trypanosoma cruzi* and *Trypanosoma brucei*, *Leishmania* parasites express surface GPI-anchored virulence factors with key roles in infection.

In *T. cruzi*, the small GTPase Rab11 and the contractile vacuole complex (CVC) are key elements in the transport pathway of these proteins to the surface, whereas in *T. brucei* Rab11 mediates endosomal recycling, as in higher eukaryotes. The function of Rab11 in *Leishmania* has not been studied yet. To investigate this, we overexpressed (OE) a *GFP-LmRab11* fusion protein gene in *Leishmania mexicana*, cloned in the pNUS-nGFP vector. Expression was verified by western blot or flow cytometry and the overexpressed populations showed no growth differences with wild type and GFP^{OE} control parasites.

We found that the GFP-Rab11 signal is localized within a small intracellular region, as in *T. cruzi*, compatible with the location of the CVC. We observed morphological changes in Rab11^{OE} parasites with respect to controls. Scanning electron microscopy revealed that Rab11^{OE} parasites have less extracellular vesicles than the wild type.

To explore the effects of interfering with the Rab11 pathway, we transfected *L. mexicana* with mCherry-Rab11 "dominant-negative" (DN): an enzymatically inactive version of the GTPase by the S21N substitution. Despite numerous attempts, it was not possible to obtain Rab11DN^{OE} populations. However, simultaneous transfection with GFP-Rab11 was successful. As expected, we observed that the active GTPase localizes in the CVC region, while the Rab11DN signal is distributed throughout the cytoplasm. These results show that expression of Rab11DN is deleterious, as it was only possible by co-expression in Rab11^{OE} background.

This effect is not observed in *T. cruzi* and suggests that Rab11DN interferes with vital processes in *Leishmania* biology.

Keywords: Rab11, Leishmania mexicana, Contractile Vacuole Complex.

(465) **STUDYING THE ROLE OF NUCLEOSIDE DIPHOSPHATE KINASE 1 FROM *Trypanosoma cruzi* IN DNA INVOLVING MECHANISMS**

Melisa Saye, Chantal Reigada, Fabio Digirolamo, Edward Valera-Vera, Claudio Pereira, Mariana Mirada

Universidad de Buenos Aires, Facultad de Medicina, Instituto de Investigaciones Médicas A. Lanari, Buenos Aires, Argentina; Consejo Nacional de Investigaciones Científicas y Técnicas, Universidad de Buenos Aires, Instituto de Investigaciones Médicas (IDIM), Laboratorio de Parasitología Molecular, Buenos Aires, Argentina.

Nucleoside diphosphate kinases are multifunctional enzymes that participate in many cellular processes besides their housekeeping function of maintaining intracellular pools of di and tri phosphate nucleotides. TcNDPK1 is an isoform of the enzyme present in Trypanosoma cruzi, the parasite that causes Chagas Disease. Among the multiple possible functions, several evidences associate TcNDPK1 with DNA processing, for example, the in vitro ability of binding nucleic acids and its nuclease activity. In the present work we evaluate the role of TcNDPK1 in DNA involving processes such as DNA repair using heterologous gene expression systems and over expression in epimastigote cells. We found that bacterias expressing the enzyme decreased five times the spontaneous mutation rate respect to controls, measured by counting rifampicin resistant colonies. In addition, yeasts lacking the endogenous gene YNK1 (YNK1-) but expressing TcNDPK1, grew more efficiently, tolerated high hydrogen peroxide concentrations (IC_{50} of 21.2mM and 6.3mM respectively) and were less sensible to UV irradiation *than control*. All these results support a possible role of TcNDPK1 in DNA repair mechanisms; however parasites *over expressing the enzyme had an opposite phenotype. We observed a lower growth rate with higher mortality, reaching parasite densities two to three folds lower than control in the stationary phase.* In addition, these parasites had augmented expression levels of activated PARP, an enzyme involved in DNA repair machinery, and twofold increased content of ATP. Such observations are in accordance with the generation of DNA damage, what was observed by gel electrophoresis of the genomic DNA. The non-protective behavior in parasites could be caused possibly by the over expression and deregulation of TcNDPK1. Altogether, these results exhibit the complexity of TcNDPK1 operation and strongly suggest its participation in DNA involving processes, giving rise to novel functions.

Keywords: *Trypanosoma cruzi*, nucleoside diphosphate kinase, DNA repair machinery, mutation

(324) **DEFINING THE FUNCTION OF AN HYPHOTETICAL CALCIUM BINDING PROTEIN IDENTIFIED IN THE PATHOGEN *Trypanosoma cruzi***

María José Ferrer, Diana Patricia Wehrendt, Mariana Potenza

Instituto de Investigaciones en Ingeniería Genética y Biología Molecular ?Dr. Héctor N. Torres?.

Trypanosoma cruzi is the causative of Chagas disease, a neglected illness affecting ~6 million people in Latin America. Calcium and proteins that binds Ca+2 are important for parasite differentiation and infection into mammalian cells. Several channels and proteins that bind Ca+2 are expressed in *T. cruzi*, but most of them remain uncharacterized. We selected a new, hypothetical Ca+2 binding protein (*Tc*CAL1) from *T. cruzi* proteome to study its role in the parasite physiology. *Tc*CAL1 is a 103 amino acid protein containing two EF-hand motifs and it is expressed in all life cycle forms of *T. cruzi*. To define its function, a yeast two-hybrid assay, using a cDNA library from *T. cruzi* has been employed to analyze the association of *Tc*CAL1 with other proteins. We identified two proteins that interact with *Tc*CAL1. One was a protein containing an Armadillo-like domain. The Arm domains are present in several proteins and some of them depends their function on Ca+2 levels or small Ca+2 binding proteins (like S-100 proteins). The other was a hypothetical protein with homology to a prefoldin-like subunit. These proteins form multimeric complex that collaborate with chaperons. In certain complexes, the presence of Ca+2 is essential for an adequate protein folding. As a result, we hypothesize that *Tc*CAL1 can modulate the function of these proteins in different processes. Current work concerns the validation of *Tc*CAL1 associations in co-immunoprecipitation assays from *T. cruzi* extracts. Future work involves studies of *Tc*CAL1 deregulation and their effect on differentiation and infection, in order to establish its role in these processes.

Keywords: Ca+2 binding protein, *Trypanosoma cruzi*

(393) **CHARACTERIZATION OF *Trypanosoma cruzi* ALPHA-TUBULIN ACETYLTRANSFERASE**

Mara Emilia Carloni (1), Victoria Lucia Alonso (1, 2), Luis Emilio Tavernelli (2), Alejandro Pezza (2), Pamela Cribb (1, 2), Esteban Serra (1, 2)

Facultad de Ciencias Bioquimicas y Farmacéuticas, Universidad Nacional de Rosario. (2) Instituto de Biología Molecular y Celular de Rosario (IBR-CONICET).

Among the numerous isoforms of α-tubulin found in the different microtubular structures of *Trypanosoma cruzi*, acetylated α-tubulin is one of the most abundant. In other organisms, one of the enzymes responsible for this modification is the α-tubulin acetyltransferase, or αTAT.

We have identified a coding sequence for the putative αTAT in the genome of *T. cruzi*, established lines that overexpress the protein of interest in an inducible manner, using the pTcINDEX-GW vector and characterized the mutant parasites phenotypically. As a first approach, we evaluated the overexpression of the αTAT in the mutants by western blot analysis (using anti-α-tubulin and anti-acetylated α-tubulin as primary antibodies), showing an increase in the levels of tubulin acetylation when αTAT is overexpressed. Besides, other experiments indicated that the protein localizes mainly in the cytoskeleton and flagellum of *T. cruzi*. Subsequently, we studied the growth of the mutant epimastigotes and a remarkable reduction was observed as a result of an increased expression of αTAT. Furthermore, we studied the morphology of the mutants by phase contrast microscopy and immunofluorescence analysis. The overexpression of αTAT led to an abnormal morphology in the parasites; aberrant nuclei and parasites containing more than one flagellum were observed. In addition, a higher concentration of the protein was detected mainly in the perinuclear region. Finally, we evaluated the phenotypic effect generated by orizalyn, a microtubule depolymerizing drug. Wild-type parasites lose their normal morphology after the treatment in a dose-dependent manner but differences in drug resistance were observed in the overexpressing parasites upon the induction.

These findings suggest that the mechanisms of tubulin modification –particularly acetylation- could influence the functional role of the microtubules, both in cell division and differentiation during the parasite's life-cycle.

Keywords: *Trypanosoma cruzi*, alpha-tubulin, acetylation, cytoskeleton

(1455) **CHARACTERIZATION OF HISTONE DEACETYLASE ENZYMES OF CESTODE PARASITES AS POTENTIAL DRUG TARGETS OF NEGLECTED DISEASES**

Hugo Rolando Vaca, Federico Camicia, Marcela Cucher, Laura Kamenetzky, Natalia Macchiaroli, Ana María Celentano, Mara Cecilia Rosenzvit

Instituto de Investigaciones en Microbiología y Parasitología Médica, IMPAM-UBA CONICET, Facultad de Medicina, UBA, Buenos Aires, Argentina.

Cestode parasites cause neglected diseases such as hydatidosis. These parasites have complex life cycles undergoing metamorphic events that comprise cell proliferation, differentiation and death. This suggests the involvement of a complex system of gene expression control that has been associated with changes in chromatin struc-

ture in trematode parasites. Histone deacetylase enzymes (HDAC) remove acetyl groups from histones and other cellular effectors, thus directly influencing the chromatin structure and thereby regulating gene transcription and other cellular processes. HDAC have been validated as drug targets for the treatment of cancer and other diseases including parasitic infections. However, knowledge of HDAC in cestode parasites is lacking. Previously, we have shown the presence and transcription of HDAC genes in several species of cestode parasites. In this work, we aimed to study the effect of the pan-HDAC inhibitor Trichostatin A (TSA) in *Mesocestoides corti*, a cestode laboratory model. We found a decrease in the viability, measured by AlamarBlue assay and motility index determination, and observed phenotypic alterations in *M. corti* larvae upon incubation with TSA. To assess the molecular target of TSA, we evaluated changes in the total amount of acetylated histone H4 by western blot using anti-acetylated histone H4 antibody. We observed a band corresponding to acetylated H4 histone in parasites treated with TSA but not in control parasites, suggesting that TSA strongly inhibits H4 histone deacetylation. This effect was not observed in parasites treated with praziquantel and albendazole suggesting a specific effect of TSA. These findings suggest that HDAC could have an essential role in cestode development and survival. This work provides a first step into the study of epigenetic mechanisms in cestode parasites and explores new alternatives to treat the diseases they cause.

Keywords: HDAC, neglected diseases, drug targets, cestode parasites.

(1055) **VIRTUAL SCREENING OF FLAVONOIDS AS POSSIBLE INHIBITORS OF *TRYPANOSOMA CRUZI* ARGININE KINASE.**

Edward Valera-Vera, Chantal Reigada, Melisa Saye, Mariana Miranda, Claudio Pereira
Universidad de Buenos Aires, Facultad de Medicina, Instituto de Investigaciones Médicas A. Lanari, Buenos Aires, Argentina; Consejo Nacional de Investigaciones Científicas y Técnicas, Universidad de Buenos Aires, Instituto de Investigaciones Médicas (IDIM), Laboratorio de Parasitología Molecular, Buenos Aires, Argentina.

Arginine kinase from *Trypanosoma cruzi* (*Tc*AK) is an enzyme involved in the energetic homeostasis and response to stressors in the parasite. The activity of enzyme, among some of its homologues from diverse phyla, is inhibited by some flavonoid compounds. In addition to it, one of these inhibitors, the resveratrol, affected the replication and survival of cultured epimastigotes as well as amastigotes/trypomastigotes infecting mammal cell cultures. In order to test other molecules that can throw light on the mode of interaction between the enzyme and the flavonoids, we arranged a simple pipeline that narrows the focus of the testing efforts to a handful of compounds.

For this, we downloaded the (now unavailable) database of medically active plant substances (MAPS), specifically the subset of flavonoid molecules, that comprised 326 compounds, and modeled the molecular interactions between these flavonoids and a homology model of *Tc*AK obtained from the iTASSER online server. These models were carried on two different molecular docking softwares, the open source AutoDock Vina, and the private licensed OpenEye.

Results from each software were ordered according to its docking score, and then both lists were compared to take only the molecules that were present between the best 100 scores of both programs, from which only 5 where shared among the first 20, 7 among the first 50 and 29 among e first 100. From these molecules, only 7 are purchasable, and three of them (delphinidine, malvidine and petunidine) were also present as possibly active compounds in the previous virtual screening that pointed out resveratrol as an inhibitor of the *Tc*AK activity, making them of high interest for future *in-vitro* tests.

Keywords: virtual screening, flavonoids, Arginine kinase, molecular docking

(1068) **DETECTION OF SPECIFIC IGE ANTIBODIES AGAINST *Trypanosoma cruzi* ARGININE KINASE.**

Edward Valera-Vera (1), Karina Gomez (2), Chantal Reigada (1), Melisa Saye (1), Fabio Digirolamo (1), Mariana Miranda (1), Claudio Pereira (1)
(1) Universidad de Buenos Aires, Facultad de Medicina, Instituto de Investigaciones Médicas A. Lanari, Buenos Aires, Argentina; Consejo Nacional de Investigaciones Científicas y Técnicas, Universidad de Buenos Aires, Instituto de Investigaciones Médicas (IDIM), Laboratorio de Parasitología Molecular, Buenos Aires, Argentina, (2) INGEBI-CONICET.

The Arginine Kinase from *Trypanosoma cruzi* (*Tc*AK) is thought to be the product of gene transfer from an invertebrate host to a *Trypanosoma* ancestor. The function of this enzyme in the parasite is still unknown, but since it was found in extra-cellular *T. cruzi* vesicles, and it shares a very conserved sequence with invertebrate AKs, which are well known allergens in a very wide range of species, we suspect that *Tc*AK might have some immune modulating action by making immune response incline towards a Th2 response that is ineffective against the parasite, instead of a Th1 response that could control the infection.

To start testing this hypothesis we decided to measure the presence of *Tc*AK specific IgE antibodies in the serum of individuals infected and non-infected with the parasite. Samples were taken from individuals in Venezuela (49 Chagas positive and 46 Chagas negative) and in Argentina (20 positive and 10 negative), in order to take into account the regional differences in parasite strains and in host immune response. Detection was carried on by ELISA against recombinant *Tc*AK, using secondary anti-human IgE coupled with alkaline phosphatase and pNPP dephosphorilation. Results for each regional sera origin were obtained and treated separately, using for both groups a ROC curve and Mann-Withney test.

With both regional origins of the sera we found statistical significant differences in the *Tc*AK recognition between the non-infected and infected sera, with an Area Under the ROC curve >0,75 and a $p < 0,005$ for both the ROC analysis and the Mann-Withney test. These results points out that infection with the parasite trigers the production of IgE antibodies against *Tc*AK, but wether this priming of the response towards IgE secretion is relevant for the infection is still to be determined.

(311) ***Chlamydia muridarum*** **INDUCE THE EXPRESSION OF CO-INHIBITORY MOLECULES ON IMMUNE CELLS**

Carolina Olivera, Gloria Janet Godoy, Florencia Celeste Salazar, Daniela Andrea Paira, Rubén Darío Motrich, Virginia Elena Rivero
CIBICI-CONICET

Chlamydia trachomatis is the most commonly reported agent of sexually transmitted bacterial infections worldwide. This pathogen frequently leads to long-term persistent subclinical infections, both in male and female. This is in part due to certain mechanisms, not yet fully elucidated, that suppress the immune response to the pathogen. Recently, the role of co-inhibitory pathways in some chronic infections has been studied, and reports suggested that the overexpression of co-inhibitory molecules would be related to pathogen persistence. In the present work we aimed to evaluate the expression profile of co-inhibitory molecules using an *"in vitro"* model with *Chlamydia muridarum* (Cm) stimulation. For that purpose, splenocytes from C57BL/6 and NOD mice were in vitro stimulated for 24-48 h with inactivated Chlamydia Elementary Bodies at different bacteria/cell ratios. After that, PD-L1 and PD1 expression was determined by flow citometry in different cell subpopulations. A significant and dose dependent increase in the percentage of $PD\text{-}L1^+CD20^+$ lymphocytes was found after Cm stimulation when compared with non-stimulated cells ($P < 0.01$). Not only major percentages but also higher mean fluorescence intensity for PD-L1 were observed in B lymphocytes. Cm stimulation also induced higher percentages of $CD4^+PD\text{-}L1^+$ and $CD8^+PD\text{-}L1^+$ T lymphocytes, although in minor proportions when compared with B lymphocytes. Non-significant changes were observed in $CD11b^+PD\text{-}L1+$ and $CD11c^+PD\text{-}L1+$ cell populations. The expression of PD1 showed a similar pattern to

those observed for PD-L1. Moreover, although B and T lymphocytes from C57BL/6 and NOD mice showed PD-L1 overexpression, the NOD strain showed a more pronounced response after Cm stimulation. Our results demonstrate that Chlamydia is able to induce the expression of co-inhibitory molecules mainly in B lymphocytes, possibly attenuating the immune response and favoring chronic and persistence infections in genital tract.

(548) **REGULATORY T CELLS DYSFUNCTION IN INDIVIDUALS WITH TRISOMY 21**

Paula Araya (1), Emiliano Roselli (1), Nicolas G Nuñez (2), Keith Smith (3), Joaquin M Espinosa (3), Mariana Maccioni (1)

(1) Centro de Investigación de Bioquímica Clínica e Inmunologia - FCQ- UNC, Argentina. (2) Institute Curie. Paris, Francia), Katherine Waugh (Linda Crnic Institute for Down Syndrome, University of Colorado School of Medicine, Aurora, Colorado 80045, USA. (3) Linda Crnic Institute for Down Syndrome, University of Colorado School of Medicine, Aurora, Colorado 80045, USA.

Trisomy 21 (T21) is the most common genetic disorder in human population, occurring in approximately 1 in 700 live births. Individuals with T21 have a unique disease spectrum and a hyperactivated Type I interferon signaling, which could be a result of increased gene dosage of the four IFN receptor subunits encoded on chr21. T21 causes widespread alterations in gene expression across the genome, including, most prominently, consistent activation of the interferon transcriptional response. Based on this and the fact that individuals with T21 are predisposed to develop autoimmune diseases, we decided to dissect Treg functionality in individuals with T21, focusing on the effect that the type I IFN-IFNAR axis could have on its biology. We characterized the circulating Treg cells and T cells subsets in individuals with or without T21 using multicolor Flow Cytometry. Individuals with T21 (n=9) have a significantly alteration in the CD4/CD8 ratio ($p<0,001$), and higher numbers of CD8+ T cells compared with controls (n=14, $p<0,05$). Also, these individuals present more CD8+ T cells that produce effector proteins (IFN-γ $p<0,05$ and GzmB $p<0,05$). When we focused on Treg cells, individuals with T21 have a higher number of CD4+Foxp3+ T cells in peripheral blood ($p<0,05$) but the expression of more than 20 phenotypic markers analyzed were similar to controls. Interestingly, individuals with T21 have an increased frequency of IFNAR1+ Treg cells ($p<0,05$). When an *in vitro* suppression assay was performed, a reduced inhibitory potential of Treg was clearly observed in individuals with T21, whereas the proliferative capacity of the responder T cells was the same than their controls.

We hypothesize that the inappropriate Type I IFN activation could contribute with the alteration in the suppressive function of Treg in individuals with T21, and this could explain the increased risk of leukemia and autoimmune disorders, as well as many developmental abnormalities also observed in interferonopathies.

(643) **EVALUATION OF THE EFFECTS OF SKIN ULTRAVIOLET LIGHT EXPOSURE ON PNEUMOCOCCAL VACCINATION EFFECTIVENESS**

Valeria Campo, Eliana Cela, Adrián Friedrich, Juliana Leoni, Daniel González Maglio

Universidad de Buenos Aires - CONICET. Instituto de Estudios de la Inmunidad Humoral (IDEHU).

Cutaneous exposure to UV radiation (UVr) promotes well-known detrimental effects on health, as skin cancer development and specific immunosuppression. However, the impact of this immunosuppression on human vaccination has been poorly studied.

Previously, we have reported that a single high UV dose (shUVd - 400 mJ/cm^2) promotes skin inflammation and decreases CHS reaction. In contrast, repetitive low UV doses (rlUVd - 4 consecutive days, 20 mJ/cm^2) do not induce inflammation and increase CHS.

The aim of the present work was to study the effect of cutaneous exposure to shUVd and rlUVd on the effectiveness of a non-conjugated pneumococcal vaccine and on B-1 cells expansion.

C57BL/6 mice were intramuscularly immunized with Pneumovax23 (MSD), 24h after irradiation. Non-irradiated vaccinated and non-vaccinated mice were used as controls. Specific antibodies (IgM and IgG) were measured by ELISA at different time-points post-vaccination.

Specific IgM and IgG levels were significantly increased in all vaccinated groups ($p<0.01$), but only IgG levels were significantly decreased in shUVd-exposed mice compared with rlUVd ones ($p<0.05$). No significant differences were observed on the B-1 cells percentage (CD45$^+$, CD3$^-$, CD19$^+$, CD43$^+$) in peritoneal cavity 4 and 24 h after immunization (non-irradiated mice).

Therefore, we decided to apply the vaccine intraperitoneally in mocked-irradiated mice. We observed a non-significant increase of the percentage of B-1 cells 4h after immunization and a significant decrease 24h after ($p<0.01$). Specific IgM and IgG levels were significantly increased in all IP vaccinated groups ($p<0.01$), but there were no significant differences between them.

These results show that UVr is able to modulate immune responses to pneumococcal vaccine, promoting a detrimental effect on the humoral response of shUVd exposed-mice. Further studies should be done to elucidate the effects of UVr in the modulation of B-1 cell population.

Keywords: UV, immunosuppression, vaccine, B-1 cells

(821) **DENDRITIC CELLS PLAY A CENTRAL ROLE IN THE PATHOGENESIS OF *Yersinia enterocolitica*-INDUCED REACTIVE ARTHRITIS IN TNFRp55 DEFICIENT MICE**

Andrea Constanza Mayordomo (1), Juan Eduardo Silva (1), Carolina Virginia Gorlino (1), José Luis Arias (1), Walter Berón (2), María Silvia Di Genaro (1)

(1) División de Inmunología, Facultad de Química, Bioquímica y Farmacia, Universidad Nacional de San Luis e Instituto Multidisciplinario de Investigaciones Biológicas (IMIBIO), CONICET, San Luis, Argentina, (2) Instituto de Histología y Embriología, Facultad de Ciencias Médicas, Universidad Nacional de Cuyo - CONICET, Mendoza, Argentina.

Dendritic cells (DC) orchestrate immune responses presenting antigens to T lymphocytes and driving their activation and differentiation to effector T cells. In previous studies, we demonstrated that TNFRp55-deficient (*TNFRp55*$^{-/-}$) mice develop reactive arthritis (ReA) after orogastric infection with *Yersinia enterocolitica* (Ye). The purpose of the present work was to study the contribution of DC in the pathogenesis of Ye-induced ReA in this mouse model. The DC were purified after their *in vivo* expansion by injection of Fms-like tyrosine kinase 3-Ligand (Flt3L)-transfected BL16 melanoma. Isolated WT and *TNFRp55*$^{-/-}$ DC were stimulated with lipopolysaccharide (LPS), and IL-12/23p40 levels were assessed in culture supernatants by ELISA. Moreover, these cells were *in vitro* infected with Ye, and then co-cultured with purified CD4$^+$ T cells obtained from spleen of WT and *TNFRp55*$^{-/-}$ mice 5 days post-infection with Ye. After 5 days, T cell differentiation to Th1 and Th17 profiles were analyzed by flow cytometry, and IFN-γ and IL-17 levels were measured in culture supernatants. We found that *TNFRp55*$^{-/-}$ DC secreted higher levels of IL-12/23p40 compared with WT DCs (*p<0.05*). In co-culture of *TNFRp55*$^{-/-}$ DC with WT CD4$^+$ T cells, we found a significant higher frequency of IFN-γ$^+$CD4$^+$T cells and IL-17$^+$CD4$^+$ T cells (*p<0.05* compared with WT DCs). Accordingly, higher levels of IFN-γ and IL-17 were detected in these culture supernatants (*p<0.001* compared with WT DC). These findings indicate that DC play a critical role in the pathogenesis of Ye-induced ReA in *TNFRp55*$^{-/-}$ mice by overproduction of IL-12/23p40, and consequently driving Th1 and Th17 programs. The results suggest the existence of a TNFRp55-mediated anti-inflammatory circuit in DC. Therefore, these cells may be considered as a novel target in the treatment of ReA.

Keywords: dendritic cells, reactive arthritis, TNFRp55, *Yersinia enterocolitica*

(1004) **DEVELOPMENT AND VALIDATION OF A RECOMBINANT PROTEIN BASED COMPETITIVE-INHIBITION**

ELISA FOR DETECTION OF NEOSPOROSIS IN CATTLE

Maria Belen Novoa (1, 2), Beatriz Valentini (1), Macarena Sarli (1), Maria Evangelina Primo (1, 2), Ignacio Echaide (1)
(1) Instituto Nacional de Tecnología Agropecuaria, Estación Experimental Agropecuaria Rafaela, (2) Consejo Nacional de Investigaciones Científicas y Técnicas.

Infection with *Neospora caninum*, an apicomplexan protozoan parasite, causes significant economic losses in cattle worldwide due to abortions. The reference method for serodiagnosis of neosporosis is the indirect fluorescent antibody test (IFAT), in spite of its complexity and subjectivity. The aim of this study was to develop and validate a competitive-inhibition ELISA (cELISA) based on major surface antigen protein (SAG1) of *N. caninum* and the monoclonal antibody (mAb) P1C2D8F8, for detection of antibodies to *N. caninum* in cattle. A truncated variant of NcSAG1 was expressed as a recombinant protein (rSAG1) in *Escherichia coli.* The mAb was generated by immunizing mice with sonicated *N. caninum* tachyzoites. $cELISA_{rSAG1}$ was standardized under different physicochemical conditions. Sera (n=1085) from 264 dairy cows, with known status of neosporosis infection were used as gold standard. Infected and uninfected population were defined as those with at least three consecutive positive (n=385) or negative (n=700) results by IFAT and $cELISA_{tach}$ (in-house test based on lysed tachyzoites), over four years monitoring. The prevalence of neosporosis in 262 beef cows from 12 herds of Santa Fe province was evaluated using the $cELISA_{rSAG1}$, and the results compared with IFAT, $cELISA_{tach}$ and commercial $cELISA_{VMRD}$. The efficiency of the $cELISA_{rSAG1}$ and agreement (*kappa*) with other tests was evaluated by Receiver Operating Characteristic analysis. The rSAG1protein had high yield, solubility and stability. $cELISA_{rSAG1}$ showed 97.1% sensitivity and 97.6% specificity with a cutoff point of 28% of inhibition. The prevalence of neosporosis in beef cattle was 36%. The agreement between $cELISA_{rSAG1}$ and IFAT or $cELISA_{tach}$ or $cELISA_{VMRD}$ was 92% *(k*= 0,820); 95% (*k*= 0.880); and 96% (*k*= 0.905*)* respectively. The $cELISA_{rSAG1}$ is simple, fast, and could be used for large-scale epidemiological studies or disease-monitoring programs of multiple animal species.

(1096) **EFFECT OF CIRCADIAN VARIATIONS IN MUCOSAL IMMUNE RESPONSE TO FOOD ANTIGEN**

Bibiana Elisabet Barrios (1), Lisa Macció Maretto (1), Franco Nicolás Nazar (2), Ivanna Novotny Núñez (1), Silvia Graciela Correa (1)
(1) Facultad de Ciencias Químicas, UNC. CIBICI-CONICET, (2) Instituto de Investigaciones Biológicas y Tecnológicas. CCT-CONICET. Córdoba

Many immune parameters oscillate rhythmically with the time of day and the circadian clock has emerged as an important gatekeeper that enhances fitness of the organism. In the present work we have characterized the influence of biological rhythms on the immune function of the intestinal mucosa and its impact on the tolerance towards oral antigens. Using multivariate statistic tests (PCA , ADL, MANOVA), we evaluated 17 parameters (cell subsets, homing receptors, activation markers and cytokines) in mesenteric lymph nodes (MLN) of B6 WT mice exposed to light-dark 12:12 conditions at four times (ZT5, 11, 17 and 23). PCA and ADL tests confirmed that over a 24-hr period, three different immune configurations can be described in MLN: at the light period (ZT 5); at the dark period (ZT17) and at the transition periods (ZT11 and 23). The distribution in these groups was dependent on the integrity of the molecular clock, as mice deficient in the clock gene *Per2* (Per2KO), showed significant differences with WT animals ($p<0.05$) as well as a reduction on the oscillatory pattern. We evaluated if immune configurations observed at ZT5 and ZT17 could be both competent to induce tolerance toward a fed antigen (ovalbumin-OVA). Using two models of tolerance, we found that the intake of the antigen during the late dark phase (ZT23) induced more tolerance evaluated as lower proliferation rates. Moreover, OVA specific T cells ($CD4^+$ $OT\text{-}II^+$) with increased expression of Foxp3 transcription factor ($p<0.05$) and selective localization in the lamina propria was elicited by the daily administration of OVA at the end of the dark phase. Our results demonstrate that in a period of 24 h, the feeding during the dark period and the development of tolerogenic responses seem synchronized in the MLN promoting the tolerance development that is essential for intestinal homeostasis.

(1289) **DISSECTING THE ROLE OF GALECTIN-3, IFN-γ AND MICROBIOTA IN GERMINAL CENTER B CELL FATE DECISIONS.**

Cristian Gabriel Beccaria (1), Facundo Fiocca Vernengo (1), María Carolina Amezcua Vesely (1), Laura Almada (1), Juan Mucci (2), María Cecilia Ramello (1), Jimena Tosello Boari (1), Oscar Campetella (2), Carolina Lucia Montes (1), Eva Virginia Acosta Rodriguez (1), Adriana Gruppi (1)
(1) Centro de Investigaciones en Bioquímica Clínica e Inmunología (CIBICI)-CONICET, Facultad de Ciencias Químicas, Universidad Nacional de Córdoba, X5000HUA, Córdoba, Argentina. (2) Instituto de Investigaciones Biotecnológicas, Universidad Nacional de San Martín, San Martín, Argentina.

Germinal Centers (GC) are unique structures where high affinity antibodies and memory B cells are generated. With the aim of ensure fast selection of rapidly evolving clones in GCs, follicular dendritic cells, GC B cells and T cells engage in multiple interactions. So far, only co-stimulatory or inhibitory membrane immune receptor/ligand pairs and cytokines have been investigated and are known to be involved in this process. However, there is a pressing need to understand other factors that regulate GCs in order to optimize and control humoral responses following vaccination, antibody-mediated autoimmune diseases, and GC B cell-derived malignancies. Here, we report a novel effector function by which Galectin-3 (Gal-3), a β-galactoside binding protein, is critically involved in the development of GCs. Gal-3 KO mice exhibit high frequency of spontaneous GC (sGC) B cells and T follicular helper (Tfh) cells that correlated with hypergammaglobulinemia, high amounts of IFN-γ in serum and lupus-like autoimmune manifestations. We found that the main source of IFN-γ in Gal-3 KO mice were CD4+ T cells (including Tfh), since there are no significant differences between IFN-γ-producing CD8 T, NK, NKT and DCs cells between groups. IFN-γ blockade in Gal-3 KO mice prevents the autoimmune condition, demonstrating that IFN-γ overproduction sustain lupus-like disease. We were also wondering whether specific microbiota in Gal-3 mice could influence the induction of sGCs. Microbiota modulation by antibiotic treatment could not prevent sGCs induction in Gal-3 KO mice and, interestingly, these mice did not modify the generation of GCs in Peyer's patches after treatment, unlike the WT mice which showed a deep reduction of them. Finally, using chimeric mice with B cell-specific deficiency of Gal-3, we reveal that intrinsic Gal-3 signaling in B cells control sGC formation. Together, our data provide the first evidence that Gal-3 acts directly on B cells regulating GCs responses via IFN-γ.

(1598) **EFFECT OF *Trypanosoma cruzi* CYTOSOLIC TRIPAREDOXIN PEROXIDASE ON PERIPHERAL BLOOD MONONUCLEAR CELLS FROM PATIENTS WITH CHRONIC CHAGAS DISEASE**

Magalí Celeste Girard (1), Gonzalo R Acevedo (1), María D Piñeyro (2), Juan P Grosso (3) Micaela S Ossowski (1), Marisa Fernandez (4), Yolanda Hernandez Vasquez (4), Carlos Robello (2), Karina A Gómez (1)
(1) INGEBI-CONICET. (2) Institut Pasteur Montevideo. (3) IFIBYNE (UBA-CONICET). (4) Instituto Nacional de Parasitología "Dr. Mario Fatala Chabén".

Trypanosoma cruzi, the etiological agent of Chagas disease (ChD), has a highly efficient detoxification system to deal with the oxidative burst imposed by its host. One of the antioxidant enzymes involved is the cytosolic tryparedoxin peroxidase (TcCPx) which catalyzes the reduction of hydrogen peroxide, small-chain organic hydroperoxides and $ONOO^-$. This enzyme is present in all parasite stages, and its over-expression renders parasites more resistant to oxidative defenses of macrophages, indicating an important role in

parasite survival. However, TcCPx not only constitutes a relevant virulence factor in ChD, but also promotes inflammatory reactions in *T. cruzi*-infected mice. The aim of this study was to analyze the specific humoral and cellular immune response triggered by TcCPx in chronic asymptomatic (n=7) and cardiac patients (n=6), and non-infected individuals (n=5). Results showed that levels of IgG antibodies against TcCPx were low (titer<1/400) in sera from individuals across all groups. However, after five days of *in vitro* stimulation, TcCPx induced proliferation of peripheral blood mononuclear cells (PBMC) from asymptomatic patients (p<0.01). In addition, only interferon-γ, but not GM-CSF or IL-10, were detected in the supernatant of PBMC from asymptomatic patients (p=0.04) under the same culture conditions. No response of either type was observed in cardiac patients and non-infected individuals. NetMHCpan and NetMHCIIpan were used to predict potential binding peptides within TcCPx for HLA-class I and II, respectively. The algorithm highlighted four regions of 16-23 aminoacids long containing peptides with high binding probability to most prevalent alleles of α and β chains of HLA-II in central and Northern Argentine population, while potential HLA-I epitopes were mostly found in N-terminal region of the protein. We expect that our research can contribute to understand the role of TcCPx on the immune response of chronic Chagas disease patients.

It is known that desmogleins are involved in cell adhesion mechanisms and are crucial in keeping structural integrity of different tissues, including skin. They also play important roles in differentiation, cell activation and migration. Keratinocytes (KC) produce several inflammatory factors that modulate leukocytes. Psoriasis is a chronic inflammatory skin disease, characterized by KC hyperproliferation, vasculature growth, and leukocyte infiltration into the dermis and epidermis. Imiquimod (IMQ) is an immunomodulator used in mice to induce lesions closely resembling human psoriasis. The aim of our work was to assess the impact of desmoglein-4 deficiency in the amount of skin leukocyte infiltration in an IMQ induced psoriasis model in rats. To this end, OFA hr/hr rats, which are mutant for the desmoglein-4 gene and Sprague-Dawley (SD) wild type rats were used. IMQ was administered to both strains in shaved skin for four days to generate psoriasis-like lesions. Skin biopsies from treated and untreated OFA and SD rats were weighed and minced to obtain cell suspensions that were stained with monoclonal antibodies against CD45 (panleukocytary lineage) and CD3 (T cell lineage) conjugated with fluorochromes and analyzed by flow cytometry. Interestingly, we found that IMQ treatment to both groups increased CD45+ CD3+ cells in OFA skin compared to controls, but this difference was much greater and significant in OFA rats (SD 0.79±0.24 vs OFA 4.12±0.75, p<0.05) that correlated with increased inflammatory area and histopathologic changes in OFA rats. These results suggest that desmoglein-4 absence contributes to psoriasis progress, promoting expansion of leukocyte population in skin. Although further research is needed, these results could have a potential impact on the design of clinical therapies for psoriasis progression.

Keywords: Desmoglein-4, psoriasis, imiquimod, immune response

(1894) **DENDRITIC CELLS ARE RESPONSIBLE FOR THE FAILURE IN CTLs GENERATION IN LSP1-DEFICIENT MICE**

Rachel Paola Acland Strack (1), Marine Gros (2), Mercedes Pascual (1), Belkys Maletto (1), María Cristina Pistoresi (1), Ana María Lennon-Dumenil (2), Sebastián Amigorena (2), Gabriel Morón (1)

(1) CIBICI CONICET, Departamento de Bioquímica Clínica, Facultad de Ciencias Químicas, Universidad Nacional de Córdoba, Córdoba, Argentina. (2) INSERM U932, PSL Research University, Institut Curie, Paris, France.

Leukocyte-specific protein 1 (LSP1) is an important regulator of actin cytoskeleton remodeling, modulating leukocytes motility, due to its F-actin binding domain. We have previously shown that *Lsp1*$^{-/-}$ mice have an impaired CTL response after antigen exposure. Moreover, *Lsp1*$^{-/-}$ dendritic cells (DCs) fail to induce a strong CTL response in vivo, migrate to lymphoid tissues, present antigens and produce IL-12 when transferred into WT mice.

In order to deepen the mechanisms operating this diminished CTL generation in *Lsp1*$^{-/-}$ mice, we first analyzed the ability of their CD8$^+$ T cells to proliferate and become activated. After *in vitro* stimulation with αCD3/CD28, *Lsp1*$^{-/-}$ CD8$^+$ T cells proliferated and up-regulated CD25 as strongly as WT CD8$^+$ T cells. Granzyme B production and IFNγ release were slightly lower (p<0.05) in *Lsp1*$^{-/-}$ vs WT CD8$^+$ T cells, with no difference in IFNγ production.

Then, we evaluated *in vitro* activation of CD8$^+$ T cells purified from OT I (*Lsp1*$^{+/+}$) mice after culture with BMDCs (differentiated from bone marrow precursors with Flt3-L), previously pulsed with latex beads coated with ovalbumin, plus CpG-ODN. Cell proliferation, CD25 up-regulation and IFNγ secretion was significantly lower in T cells cultured with *Lsp1*$^{-/-}$ BMDCs than with WT BMDCs (p<0.01). Finally, we compared the ability of Flt3L-BMDCs from *Lsp1*$^{-/-}$ and *Lsp1*$^{+/+}$ mice to translocate antigen from endosomes to cytosol by performing the βLactamase export assay. *Lsp1*$^{-/-}$ BMDCs showed a slower escape of βLactamase to the cytosol, indicating a slower Ag translocation than in WT BMDCs.

In conclusion, these results reveal that the diminished generation of CTLs we observed in *Lsp1*$^{-/-}$ mice is due to a deficiency in the ability of DCs to cross-present Ag rather than a failure in their CD8$^+$ T cells. This deficiency in *Lsp1*$^{-/-}$DCs is related to an alteration in the escape of the antigen from endosomes to the cytosol, which led to fewer antigens associated to MHC-I to be presented to CD8$^+$T cells.

Keywords: LSP1; Dendritic Cells; Cross-presentation; CTLs.

(182) **THE TSf-ISPA FORMULATION CONFERS PROTECTIVE CAPACITY AGAINST *Trypanosoma cruzi* INFECTION AFFECTING CELLULAR POPULATIONS WITH REGULATORY/SUPPRESSOR PHENOTYPE**

Carolina Roldán (1), Estefanía Prochetto (1), Daiana Bertona (1), Iván Bontempi (2), Miguel, H. Vicco (1), Luz, M. Rodeles (1), Lihue, N. Gonzalez (1), Giuliana Lupi (1), Iván, M. Marcipar (2), Gabriel Cabrera (2)

(1) Laboratorio de Tecnología, FBCB, UNL. (2) Laboratorio de Tecnología, FBCB, UNL, Facultad de Cs. Médicas, UNL

Introduction: Previously, we have described that a fragment of the trans-sialidase protein (TSf) formulated with an adjuvant developed by our group (ISPA) conferred protective capacity against *Trypanosoma cruzi* (*T. cruzi*) infection.

Objective: to advance in the characterization of the regulatory immune response generated after TSf-ISPA immunization as well as after immunization and *T. cruzi* infection.

Material and methods: BALB/c mice were immunized 3 times every 15 days with 10ug TSf plus 5ug ISPA (TSf-ISPA group) (PBS was used as a control). Fifteen days after the last immunization, mice were challenged with 1000 trypomastigotes (Tulahuen). 7 days after immunization and 14 and 21 days post infection (p.i), flow cytometry was carried out to measure the percentage and number of spleen CD4+ Foxp3+ (Treg) cells and CD11b+GR-1+ myeloid-derived suppressor cells (MDSC).

Results: After immunization, the TSf-ISPA group showed similar levels of Treg cells and a slight but significant increase in the percentage and absolute number of MDSC cells in the spleen. (mean% CD11b+GR1+ ±SD): TSf-ISPA: 5.3±1.7; PBS: 3.2±0.5, p<0.05, n=4 per group.

At 21 days p.i. an increase in the number of Treg cells in the spleen of the immunized and infected mice (TSf-ISPA Tc+) was registered

as compared to the PBS infected group (PBS Tc+). In addition, a decrease in the percentage and absolute number of MDSC cells in the TSf-ISPA Tc+ group was observed as compared to PBS Tc+. Example: (mean% CD11b+GR-1+ ±SD) TSf-ISPA Tc+: 9.5±1.3; PBS Tc+: 17.1±2.1, p<0.05, n=4 per group). In addition, the results showed that the TSf-ISPA formulation affected significantly (p<0,05) the granulocitic-MDSC subtype (CD11b+Ly6G+LY6C+/-) and not influenced significantly (p>0,05) the monocitic-MDSC subtype (CD-11b+Ly6C+Ly6G-).

Conclusion: these results show that the protection conferred by TSf-ISPA immunization correlates with alterations in cellular populations with regulatory/suppressor phenotype.

(195) **EVALUATION OF PEPTIDE FORMULATIONS AND ADJUVANT DOSES REQUIRED TO ELICIT A SPECIFIC CD8+ T CELL RESPONSE AGAINST AN ENDOGENOUS PROSTATE CANCER OVER-EXPRESSED ANTIGEN**

Gustavo Ezequiel Carrizo, Enrique Sebastian Corapi, Daniel Georges Compagno, Diego José Laderach

Laboratorio de Glico-oncologia molecular y funcional; Departamento de Quimica Biologica, IQUIBICEN-CONICET, Facultad de Ciencias Exactas y Naturales-UBA

Active immunization has been proposed as a promising strategy for treatment of advanced Prostate Cancer. However, few tumor associated antigens have demonstrated to elicit an efficient immune response and moreover, our knowledge about how to perform such immunizations remains incipient. Previously, we postulated Galectin-1 as a novel immunogen in PCa and immunizations with a Gal-1 derived peptide induced specific cytotoxicity. This work evaluates different conditions to ameliorate the immunization protocol. First, we decided to comparatively study the use of short peptides (Gal-1 MHC class I and PADRE MHC Class II) *vs* a long peptide (both peptides joined by a cleavable link). Second, we evaluated the adjuvancy doses. Both peptide formulations combined with conventionally used doses of adjuvants (900mM PolyU + 25uM CpG) do not induced specific cytotoxicity while 1/32 lower adjuvant doses induced 15% for the long peptide *vs* 2% for the short ones (p <0.05, t-test) at day 7 post-priming. This prompted us to comparatively characterize at the cellular level these different immunization protocols. Immunization with long peptide and lower doses of adjuvant demonstrated a moderate total lymph node cell burst in contrast to the great expansion seen with conventional doses of adjuvant. Additionally, lower doses of adjuvant decreased Tregs and more importantly, induced a 2.8 fold increase in the absolute numbers of tetramer specific CD8+ T cells. These parameters could explain the higher response obtained. To gain better insights about parameters required for an optimal boost, we demonstrated that low levels of adjuvant are required in re-stimulations but, in this phase, long peptides do not increase the specific cytotoxicity while the short ones do, suggesting that the use of long peptides is only crucial at priming. In summary, our results challenge current ideas about the parameters required to perform a better immunization against an endogenous, tumor-overexpressed antigen.

Key words: cancer immunotherapy, novel therapeutic targets, specific CD8+ T cells

(256) **ASSESSMENT OF BENZNIDAZOLE AND CCR4 ANTAGONIST COMBINATION FOR *Trypanosoma cruzi* CHRONIC INFECTION TREATMENT**

Benznidazole (Bz) is the main drug used to treat *T. cruzi* infection. Besides its parasiticide effect it is able to stimulate T cell specific effector responses. Taking in mind that this immunological modulation has shown to be important for parasite eradication, in this work we hypothesized that the efficacy of Bz treatment could be improved by inhibiting T regulatory cells, using a CCR4 antagonist receptor (CCR4a). BALB/c mice were infected with 10^6 trypomastigotes of Sylvio *T. cruzi* strain. Treatment was administered at 120 days post infection (dpi) and groups were assigned as follow: CCR4a+Bz (treated with subcutaneous CCR4a and oral administration of Bz 100 mg/kg); CCR4a alone; Bz alone (100 mg/kg); PBS (untreated infected group) and NI (non-infected group). At 188 and 273 dpi, parasitemia was evaluated by qualitative PCR. Also, specific IgG1 and IgG2a levels were measured by indirect ELISA. At 273 dpi, electrocardiograms (ECG) were carried out and heart parasite load was determined by PCR real time. In all infected groups, the presence of the parasite was found before and after different treatments. Heart parasite load at day 273 was not significantly different in all infected groups. Levels of specific antibodies were meaningfully increased in all groups after treatment (p <0.05), being IgG2a levels higher than IgG1 levels in all cases (p <0.05). IgG2a levels decreased in CCR4a+Bz in relation to the PBS group (p <0.05). NI mice did not present electrical disturbances in ECG. In the same way, CCR4a+Bz group demonstrated a trend to a lower frecuency of arrhythmias comparing to PBS (p = 0.059). Otherwise, groups with CCR4a and Bz alone did not decrease these alterations. Our results suggest a possible synergy of both drugs although it would be necessary to enlarge the groups to corroborate these findings.

(791) **ALLOGENEIC AND SYNGENEIC CELLS AS ANTIGEN SOURCE AND THEIR EFFICIENCY IN DC-BASED ANTI-MELANOMA VACCINATION**

Sofía Bentivegna (1), Soledad Mac Keon (1), Estrella M. Levy (2), Michael S. Marks (3), Adriana R. Mantegazza (3), Rosa Wainstok (1, 4, 5), José Mordoh (1, 2. 6)

(1) Laboratorio de Cancerología, Fundación Instituto Leloir- IIBBA-CONICET, Buenos Aires, Argentina, (2) Centro de Investigaciones Oncológicas-Fundación Cáncer, Buenos Aires, Argentina, (3) Dept. of Pathology & Laboratory Medicine, Childrens Hospital of Philadelphia, Philadelphia, USA, (4) Laboratorio de Biología Tumoral, IQUIBICEN-CONICET-UBA, Buenos Aires, Argentina, (5) Laboratorio de Biología Tumoral, Dept. de Química Biológica, FCEN, UBA, Buenos Aires, Argentina, (6) Instituto Alexander Fleming, Buenos Aires, Argentina.

A major obstacle to obtaining relevant results in cancer vaccination has been the identification of immunogenic antigens. In particular, dendritic cell (DC)-based cancer immunotherapy can be achieved by loading DCs with syngeneic or allogeneic cells, but the consequences brought upon anti-tumor protection are not clear. When using syngeneic tumor cells, tumor self-antigens, including cancer testis antigens (CTA), other tumor-associated antigens (TAA) and neoantigens generated through mutations during tumor progression, are provided. On the other hand, allogeneic tumor cells could only supply shared CTA and other TAA. To assess the advantages of each system, we have analyzed in a murine model the effect on anti-melanoma protection of loading DCs with irradiated syngeneic B16-F1 melanoma, allogeneic Cloudman melanoma, or allogeneic 4T1 mammary carcinoma cells (DC-ApoNec vaccines). The cells were fully characterized by whole Exome Sequencing and RNAseq. Using Spinning Disk Confocal Microscopy we observed that irradiated tumor cell components were efficiently internalized by DCs, and transported to MHC-class II-positive tubulovesicular compartments. Loading DCs with allogeneic cells induced significantly higher DC maturation than syngeneic cells, measured by Flow Cytometry as CD86 and I-A^b surface expression. DC-ApoNec vaccines were administered to C57Bl6 mice, followed by B16-F1 tumoral challenge. Allogeneic melanoma cells induced effective anti-melanoma protection (p<0.05), but syngeneic melanoma cells established a more potent (p<0.001) and long-lasting protection. Interestingly, when allogeneic mammary carcinoma cells were used to load DCs, short-

term (p<0.001) and long-lasting anti-melanoma protection were also obtained. By RNAseq, we determined that B16-F1 neoantigens were not present in allogeneic cells, while shared CTA and other TAA and were identified in syngeneic and allogeneic cells, suggesting they play an important role on efficient anti-tumor protection.

Keywords: anti-melanoma vaccination, dendritic cells, allogeneic cells, syngeneic cells.

(891) **CO-ADMINISTRATION OF *Toxoplasma gondii* SERINE-PROTEASE INHIBITOR-1 WITH ALLERGEN INDUCES REGULATORY CELLS IN ASTHMATIC MICE**

Ariadna Soto, Ignacio Fenoy, Vanesa Sánchez, María de los Angeles Aldiríco, Matías Perrone Sibilia, Mariano PIcchio, Nadia Arcon, Florencia Giorgio, Valentina Martín, Alejandra Goldman
UNSAM, ECyT, CESyMA

By using a therapeutic experimental asthma model we previously showed that treatment with *T. gondii* serine protease inhibitor-1 (TgPI-1) significantly reduced airway hyper-responsiveness and inflammation. Moreover, co-administration of TgPI-1 with the allergen showed an enhanced improvement compared with the administration of TgPI-1 alone. Besides, we observed that allergen-specific Th1 and Th2 responses were diminished. Based on these results, in the present study we sought to explore whether regulatory cells may account for the effect of TgPI-1. For this purpose we first evaluated if TgPI-1 treatment modulates allergen-specific T cell proliferation. BALB/c mice ip. sensitized with ovalbumin (OVA)/Alum and aerosol challenged, were intranasally treated with TgPI-1 (PI) or TgPI-1+OVA (OPI). Controls included non-sensitized mice (N), and asthmatic mice treated with PBS (O) or with OVA (OO). One week after the treatment, mice were re-challenged. Only mice treated with OPI showed a significant reduction in thoracic lymph node cells OVA-specific proliferation (OPI vs OO; p<0.001). This treatment also induced a significant increase in $CD4^+Foxp3^+$ Treg cells compared to *naïve* mice (p<0.05). These results were not accompanied by an increase in TGF-β or IL-10 production. A significant expansion of Tregs (p<0.05) and a diminished allergen specific proliferation (p<0.01) in OPI group compared to OO and N groups was also detected at systemic level. Similar to lymph nodes, PI treatment didn`t result in a higher frequency of $CD4^+Foxp3^+$ cells nor a reduced OVA-specific splenocyte proliferation. These results might explain the better outcome of co-administration of TgPI-1 with allergen and suggest that $CD4^+Foxp3^+$ Treg cells might be involved. Functional studies will be undertaken to confirm this hypothesis. Overall, TgPI-1 emerges as a promising tolerogenic adjuvant to be included in therapeutic vaccine formulations.

Key words: Asthma, Serine-protease inhibitor, Immunotherapy

(959) ***BRUCELLA ABORTUS* U-OMP19 IMPROVES THE IMMUNE RESPONSE AND PROTECTIVE CAPACITY OF ENTEROTOXIGENIC *ESCHERICHIA COLI* (ETEC) ANTIGENS**

Franco Luis Martinez (1), Lorena Mirta Coria (1), Laura Bruno (1), Karina Alejandra Pasquevich (1), Maria Laura Darriba (1), Marianela Verónica Carabajal (1), Tim Vickers (2), James Fleckenstein (2), Juliana Cassataro (1)
(1) Instituto de Investigaciones Biotecnológicas "Dr. Rodolfo A. Ugalde" ' - Instituto Tecnológico de Chascomús (IIB-INTECH). Universidad Nacional de San Martín (UNSAM) CONICET, San Martín, Buenos Aires, Argentina, (2) Department of Medicine, Division of Infectious Diseases and Molecular Microbiology. Washington University School of Medicine, Saint Louis, Missouri, USA

Enterotoxigenic *E. coli* (ETEC) is the most common cause of bacterial diarrhea both among children in developing countries and in travelers to these regions. Both naturally acquired infection and oral-mucosal vaccination against ETEC enterotoxins, colonization factors or adhesins can induce protective immunity. EtpA, an extracellular ETEC adhesin, is a novel antigen (Ag) with immunogenic and protective capacity found recently.

We propose to use a bacterial protease inhibitor, U-Omp19 from *Brucella abortus*, as platform to deliver antigens in oral formulations against infectious diseases since this protein can protect antigens (Ags) from digestion and it can also trigger and direct the type of immune responses. Thus in this work our aim was to investigate the effect of U-Omp19 co-delivery on EtpA immunogenicity and protective efficacy. To this end inbread BALB/c and outbread CD1 mice were orally immunized with i) saline ii) EtpA iii) EtpA+Omp19 iv) EtpA+dmLT or v) EtpA+dmLT+Omp19. Different doses of EtpA were studied alone or plus adjuvants. Fecal and serum anti-EtpA and anti-LT antibodies (Abs) were evaluated by ELISA. Cellular immune responses or the protective capacity of formulations against oral challenge with ETEC H10407 were also evaluated.

Results obtained indicated that U-Omp19 co-delivery increased mucosal anti-EtpA or anti-LT Abs (IgA in fecal extracts) and induced EtpA-specific IgA and IgG producing memory B cells in bone marrows. U-Omp19 improved Ag-specific IFN-γ and IL-17 response in spleens (P<0.05) and mesenteric lymph nodes (P<0.01). Moreover, U-Omp19, when co-delivered with EtpA or with lower doses of dmLT and EtpA induced significant protection (P<0.05) against oral challenge with ETEC H10407, while the Ags alone did not.

All together our results indicate that U-Omp19 can help to reduce Ag dose and could be a good candidate to be included in new vaccine formulations against ETEC.

Keywords: U-Omp19; ETEC; vaccine; adjuvant; EtpA

(1212) **A LIQUID CRYSTAL NANOSTRUCTURE, USED AS VACCINE PLATFORM, MODIFIES BIODISTRIBUTION OF VACCINE COMPONENTS**

In the last years much effort in vaccinology has focused on the new formulation strategies for subunit vaccines. We formulated OVA (antigen) and CpG-ODN (TLR-9 agonist) with a nanostructure formed by self-assembly of 6-O-ascorbyl palmitate (Coa-ASC16). *We have previously shown that* this nanovaccine (OVA/CpG-ODN/Coa-ASC16) elicited an adaptive immune response superior to those induced by an aqueous formulation (OVA/CpG-ODN). However, we still do not know exactly the mechanisms of action of Coa-ASC16. Hence, the aim of this work was to test the impact of this nanoformulation on biodistribution of vaccine components and early immune response. Methods: mice were s.c. immunized with OVA/CpG-ODN or OVA/CpG-ODN/Coa-ASC16. OVA and CpG-ODN were labeled with near-infrared fluorescent dye, and both signals were measured with an Odyssey® CLx at several time points post immunization (pi). Cytokines/chemokines were evaluated in plasma by a multiplex assay at 1.5h pi. Results are indicated as OVA/CpG-ODN vs OVA/CpG-ODN/Coa-ASC16. Liver: OVA signal was 1.2×10^7 vs 0.6×10^7 (p<0.01), 4.3×10^7 vs 1.0×10^7 (p<0.001) and 2.0×10^7 vs 0.8×10^7 (p<0.01) at 20 min, 2 and 4h pi. No signal was observed in spleen and kidney in any of groups. Injection site: OVA signal was 1.6×10^6 vs 6.9×10^6 (p<0.001) and 0.05×10^6 vs 2.45×10^6 (p<0.05) at 0.3 and 5 days pi; for CpG-ODN there was no significant differences between both groups at any time. Lymph node: OVA signal was 1.8×10^5 vs 0.3×10^5 (p<0.01), 0.5×10^5 vs 4.5×10^5 (p<0.001) and 0.1×10^5 vs 2.8×10^5 (p<0.01) at 20 min, 2 and 24h pi; in contrast CpG-ODN signal was similar between two groups at 20 min and 2h pi. In addition, soluble vaccine elicited higher amounts of systemic TNF-α and MCP-1 than nanovaccine immunization (p<0.05). Conclusions: Coa-ASC16 retains antigen at the injection site but not CpG-ODN, and promotes co-delivery of both molecules to lymph node without concomitant induction of systemic inflammation.

Keywords: vaccine, adjuvant, nanostructure, CpG-ODN

(1848) **EFFECTS OF EDIBLE MUSHROOMS EXTRACTS ON PLATELET ACTIVATION AND AGGREGATION**

María Eugenia Díaz (1,2), Gabriela Fernanda Rocha (2), Sebastian Kravetz (3), Adonis Giorgi (3), Mauricio De Marzi (1,2)
(1) CONICET. (2) Departamento de Ciencias Básicas, Universidad Nacional de Luján. (3) INEDES-CONICET-UNLu.

Mushrooms have been used as food and medicine in different cultures. Beside their high nutritional value, mushrooms are rich in many bioactive compounds of high medicinal values such as small organic molecules, polysaccharides and proteins. These bioactive components have become popular sources of natural antitumor, antiviral, antimicrobial and immunomodulatory agents. In particular, immunomodulators have gained much interest because of the increasing growth of the immunotherapy sector. The immunomodulators are substances which can stimulate, suppress or modulate any of the components of the immune system, including platelets. Although they are known mainly for maintaining vascular integrity, platelets are potent modulators and effectors of inflammatory and immune processes.

Taking into account mushroom properties and the role of the platelets in the immune response, the aim of this work was to study the effect of different extracts on platelet aggregation and activation. In order to achieve this goal, protein enriched extracts of *Agaricus bisporus* (Champignon and Portobello), *Ganoderma lucidum* (Reishi) and *Lentinula edodes* (Shiitake) were prepared, and platelets were exposed to them for one hour. After that, an aggregation assay using thrombin as an agonist was performed. In addition, secretion of different cytokines was analyzed by ELISA.

The results showed that Champignon, Reishi and Shiitake extracts modified platelet aggregation kinetics. On the other hand, Portobello extract was able to reduce platelet aggregation. Regarding cytokines secretion, none of the extracts increased IL-6 expression, but *Agaricus bisporus* extracts (Champignon and Portobello) were able to induce INFγ secretion.

In conclusion, these findings suggest that extracts of the edible mushrooms studied have compounds that could be used as modulators of platelet activation. Thus, the extracts obtained are a promising source of immunomodulatory compounds.

Keywords: edible mushrooms, immunomodulators, platelet activation

Apis mellifera L. is an essential pollinator affected by several stressors linked with colony losses and the disturbance of their ecological function. Among this, *Varroa destructor,* an ectoparasitic mite affects seriously the colonies. The relationship between stressors and bee symbionts is being studied to enhance bee health. The goal of this study was to evaluate the effect of cell-free supernatants (CFS) produced by *Lactobacillus johnsonii* AJ5*,* a bee bacterial symbiont, on *A. mellifera* nutrition, immunity and their toxicity against *V. destructor.* Bees in cages were fed *ad libitum* with a solution of 40% v/v (CFS/sugar syrup) for 6 days. Two controls were performed: one with sugar syrup (50% w/v) and the other with a solution of MRS broth and syrup (6.25 % v/v). Assays were performed by triplicate. Soluble protein was assessed in samples of 20 abdomens per treatment. Samples of each replicate were used to analyze by quantitative real-time PCR (qRT-PCR) the expression of immunity genes: Vitellogenin (Vg), Insulin-like peptides 2 (Ilp2), Domeless (Dom), Hymenoptesin (Hym) and Propheniloxidase (Ppo), using beta actin as housekeeping gene. Toxicity against *V. destructor* was assayed in glass Petri dishes (n=5) feeding 3 bees *ad libitum* as mentioned above. After three days, six female mites were incorporated per dish, and their mortality was registered at 24, 48, and 72 h. Results were analyzed by ANOVA and means were compared with the Tukey test. Soluble protein in bees fed with the CFS was significant different respect to controls ($p<0.05$). Toxicity against *V. destructor* was observed for CFS with a 56.6% of effectiveness with differences respect to controls ($p<0.05$). Non statistical differences were detected in mRNA expression levels of Vg, Ilp2, Dom, Hym and Ppo between treatments. Further studies are needed to consider *Lactobacillus johnsonii* AJ5 CFS as a natural alternative for the enhancement of bee health.

Insects trigger a multifaceted innate immune response to fight microbial infections. We previously demonstrated that a response to microorganisms (bacteria and yeast) infection is the induction of N-β-alanyldopamine (NBAD) synthesis in the insects epidermis. Here we show for the first time the ability of entomopathogenic filamentous fungi to induce that special innate immune response (SIIR) through the induction of NBAD- synthase. We tested the pathogenicity of two novel strains of *Beauveria bassiana* selected for their infectivity in dipterans (strain 436) and coleopterans (strain 075) in the Medfly *C. capitata* and in the mealworm *T. molitor*. We here demonstrated the induction of the NBAD- synthase in cell-free extracts of both insects.

We show that *B.bassiana* 436 is pathogenic for *C.capitata* when topically administered with a suspension of 1.10^6 conidia/mL. When infected, survival in the medfly was 19 ± 1.73 days compared to controls 32 days (Test Mantel-Cox p=0.00284 (S). No significant differences were observed between sexes. Surprisingly, the strain 075, entomopathogenic for coleopteran, also proved to be infective for diptera using a puncture method ($p<0,05$).

Larval malformations in *C. capitata* were observed in sublethal infections with the strain 436 in *C. capitata*, whereas strain 075 induced in some cases unusual cuticle tanning in *T. molitor* adults. Although the insects reinforced the cellular and humoral main immunological system by expression of the SIIR they were unable to neutralize the fungal infection.

GnIH downregulates reproductive function in vertebrates. Moreover, there are reports that propose that GnIH acts as an orexigenic peptide in birds and mammals. Previously, we characterized *Cichlasoma dimerus'* GnRH variants (sGnRH, sbGnRH, cGnRH), the orexigenic peptide Neuropeptide Y (NPY) and GnIH peptide, and demonstrated that GnIH inhibited gonadotropin but stimulated growth hormone release in adults of this specie. The general ob-

jective was to start studying GnIH as a link between feeding and reproduction in *C. dimerus*. We evaluate possible morphological relationships between neurons and fibers of GnIH, GnRH variants and NPY, and we analyze variations in the expression of those peptides in animals after fasting. By double label confocal immunofluorescences, we found that neurons of the *nucleus olfacto retinalis* (NOR) co-expressed GnIH and sGnRH, and that some fibers co-expressed both peptides while others were immunoreactive (-ir) to each one at hypothalamic level. There were no contacts between sbGnRH or cGnRH fibers with GnIH neurons in the NOR. GnIH-ir neurons of the hypothalamus did not co-express any GnRH variant. GnIH-ir fibers were observed in close proximity to NPY-ir fibers at hypothalamic level and few contacts between cGnRH-ir and GnIH-ir fibers were observed in midbrain. On the other hand, animals were isolated in aquaria and daily fed at a fix time. After an adaptation period, they were randomly assigned to feeding or fasting groups. Four weeks later, variations in mRNA levels of those peptides were determined by real time PCR in telencephalon, hypothalamus and medium-posterior brain. Fasting conditions induced a significant decrease in GnIH mRNA levels ($p=0.0375$) in the hypothalamus, a clear tendency of decreasing in NPY expression but no changes for GnRH variants in telencephalon and medium-posterior brain. Taking into account our results, we proposed that GnIH could act as a link between feeding status and reproduction in *C. dimerus*.

Recent studies have reported how pesticides impact on bees, affecting their behavior and survival. The main pollutants in bee colonies are due to chemical control of *Varroa destructor*, an ectoparasite mite of *Apis mellifera*. It has been shown that the nutritional quality of *A. mellifera* diet appears to play an essential role in honey bee health, particularly in the presence of pesticides. In this work, we examined the effect of phytochemicals (p-coumaric acid, indole-3-acetic acid and gibberellic acid) in lifespan of honey bees. Besides, we evaluated if administration of phytochemicals in the diet increases the tolerance of bees to a synthetic acaricide, by stimulation of detoxification mechanisms. We conducted a series of longevity assays with nurse bees fed with sugar syrup in the presence or absence of p-coumaric, indole-3-acetic acid and gibberellic acid. Then, bees were exposed to DL_{50} of fluvalinate topically. We further explored if administration of indole-3-acetic acid in the diet can impact the expression of mRNA of genes involved in detoxification pathways. Indole-3-acetic acid enhanced tolerance of fluvalinate (log-rank: 3.823; $p \leq 0.05$); p-coumaric acid had a similar effect, although of reduced magnitude (log-rank: 2,433; $p \geq 0.05$) and gibberellic acid did not produce a significant result. mRNA expression of cytochrome P450 6AS4 and carboxylesterase genes was upregulated in bees fed with indole-3-acetic acid diet. Although, in bees with indole-3-acetic acid diet exposed to fluvalinate, the expression of these genes was lower than in not exposed bees. The expression of cytochrome P450 9Q3 was downregulated in bees fed with indole-3-acetic acid diet. Our results underscore the importance of phytochemicals naturally present in nectar and pollen, and their influence in honey bee longevity and pesticide stress.

Apis mellifera; *Varroa destructor*; phytochemicals; detoxification; nutrition.

(1236) **PROLACTIN INDUCING FACTORS ARE UP-REGULATED IN THE HYPOTHALAMUS OF THE SOUTH AMERICAN PLAINS VIZCACHA FROM MID-PREGNANCY**

Santiago Andrés Cortasa, Sofía Proietto, Schmidt Alejandro Raúl, Pablo Felipe Ignacio Inserra, Santiago Elías Charif, María Clara Corso, Alfredo Daniel Vitullo, Julia Halperin, Verónica Berta Dorfman
CEBBAD, Universidad Maimónides

Abstract: Considering that prolactin (PRL) promotes luteal steroidogenesis in rodents and that the South American plains vizcacha (*Lagostomus maximus*) shows ovulation with corpora lutea (CL) formation at mid-gestation, with increased hypophyseal PRL and CL PRL receptor (PRLR) expression, we investigated the effect of PRL over the expression of hypothalamic factors related with its own production throughout the reproductive cycle of *L. maximus*. Firstly, adult non-pregnant (both non-ovulating and ovulating) and pregnant (early-, mid-, and term-gestation) vizcachas (n=5 per group) were used to study hypothalamic PRLR and tyrosin hydroxylase (TH) immunoexpression and their colocalization by immunofluorescence with confocal microscopy. In addition, we developed a hyperprolactinemia model by injecting non-pregnant females with two doses of 10 mg/Kg sulpiride during 7 days (SULP, n=5) to study the influence of PRL over the expression of its modulators. Animals injected with vehicle were used as controls (CTL, n=5). ANOVA followed by Bonferroni or *t*-test were used to determine significant differences among groups ($p<0.05$). PRLR and TH expressions were studied in arcuate nucleus (ARC). Significant increments in immunoreactive PRLR and TH areas, and in the number of neurons with expression of both markers, were detected in mid- and term-pregnancy related to the other groups. Regarding to the hyperprolactinemia model, the efficiency of sulpiride was confirmed by a significant increase ($p<0.05$) in the hypophyseal PRL immunoreactivity in SULP vs CTL. In the hypothalamus, ARC Immunoreactive PRLR area and, PRLR and TH colocalization were significantly increased in SULP vs CTL. These results suggest a hypothalamic regulation of PRL expression in the vizcacha from mid-pregnancy which supports its involvement in CL formation and maintenance of ovulation from mid- and up to the end of pregnancy of *L. maximus*. GnIH is a dodecapeptide that belongs to the RFamide family. Its acts on the pituitary to inhibit gonadotropin (GTH) release in birds and mammals, but this function in other vertebrates is unclear. Previously, in our lab, we showed that GnIH inhibited GTH and stimulated growth hormone (GH) release in adult of *C. dimerus*. We also studied the ontogeny and we found that GnIH is expressed in neurons of the *nucleus olfacto retinalis* (NOR) and the *nucleus posterioris periventricularis* (NPP). GnIH immureactive (-ir) fibers were widely distributed in the brain and other cephalic regions, even in the pituitary. Our first goal was to study if the expression of GnIH presents variations related to changes in the feeding and gonadal development during ontogeny. Our second goal was to evaluate a possible co-expression of GnIH and GnRH variants, and also if there were contacts between GnIH fibers and GTH and GH cells. Methodology: larvae were obtained from 4 independent spawnings. Samples were taken from hatching to 85 days post-hatching (dph) and processed for immunohistochemistry/double label immunofluorescence or real time PCR. Neurons of both nuclei were quantified (repeated measures AN0VA) and measured. We observed that the number of neurons in the NOR increased by 17 and 85 dph ($p<0.01$), and in the NPP by 14 and 85 dph ($p<0.01$). No changes were observed in the size of NOR (14±3μm) or NPP (8±2μm) cells. mRNA of GnIH was detected on day 1, with an increase in its levels

between 12-20 dph. Analyzing the co-expression of GnIH and GnRH variants, we observed that NOR neurons co-expressed GnIH and salmonGnRH. We found contacts only between GnIH-ir fibers and GH-ir cells at pituitary level. Considering that gonadogenesis begins and the yolk-sac is completely consumed by 12 dph, these results indicate that GnIH could act in the regulation of both processes. The present work comprises starting point for future experiments about the role of GnIH in the development of teleost fish.

Proper control of cholesterol transport is crucial for physiological homeostasis in most eukaryotic cells, although the underlying mechanisms of this process remain unclear. We describe a novel role for endocannabinoid signaling molecules in cholesterol trafficking mechanisms. Loss of polyunsaturated fatty acids (PUFAs) greatly enhances the dauer constitutive phenotype of DAF-7/TGF-β *Caenorhabditis elegans* mutants, which are already intrinsically deficient in intracellular sterol trafficking. Further biochemical and functional analysis established that this exacerbated phenotype is provoked by suppression of the synthesis of the PUFA-derived endocannabinoids 2-arachidonoyl glycerol and anandamide. These endocannabinoids not only rescue the arrest brought on by PUFAs deficiency, but also abolish the larval arrest caused either by impaired cholesterol trafficking (derived from either defective synthesis of glucosylceramides or from deficiencies in Niemann-Pick C1 (NPC1)-like proteins) or by cholesterol starvation of wild type worms for two generation. Thus, endocannabinoids play a pivotal role in C. elegans development acting as regulators of nematode cholesterol transport processes. These findings reveal a previously unsuspected mechanism for the physiological activities of endocannabinoids, uncovering new opportunities for therapeutic intervention in cholesterol disorders.

Instituto de Investigación y Tecnología en Reproducción Animal.

Some authors associate active caspase 3 with events of cell proliferation and differentiation. With the objective of establishing the role of this protein during the events of the ontogeny in *Columba livia*, detection of active caspase 3 was carried out in histological preparations of C. livia. corresponding to stages (E) 40-43 and neonates by inmunohistochemical (IHQ). Were tested using an active anti-caspase 3 antibodies 1:600 and developed according to the indirect “L-streptoavidin biotin” protocol. Expression of said protein was examined at quantitative level via Western Blot (WB). By IHQ said molecule was expressed in the left ovary from the E41. In contrast, oogonias dispersed in the right gonad, do not express active caspase 3, indicating that these, in the right gonad, do not enter into meiosis. Previous determinations by TUNEL and by IHQ for bax were positive, indicating in these cells apoptosis by another common effector caspase different from 3 or by another mechanism of programmed cell death. The expression of caspase 3 active in oogonia in division allows inferring that this molecule would be involved during the gonadal ontogeny in the processes of cell division. This inference is confirmed by the previously presented results of the expression of GnRHR in ogonias from E41, at which point the cells are in cell division. By WB, an increase in the expression of caspase 3 was detected from E41, indicating the onset of meiosis at this time. Taken together with the results of IHQ, these data indicate that active caspase 3 is expressed in the embryonic ovary from E41 and its expression is gradually increased, concomitantly to the increase of germ line cells entering meiosis. Therefore, active caspase 3 is not a key regulator of apoptosis in *C. livia* gonads since positive immunodetection is associated with germline cells in differentiation.

Exposure to environmental stressors during early development has important implications for the rescheduling of many cellular and molecular mechanisms. In many fish, environmental stressors like high temperatures (HT) increase cortisol levels that in turn induce gonadal masculinization of genotypic females, overriding genetic factors related to gonadal development. Here, we show for the first time that the CNS is acting as the transducer of environmental stressors-induced gonadal masculinization. The mRNA of Corticotropin-releasing hormone b (*crhb*) and its receptors (*crhr1* and *crhr2*) were elevated at HT during the critical developmental period when the gonadal primordium was sexually labile. Mutations of both *crh* receptors by CRISPR/Cas9 in genetic female medaka embryos prevented them to masculinize when exposed to HT. However, some XX individuals exhibited an intersex gonad (testis-ova) with the loss of *crhr1* function. The prevention of masculinization in the *cas9*+sgRNA-*crhr1* and -*crhr2* injected larvae was likely due to the lack of Acth release from the pituitary gland, which in turn did not induce cortisol production, the downstream effector of the hypothalamic-pituitary interrenal (HPI) axis. Finally, we could rescue HT-induced female-to-male sex reversal in *cas9*+sgRNA-*crhr2* injected embryos by the addition of cortisol. Taken together, these results revealed the importance of the central nervous system (CNS) as the transducer of stress-induced masculinization in genetic females.

(1886) **CRISPR/CAS9 GENOME EDITING IN *Drosophila melanogaster***

Emiliano Vilardo (), Rolando Rivera-Pomar (1,2), Carla Layana (1)

(1) CREG, UNLP. (2) CITNOBA, UNNOBA.

Drosophila melanogaster, has been used as a model organism for developmental studies for more than 40 years. Investigation in *Drosophila* developed a set of sophisticated techniques for the study of gene function. Genome editing technologies take advantage of RNA-guided nucleases, which can generate directed mutagenesis in selected targets in the genome. In this study, we show the ability of the CRISPR/Cas9 technique to generate mutant alleles that enable the study of spermatogenesis and the role of small ORFs (sORF) in development. We designed and produced five sgRNA expressing plasmids to target *me31B* and two to target sORF-7; and initiated preliminary studies to validate the genome editing in both loci. The proposed objectives are to generate mutations within *me31B* and sORF-7 loci through the injection of sgRNAs expression vectors in blastoderm embryos and to screen for mutant alleles via the use

of PCR techniques. We generated a deletion in the *me31B* locus through the injection of a combination of two plasmids in *vasa-cas9* and *nos-cas9* embryos. In *vasa-cas9* embryos analyzed 24hs post-injection we found fragments indicative of the amplification of a deletion, however, the embryos did not fulfill their life cycle. In contrast, after injecting *nos-cas9* embryos we obtained adult viable flies in which progeny we revealed the fragment indicative of the deletion via PCR. The CRISPR-Cas9 technology proved to be useful to point out the critical role of the sORF-7 in the development of *Drosophila*. We obtained high levels of embryonic lethality with percentages of up to 90% when injecting the plasmids in *act-cas9* embryos. These results indicate that the sORF-7 is transcribed, at least, from the zygote's DNA and is required for the proper development of the egg. The biological function of sORF-7 remains unknown and opens the possibility to assess the importance of other sORFs using this method.

(618) **5-HT2A RECEPTOR IN MPFC CONTROLS CONTEXT-GUIDED RECONSOLIDATION OF LONG- TERM OBJECT MEMORY IN PERIRHINAL CORTEX**

Juan Facundo Morici, Magdalena Miranda, Francisco Gallo, Belen Zanoni Saad, Pedro Bekinschtein, Noelia Weisstaub
FAVALORO - CONICET - INECO

The object recognition memory retrieval is a complex process that required the interaction of multiples structures. It has been proposed that mPFC interacts with the hippocampus during contextual-guided versions of the spontaneous object recognition paradigm. Using a pharmacological disconnection experiment, we have shown that mPFC 5-HT2aR modulation and hippocampus (HIP) interacts in an ipsilateral way during the resolution of an object-in-context recognition memory task. Since the information regarding the identity of the object could be stored in other structures such as the perirhinal cortex (PRH) then, the mPFC-HIP interaction could control the reactivation/reconsolidation in the PRH. To test this idea, we infused a 5-Ht2aR antagonist (MDL) in mPFC before the reactivation phase and immediately after a protein synthesis inhibitor (EME) in the PRH or dorsal dHIP. We also evaluate the interaction between the ventral hippocampus (vHIP) and the mPFC using a disconnection approach. We infused MDL in mPFC and muscimol in the vHIP before the retrieval and EME in the PRH after the reactivation session. We found that blocking 5-HT2aR signaling in the mPFC affects the reconsolidation in the PRH but not in the dHIP. In the disconnection experiment, only contralateral infusions made memories for both objects susceptible to the action of EME. Our results suggest that the interaction between mPFC 5-HT2a modulation and HIP activity controls the reconsolidation of object memory traces in PRH during the retrieval phase.

(1721) **ENDOGENOUS ANTIOXIDANTS AND OXIDATIVE STRESS ON COGNITIVE DIFFICIENCIES**

María De La Paz Scribano Parada, María Luz Garagiola, Emilia De Grazia, Tomas Augusto Castillo, Mariana Tarán, María Del Carmen Baez, Ariel Balceda, Sergio Blencio, Carla Buonanotte, Monica Moya
Cátedra de Física Biomédica. Facultad de Ciencias Médicas. Universidad Nacional de Córdoba.

Introduction: Oxidative stress is identified as a fundamental component in the onset and maintenance of vascular pathologies. In neurocognitive disorders (TNC) the oxidative mechanisms are altered. Nitric oxide (NO) plays a key role in these processes, whereas superoxide dismutase (SOD) is part of the endogenous antioxidant system. Objective: To study in patient the relationship between NO and SOD values and the cognitive state. Material and Methods: Include all subjects who agree to participate and signed informed consent. Demographic data and cardiovascular risk factors were assessed. Patients with pathologies with increased oxidative stress were excluded. The Montreal cognitive test (MoCA) was performed to establish cognitive status. Nitric oxide (NO) (**µ**M) and superoxide dismutase (SOD) (U / ml) were quantified by spectrophotometry. The relationship between variables was analyzed by linear regression analysis, level of significance p <0.05. Results: 96 patients were evaluated, 18 were excluded. Female gender was defined. Age: 68.28 ± 11.90. Years of schooling: 08,13 ± 04,04. MoCA: 22.36 ± 6.30. Hypertension, sedentary lifestyle and dyslipidemia were the most prevalent cardiovascular factors. From the analysis of the linear regression between the values of NO plastic observed an increase of 0.27 points in the MoCA test for each 3.24 uM of NO; CI = LI (95%) 8.63-S (95%) 32.85 (p = 0.0011). While there is a decrease (0.16 points) in MoCA with increasing SOD; IC = LI (95%) 179.46 - LS (95%) 293.27 (p <0.0001). Conclusions: The excessive generation of free radicals leads to oxidative, nitrous, or both, damaging proteins, lipids and DNA. The brain is more susceptible to oxidative damage because of its high metabolic rate, high polyunsaturated lipid content, and lower levels of endogenous antioxidant activity and protection mechanisms. An increasing number of studies indicate that oxidative stress correlates with the pathogenesis of AD, and vascular dementia

(189) **EFFECT OF GEOMETRICALLY DIFFERENT ENVIRONMENTS AS NOVELTY ATTRACTORS ON THE LATERALIZED EXPLORATORY RESPONSE IN MATURING RATS**

Silvia G. Ratti, Renata Lario, Edgardo O. Alvarez Toro
Lab Neuropsicofarm Exptl, FCM, UNCuyo, IMBECU-CONICET

It is known that the brain is functionally lateralized to control several biological responses in man and animals. However, its intrinsic neural mechanisms are not known. Previously in our laboratory, results were shown that in the Double Hole-Board Labyrinth (LDHB), maturing normal rats show a left-biased exploration induced by novelty. Since the LDHB is composed of two solid rectangular compartments disposed in 90º to each other (inverted "T" form), question was raised if the rat's brain lateralized behavioural response should be constant in any geometrically shaped environment. The answer to this question should enlighten the possible plasticity in the lateralized responses of the animal. Maturing normal rats at 30 days of age were used. They were tested in the LDHB (n=20) as a complex geometrical environment (SRT); in a rectangular cage (n=18), as a rectangular environment (SR), and a cubic cage (n=18), as a square environment (SQ). Exploration activity was video recorded and measured by digital automatic counter. Results are expressed as Counts/min. Results shown that in the SQ, right-biased exploration was found (74.5±9, left side Vs 118±12, right side, p<0.01), with a percentage of 77.8 of right explorers. In the rectangular environment, no left or right preference was found (47.5±10, left side Vs 84.5±9, right side, n.s.); and in the LDHB, left-biased exploration was found (75.5±9 left side Vs 37.5±3 right side, p<0.01), with a percentage of 70% of left explorers. In conclusion, results show that the spontaneous natural biased exploratory response showed by animals is depending on the geometry of the novel environment, suggesting that in the rat's brain the lateralized neural circuits are modulated by the geometric aspect of the environment.

(1808) **NEUROPEPTIDE W30 IMPROVES HIPPOCAMPAL-DEPENDENT MEMORY AND SYNAPTIC TRANSMISSION BY PROMOTING NOS1 AND CREB EXPRESSION**

(4) Functional Pharmacology, Department of Neuroscience, Uppsala University, Uppsala, Sweden.

Homeostatic regulation of feeding and energy balance involves cognitive, emotional, sensorial and autonomic events, as well as the activity of a highly integrated and redundant neurohumoral system. Neuropeptide W (NPW) is part of this complex net. There are two mature forms derived from a common precursor peptide, pro-NPW, by proteolytic processing: NPW30 (the 30 amino acids form) and NPW23 (consisting of 23 amino acids). The peptide and its receptors are present in the rat hippocampus, amygdala, hypothalamus, and pituitary. We have previously found that hippocampal administration of NPW30 increased latency time in the step-down test. Objective: to assess the effect of hippocampal NPW30 acute administration on neuroplasticity and expression of several genes related to the molecular cascade of memory in rat hippocampus. Male adult rats were infused into the hippocampus with artificial cerebrospinal fluid (Control group) or NPW30 (0.3 and 3 nmol/µl) and 24h later, the hippocampus was dissected to perform electrophysiological procedure (n=5/each group) or RT-PCR (n=10/each group). Statistics: Student's t-test or ANOVA followed by Bonferroni. The highest dose of NPW30 reduced the threshold to generate long term potentiation (LTP) (NPW30, 3 nmol/µl: 31.67±5.43 Hz vs. Control: 90.00±17.32 Hz; $P<0.05$) and increased the relative expression of cyclic AMP response element binding protein (CREB) 1b ($F(27,2)=8.07$; $P<0.05$) and neuronal nitric oxide synthase (NOS1) ($F(23,2)=9.31$; $P<0.05$). It has been demonstrated that NOS1 activity is relevant in early stages of memory formation, and CREB is a transcription factor that plays a key role in the hippocampal plasticity, especially in LTP induction and maintenance and long term memory establishment. In conclusion, these findings suggest that NOS1 and CREB participate in the mechanism by which NPW30 can modulate neuroplasticity and behavioral expression of memory.

Keywords: Neuropeptide W30, NOS1, CREB, LTP, memory.

(558) **POSITIVE EMOTIONAL INDUCTION INTERFERES WITH THE RECONSOLIDATION OF NEGATIVE AUTOBIOGRAPHICAL MEMORIES.**

Marcelo Piñeyro (1), Roque Ignacio Ferrer Monti (1), Adrian Bueno (1), Hugo Díaz (2), Victor Molina (2), Silvia Bustos (2)
(1) Laboratorio de Psicología experimental, Facultad de Psicología, Universidad Nacional de Córdoba. (2) IFEC-CONICET, Departamento de Farmacología, Facultad de Ciencias Químicas, Universidad Nacional de Córdoba.

After reactivation, a previously consolidated memory can enter into a labile state followed by a re-stabilization process defined as reconsolidation. The aims of this study were to explore whether an existing negative autobiographical memory can be modified by using a non-invasive interference (audiovisual positive preparation) after reactivation and to determine if this effect could be dependent on the reconsolidation process.

Participants 'memories were reactivated on day 1 (retrieval session) by means of the Autobiographical Memory Test (AMT) by the presentation of the negative adjective "angry" and they were instructed to remember one specific event from their own past and to write down the event in 4 min. Ten min later half of the subjects were shown the positive audiovisual inductor (POSITIVE INDUCTOR, PI group) and the other half was shown an equivalent neutral audiovisual inductor (NEUTRAL INDUCTOR NI group). The memories were tested 7 and 30 days later by means of the presentation of the title of the event and they had again 4 min to write down the event. The results shown that only in women the presentation of a positive inductor reduced significantly the negative emotional content 7 and 30 days later (post hoc, $p< 0.05$).

In sum, we found that a positive emotional experience after a negative autobiographical memory reactivation may lead to a change in the emotional information of the original trace and that such effect can be mediated by the reconsolidation process. These results suggest that a positive audiovisual induction may play a potential role in psychotherapeutic techniques for the modification of dysfunctional autobiographical memories.

(1700) **ROLE OF THE SEROTONERGIC RECEPTOR 2a (5-HT2a) IN COGNITIVE FLEXIBILITY**

María Belén Zanoni Saad (1), Facundo Morici (2), Francisco Gallo (2), Pedro Bekinschtein (2), Noelia Weisstaub (2)
(1) Laboratorio de Comportamiento y Cognición Experimental. Instituto de Fisiología y Biofísica Houssay, Facultad de Medicina, UBA-CONICET. (2) Instituto de Neurociencia Cognitiva y Traslacional, Favaloro - INECO – CONICET.

Living organisms inhabit environments that are being permanently modified, so adapting their behavior to such changes could determine their survival. The concept of "cognitive flexibility" refers to this ability and serotonin (5-HT) has been identified as an important player in decision making. So, it would be reasonable to assign the serotonergic system a major role in processes of cognitive flexibility. Pharmacological experiments support this statement. However, it is still questionable which are the receptors that mediate these processes.

One of the most important post-synaptic receptors of the serotonergic system is the type 2A (5-HT2aR). This receptor is highly expressed in the limbic system as well as frontal regions of the cortex and has been associated with various psychiatric disorders. The lack of specific antagonists makes complex the identification of its function. Then, we assessed the role of the 5-HT2aR using protocols of extinction and reversal learning as measures of cognitive flexibility in genetically modified mice. Our preliminary results indicate that WT mice extinguish a fear conditioned memory faster than 5-HT2a$^{-/-}$ mice (two-way ANOVA, $p<0.01$). This would indicate that 5HT2aR is necessary for cognitive flexibility.

Since cognitive rigidity is a common behavior symptom of many psychiatric disorders, it has clinical relevance to identify its underlying neurobiological substrate to generate new and specific pharmacological tools.

Palabras clave: cognition, behavior, serotonin.

(242) **SENSITIZATION-DEPENDENT NICOTINE PLACE PREFERENCE IN THE ADULT ZEBRAFISH**

Antonella Pisera Fuster, M.paula Faillace, Ramon Bernabeu
IFIBIO.

Tobacco smoking is a risk factor for subsequent cocaine abuse, but the neural substrates underlying this risk remain unknown. Locomotor sensitization is a robust and readily assayed effect of psychostimulants, while conditioning place preference (CPP) is a more naturalistic model of addictive behavior. To understand the biological basis of nicotine induce reward, we analyzed first sensitization to nicotine and/or cocaine in zebrafish by exposing animals five days (20 min-day) to either drug followed by five days of abstinence before a challenge dose. We tested next if sensitized zebrafish can induce nicotine place preference using a biased design. Locomotor sensitization was increased by 103% with nicotine and 166% with cocaine. In addition, both nicotine and cocaine previously sensitized animals showed positive nicotine CPP, using a nicotine dose that cannot generate CPP by it self. Zebrafish sensitization and CPP was corroborated by behavioral analysis of several indicators of drug exposure and preference, such as locomotor activity, time spent in the upper-zone, time spent in the drug-paired side, number of entries to the drug-paired side, and distance traveled. The behavioral results obtained were also accompanied with chances in the expression of some molecular markers, measured by qPCR, such as nicotine receptors subunits, DAT and Pitx3, which are associated with drug reward. These results from zebrafish strongly suggest that repeated exposure to nicotine and/or cocaine induce sensitization by increasing the vulnerability and facilitating the rewarding properties of nicotine, although the dose of nicotine is not sufficient to induce seeking behavior *per se*. The behavioral characterization of these responses in zebrafish may be the first important step towards establishing this species as a tool for the analysis of molecular and neurobiological mechanisms underlying human drug seeking behavior.

Keywords: Sensitization, nicotine, cocaine, zebrafish, CPP.

(671) **UNDERSTANDING MEMORY LOSS: DEVELOPMENT OF A RETRIEVAL-INDUCED FORGETTING PARADIGM IN RODENTS**

Francisco Tomás Gallo, Juan Facundo Morici, Magdalena

Miranda, Noelia Weisstaub, Pedro Bekinschtein
FAVALORO - CONICET - INECO

In the last two decades there´s been a growing human literature on a phenomenon called retrieval-induced forgetting (RIF). RIF has pointed to inhibitory control processes that resolve retrieval competition as a cause of adaptive forgetting. Using spontaneous recognition memory in rats, we have developed a rodent paradigm for RIF. We were able to show that forgetting of an item associated with a particular context happens under conditions that cause competition between memory traces for two items that share a particular retrieval cue. Under these conditions, forgetting is long lasting and independent of the selected retrieval cue. We used local pharmacological inactivation to show that this kind of forgetting requires the activity of the medial prefrontal cortex (mPFC). With pharmacological inactivation, we showed that the Ventral Tegmental Area (VTA) is necessary for the forgetting to occur and that the infusion of a D1/5 agonist in the mPFC is sufficient to rescue the expression of the RIF phenomenon impelled by the inactivation of the VTA. These results are consistent with the idea that the RIF occurs via a top-down inhibitory control mechanism exerted by the mPFC on structures linked by hypothesized memory traces. With the latter results, we bring new evidence supporting the role of dopamine in the resolution of interference via mPFC inhibitory control.

(1932) **SURVIVAL AND DIFFERENTIATION EFFECTS OF PIGMENT EPITHELIUM DERIVED FACTOR (PEDF) ON RETINA NEURONS**

Luis Politi (1), German Michelis (1,2), Lorena German (1), Patricia Becerra (2), Nora Rotstein (1)
(1) Instituto de Investigaciones Bioquímicas (INIBIBB), Universidad Nacional del Sur (UNS)-CONICET, Bahía Blanca, Argentina. (2) NEI-NIH, Bethesda, MD, United States.

PEDF promotes survival of photoreceptor cells and in an R28 retinal progenitor cell line by binding to PEDF membrane receptors. However, the intracellular molecular effects of PEDF in retina neurons are still unknown. Here we investigated these effects using pure neuronal cultures of photoreceptors and amacrine neurons, prepared from newborn rat retina and grown in a chemically defined medium. Cultures were supplemented at day 2 with either recombinant human PEDF (10 nM); PEDF plus P1 (a PEDF receptor blocking peptide, 100nM); or vehicle (control). At day 5, cells were fixed and cell death and apoptosis were evaluated by DAPI staining, Propidium Iodide and TUNEL assays, respectively. Mitochondrial activity was assessed with Mitotracker and opsin expression and axonal outgrowth were determined by immunocytochemical methods.

PEDF decreased the percentages of Propidium Iodide and TUNEL-positive photoreceptors by 55% and 65%, respectively, with respect to controls without PEDF, and significantly prevented the loss of mitochondrial membrane potential. Pre-incubation with the blocking P1 peptide abolished PEDF effects. PEDF had no effect on opsin expression but promoted its apical localization in photoreceptors as occurs in mature retinas, in contrast to its diffuse distribution on the cell body in controls. PEDF also stimulated axon outgrowth in amacrine neurons, by 2-fold, in neurons treated with PEDF, compared to controls. These effects were blocked by the blocking P1 peptide pre-treatment.

In summary, this work shows that PEDF acts as a survival factor for photoreceptors, preserving their mitochondrial functionality, and induces the differentiation of amacrine and photoreceptor neurons during their development in vitro.

Keywords: PEDF, apoptosis prevention; retina photoreceptors; amacrine neurons

(1935) **SUPERIOR CERVICAL GANGLIECTOMY INDUCES DRY AGE-RELATED MACULAR DEGENERATION IN MICE: A NEW EXPERIMENTAL MODEL**

Hernán H. Dieguez1, Horacio E. Romeo2, María F. González Fleitas1, Marcos L. Aranda1, Georgia Milne1, Ruth E. Rosenstein1, Damián Dorfman1

1. Laboratorio de neuroquimica retiniana y oftalmología experimental, Departamento de Bioquímica Humana, Facultad de Medicina/CEFyBO, Universidad de Buenos Aires/CONICET, Buenos Aires, Argentina. 2. Facultad de Ciencias Medicas, Universidad Pontificia Catolica Argentina, BIOMED/UCA/CONICET, Buenos Aires, Argentina.

Dry age-related macular degeneration, a prevalent cause of blindness, is a progressive and degenerative disease, characterized by alterations in Bruch´s membrane, retinal pigment epithelium, and photoreceptors exclusively localized in the macula. Despite there are experimental murine models, the vast majority take too long to develop retinal alterations, which in general are ubiquitous, many result from non-eye specific genetic manipulations, and most do not always reproduce the hallmarks of human age-related macular degeneration. Choroid vessels receive sympathetic innervation from the superior cervical ganglion, which together with the parasympathetic system, regulate the blood flow. Choroid blood flow changes have been involved in age-related macular degeneration development and progression. At present no experimental models take this factor into account. The aim of this work was to analyze the effect of superior cervical gangliectomy on the choroid, Bruch´s membrane, retinal pigment epithelium, and retina. Adult male C57BL/6J mice were submitted to unilateral superior cervical gangliectomy and a contralateral sham procedure. Although superior cervical gangliectomy induced ubiquitous choroid and choriocapillaris changes ($p<0.01$), it induced Bruch´s membrane thickening, retinal pigment epithelium melanin content and retinoid isomerohydrolase loss, drusen-like deposit occurrence, and retinal pigment epithelium and photoreceptors atrophy, exclusively localized in the temporal side ($p<0.01$). Moreover, superior cervical gangliectomy provoked a localized increase in retinal pigment epithelium and photoreceptors apoptosis ($p<0.01$), and photoreceptors electroretinographic function decline ($p<0.01$). Therefore, superior cervical gangliectomy recapitulated the main features of human dry age-related macular degeneration, and could become a new experimental model of dry age-related macular degeneration, and a useful platform for developing new therapies.

Keywords: age-related macular degeneration, superior cervical ganglion, choroid, retinal pigment epithelium, experimental model.

(1530) **OLIGODENDROCYTES MATURATION AND METABOLIC PROFILE UPON IRON DEFICIENCY**

Maria Eugenia Guitart (1), Maria Victoria Rosato-Siri (1), Pamela Victoria Martino Adami (2), Sandra Verstraeten (1), Laura Morelli (2), Juana Maria Pasquini (1)
(1) IQUIFIB-CONICET. (2) IIBBA-CONICET

Iron deficiency (ID) represents one of the most prevalent nutritional deficits, affecting almost two billion people worldwide. Gestational iron deprivation as an experimental model is a useful tool to describe specific oligodendrocyte (OL) requirements for progression to a mature and myelinating state. Previous work demonstrated that ID-OL appear to exhibit intrinsic alterations in terms of proliferation, migration and maturation.

To better understand OL maturation, we explore the hypothesis that ID constrains OL maturation by impairing metabolic pathways. *In vivo* and *in vitro* studies were conducted to evaluate: a) OL lineage composition along ontogenetic myelination; b) OL lineage cell number regulation; c) Glial cell metabolic profiles. We used an eGFP::CNPase transgenic mouse which renders the whole OL-lineage-committed cells as green-fluorescent (CNPase-positive cells). Pregnant mice were fed an ID diet (4mg/g/kg) as from gestational day 5. Postnatal development of myelination was evaluated 15 and 30 days after birth (PND15 and 30). At PND15, ID-OL lineage exhibited an increase in CNPase-positive cells but this redundancy failed to attain complexity and maturity ($p\leq 0.01$). At PND30, the number of CNPase-positive cells decreased, through an increase in cell death ($p\leq 0.01$).

To further describe ID effects, the correlation was explored between maturational stage and ID metabolic signature. Energy me-

tabolism was assessed in OL and astrocyte (AST) primary cultures from newly born ID WT pups. Measurements of glycolysis and mitochondrial respiration showed that ID glial cell (OL and AST) maximum rate of respiration was lower than control ones ($p \leq 0.001$). In addition, control AST exhibited a higher basal glycolitic capacity than ID AST ($p \leq 0.001$). These findings further prove that the regulation of cell metabolism may impact cell fate decisions and maturational status.

Keywords: Iron deficiency, maturational status, metabolic pathway

(1172) **GLUN2A KNOCKDOWN UP-REGULATES SYNAPTIC PROTEIN EXPRESSION IN MATURE PRIMARY NEURONAL CULTURES**

Maria Florencia Acutain, Cecilia Vazquez, Diana Alicia Jerusalinsky, Maria Veronica Baez
Instituto de Biologia Celular y Neurociencias "Prof. De Robertis" (IBCN)

It is well recognized that the NMDA receptors (NMDAR) are involved in synaptic plasticity, learning processes and memory, but their specific regulation is little known. NMDAR are composed by two GluN1 obligatory subunits and two regulatory subunits: GluN2 (A-D) or GluN3 (A-B). GluN2A and GluN2B are the most expressed regulatory subunits in hippocampus and other memory related brain structures, where GluN2A and GluN2B transcription and translation are tightly regulated. This results in GluN2B expression in immature synapses, and GluN2A in mature and stable synapses. In order to understand the role of GluN2A during memory acquisition and plasticity induction we built two AAV-eGFP vectors: one of them codifying a shRNA anti GluN2A (AAV-sh2A), and the other carrying a shRNA scramble as control (AAV-shSc). We infected mature primary neuronal cultures with AAV-sh2A or AAV-shSc and analyzed not only the specificity of GluN2A knockdown but also the effects of this decrease on other synaptic protein expression: Synapsin-1 and PSD95. As was expected, we observed by qPCR, a decrease in GluN2A mRNA only in primary cultures infected with AAVsh2A, without changes in GluN1 or GluN2B expression. Interestingly in those cultures, GluN2A decreased expression was accompanied by a significant diminution on GluN1 protein level. Furthermore, GluN2B levels were similar to control cultures infected with the AAV-shSc. On the other hand, we found an increased expression of Synapsin-1 and PSD95 in GluN2A knockdown cultures. These results, suggest that although GluN2A decrease does not change NMDAR subunit expression at transcriptional level, it could activate some postranscriptional regulatory mechanisms that change GluN1 protein levels. Moreover, that change seems to induce a rise in the synapsis without NMDARs increase.

Keywords: NMDAR, neuronal cultures, PSD95.

(1532) **SPATIO-TEMPORAL CHANGES OF APOPTOSIS IN CEREBELLAR PURKINJE CELLS AFTER PRENATAL BLOCKADE OF ANGIOTENSIN II AT2 RECEPTOR**

Rocío Ayelem Conforti, Susana Inés Sánchez, Lucia Beatriz Fuentes
Farmacología. Facultad Química Bioquímica y Farmacia. Universidad Nacional de San Luis

Angiotensin II (Ang II) exerts its physiological effects through binding to two receptor subtypes: AT_1 and AT_2. These are differentially blocked by Losartan or PD123319, respectively. Ang II receptor expression is highly modulated during development. AT_2 receptors are highly expressed in neonatal tissues suggesting a role of these receptors in growth and organogenesis. In cerebellum, AT2 receptors are located only in the Purkinje cells (PC) membrane; these cells are the primary organizer in the postnatal cerebellar corticogenesis. The aim of the present study was to evaluate apoptosis of PC in neonatal cerebellum of animals treated with AT_2 receptor antagonist. Treatment was performed in Wistar rats during the last week of pregnancy with vehicle (control) or PD123319 (AT_2 antagonist, 1.0 mg/kg/day) and offspring were analyzed at different ages: P3, P5, P8 and P15. Apoptosis was evaluated at the different folia of the cerebellar cortex at the level of the vermis using acridine orange staining and fluorescence microscopy. The control pups showed increased apoptosis in PC in P3–P5 respect to P8-P15 ($p<0,001$). Likewise, apoptosis occurs in these animals, following a spatio-temporal pattern similar to that which they follow in their maturation and migration process. Animals born from mothers treated with PD123319 showed a delay in the apoptosis process. In P3 and P5 treated animals had a significantly decreased in the apoptotic process PC ($p<0,001$). In P8, treated animals showed a significant increase respect to control ($p <0.001$). A detailed spatial analysis shows that the significant difference occurs only in posterior folia: X, IX,VIII ($p <0.05$) and anterior folia: III, II, I ($p <0.01$). In P15 there were no significant changes. These results suggest that there is a developmental stage-specific mechanism of apoptosis in cerebellum and that renin-angiotensin system could be involve in growth and organogenesis process of cerebellum.

(1770) **STUDY OF THE IMPACT OF THE PRO-INFLAMMATORY RESPONSE ON THE DIFFERENTIATION OF HUMAN DOPAMINERGIC PRECURSORS**

Shirley Wenker (1), Victoria Gradaschi (1), Maria Farias (1), Corina Garcia (1), Carina Ferrari (2), Xianmin Zeng (3), Fernando Pitossi (1)

Parkinson´s Disease (PD) is a neurodegenerative disorder characterized by the loss of dopaminergic (DA) neurons of the substantia nigra pars compacta. Transplantation of dopamine-producing cells into the striatum has already shown its effectiveness in animal models and clinical trials. Here, we aimed to study the host primary response related to the graft of human DA precursors (DA14) *in vivo* and the impact of pro-inflammatory factors on the viability and differentiation process of DA14 cells *in vitro*. DA differentiation protocol from human neural stem cells was standardized and characterized by immunofluorescence for the following markers: beta III Tubulin (neuronal cells), GFAP (astroglial cells), Foxa2 (DA precursors) and Tyrosine hydroxylase (TH) (DA neurons). We analysed cell population at two stages: DA14 (Foxa2: 71,5%; TH: 5,2%) and final stage, DA28 (beta III Tubulin: 59,4%; TH: 17,4%; GFAP: 3,9%). For *in vivo* assay, DA14 were transplanted into the striatum of adult immunosuppressed rats and host-primary response was analysed by immunofluorescence. Preliminary results showed host-MHCII and GFAP positive cells within the graft after 7 days of surgery. In order to study the effect of microglial activation on DA14 maturation *in vitro*, BV2 microglial cells were activated with bacterial lipopolysaccharides (LPS). DA14 cells were then exposed to conditioned media (CM) from basal and activated BV2 cells for 4 days and TH positive cells were determined at DA28 stage. TH cell counting revealed that exposure of DA14 to CM from activated microglia decreased the number of DA neurons at final stage ($P<0.05$). These findings suggest that, *in vivo*, DA14 cells grafting induced host primary response and *in vitro*, activation of microglia could have a negative impact on survival and/or maturation of DA precursors.

Keywords: Parkinson's disease; inflammation; dopaminergic precursors

(1877) **STUDY OF THE INVOLVEMENT OF CB1 RECEPTOR IN ANXIETY LIKE-BEHAVIOUR RELATED TO ACETIC ACID-INDUCED VISCERAL PAIN IN ADOLESCENT MALE AND FEMALE MICE LACKING CB_1 RECEPTORS**

Eliana Micaela Canero (1), Amira Jazmín Aon (1), Valeria Teresa Pedrón (1), Graciela Noemí Balerio (1,2)
(1) CONICET - Universidad de Buenos Aires. Instituto de Investigaciones Farmacológicas (ININFA). Buenos Aires, Argentina. (2) Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica: Cátedra de Farmacología. Buenos Aires, Argentina.

CB_1 cannabinoid receptors are widely distributed in the central nervous system where they mediate most of the cannabinoid induced responses. Here we evaluated the interaction between the CB_1 cannabinoid receptors and the endogenous opioid system by assaying anxiety like-behaviour related to acetic acid-induced visceral pain in adolescent mice of both sexes.

The elevated plus maze and acetic acid-induced writhing tests were used in order to evaluate the effect of morphine (MOR) on the anxiety like-behaviour associated to visceral pain in mice lacking CB_1 receptors, respectively. CB_1 knockout (CB_1 KO) and their wild-type (WT) littermates mice were pre-treated with MOR (3 mg/kg or 9 mg/kg i.p.) or saline (SAL) injection 20 minutes before acetic acid (1.5%, 10 ml/kg i.p.) or SAL administration, and immediately after, the total number of writhes or anxiety-like responses were registered for a period of 20 min.

We observed significant differences in the *effect of* MOR *on the number of writhes, expressed as percentage of writhing* inhibition. MOR (3 mg/kg) decreased and MOR (9 mg/kg) completely blocked the *number of writhes* compared to their control groups (mice only treated with acetic acid) ($p<0.001$) in both sexes and genotypes. On the other hand, an increase in the anxiety-like behaviour (expressed as the percentage of time and entries in the open arms) was observed in mice only treated with acetic acid ($p<0.01$), in both sexes and genotypes. In addition, MOR 9 mg/kg was able to attenuate the anxiogenic-like effect (expressed as the percentage of entries in the open arms) in CB_1 KO, but not in WT male mice ($p<0.05$). On the contrary, this attenuation was not observed in CB_1 KO female mice ($p<0.05$).

In conclusion, the lack of CB_1 receptor could modulate the anxiety-like behaviour associated to acetic acid-induced visceral pain in male mice pre-treated with MOR but not in females.

(485) **TGF-β AND ITS INTERACTION WITH THE NOTCH SIGNALING PATHWAY ON OLIGODENDROGLIAL DIFFERENTIATION OF ADULT NEURAL PROGENITOR CELLS**

Laura Ivonne Gómez Pinto, Débora Rodríguez, Ana M Adamo, Patricia Mathieu
Departamento de Química Biológica, Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, IQUIFIB-CONICET, Argentina.

Neural progenitor cells (NPCs) from the subventricular zone (SVZ) are the source of new neurons, astrocytes and oligodendrocytes in the adult brain. Both Notch and TGF-β signaling pathways have been shown to act synergistically in co-cultures of mesenchymal stromal cells and NPCs, inducing NPC differentiation into astrocytes and oligodendrocytes. Taking into account the possible participation of NPC in the response mechanisms upon demyelination, the aim of the present work is to study the changes induced by TGF-β and the underlying interplay between TGF-β and Notch signalling on cell populations arising from adult brain SVZ cultures.

Wistar rat adult brain SVZ neurospheres were plated in coated coverslips and cultured for 48 h and then treated with TGF-β for different times. Results obtained 6 days after plating show a significant increase ($p<0.05$, two way ANOVA) in the percentage of glial cell population: PDGFRα+ and GFAP+ cells, concomitantly with an increase in the expression of Notch ligand, Jagged1. Furthermore, Ki67 expression and BrdU incorporation assays rendered a significant increase in total cell proliferation after 24 h culture and a significant increase ($p<0.05$ Student´s t-test) in the proportion of PDGFRα+/Ki67. In addition, 8 day cultures exhibited not only a significant increase ($p<0.05$ two way ANOVA) in the proportion of MBP+ cells but also a higher degree of cell differentiation, as evidenced by the presence of more ramified processes suggesting an effect of TGF-β on differentiation towards a mature oligodendrocyte. TGF-β signaling inhibition resulted in a decrease ($p<0.05$ Student´s t-test) in Jagged1 expression and OPC population; moreover, Notch signaling inhibition showed a decrease in OPC proliferation.

Our results demonstrate the participation of Notch signaling in TGF-β effects on glial cell fate decisions of adult brain SVZ NPCs, as well as on OPC proliferation and maturation.

(1548) **THE BMP PATHWAY IS RECRUITED BY DIFFERENT CIRCADIAN CLUSTERS TO COMMUNICATE TIME OF DAY INFORMATION IN ADULT *Drosophila***

Sofía Polcowñuk, María Fernanda Ceriani
Fundación Instituto Leloir- IIBBA-CONICET

Circadian behavior is controlled by an endogenous clock. In *Drosophila,* this clock resides in about 150 neurons; among them, the sLNvs are particularly relevant to set the free-running period.

To improve our understanding about the communication among different circadian clusters we carried out a miss-expression screen in the sLNvs. This approach uncovered a long period phenotype mutant that affected the levels of a positive regulator of the BMP pathway, a highly conserved retrograde signaling pathway that influences synaptic connectivity through transcriptional control.

Taking advantage of different genetic tools we observed that the activation of the signaling cascade (through expression of a transcription factor or constitutive activated versions of receptors) triggers a long period phenotype, while cluster-specific downregulation of specific ligands triggered loss of rhythmicity under constant conditions compared to controls (statistical analysis included Kruskal Wallis test). To characterize further the steps leading to pathway activation, we examined pMad staining through immunohistochemistry on wild type brains. Interestingly, despite pMad is found exclusively in the nucleus in non-circadian neurons, pMAD is in the cytoplasm in the small and large LNvs suggesting a cluster specific-regulation. In that regard, we explored the possibility that overexpression of the DPP and GBB ligands in specific circadian neurons could increase the amount of pMAD in the nucleus of LNvs neurons. We found that DPP overexpression generates an increase in pMAD nuclear levels exclusively in the LNvs while GBB has no effect (Statistical analysis included a One-way ANOVA).

These results show that not only the BMP pathway is active in LNvs neurons, but also they differentially respond to specific ligands. This finding opens the provocative possibility that the BMP pathway is recruited by different circadian clusters to communicate time information and for fine tuning clock properties.

(30) **PROGESTERONE REGULATES INFLAMMASOME EXPRESSION AFTER SPINAL CORD INJURY: IMPLICATIONS FOR NEUROPATHIC PAIN**

María Celeste Raggio (1), María Florencia Coronel (1), Susana Laura González (1,2)
(1) IBYME – CONICET. (2) Facultad de Medicina – UBA.

Abstract: Neuropathic pain, a frequent complication after spinal cord injury (SCI), is refractory to available treatment. Spinal glial cell activation and production of pro-inflammatory mediators, like IL-1β and IL-18, have a critical role in the development of this chronic pain. Neuroinflammatory processes triggered after SCI involve the activation of multiprotein complexes called inflammasomes, containing three main components: NLRP3, ASC and pro-caspase-1. Caspase-1 processes the precursors of IL-1β and IL-18 to its mature forms. We have shown that progesterone (PG), a neuroactive steroid, prevents pain and exerts anti-inflammatory actions. To analize whether these effects involve the modulation of NLRP3 inflammasome, we studied temporal changes in the expression of its components in the acute phase after SCI. Male rats were subjected to spinal hemisection at T13 level and received daily subcutaneous injections of PG (Hx+PG; 16 mg/kg, n=16) or vehicle (HX, n=16). Uninjured rats were used as control (C). Epicenter spinal cord segments were obtained 1 and 3 days post-injury and the mRNA levels of NLPR3, ASC, IL-1β, IL-18 and P2X7 purinergic receptor, involved in inflammasome activation, were determined using RT-PCR. Injured animals showed a significant raise in NLRP3 ($p<0.05$ vs C) and IL-1β ($p<0.001$ vs C) mRNA levels 1 day after SCI, as well as a clear increase in P2X7 ($p<0.01$ vs C), ASC ($p<0.001$ vs C), NLPR3 ($p<0.001$ vs C) and IL-18 ($p<0.01$ vs C) transcripts 3 days after injury. At this time point, animals treated with PG showed significantly lower levels of NLPR3 ($p<0.01$ vs C; $p<0.05$ vs HX), while P2X7, ASC and IL-18 expression levels remained similar to control values ($p>0.05$ vs C; $p<0.05$ vs HX in all cases). These results suggest that PG, by modulating spinal mechanisms associated with NLRP3 inflammasome activation, could stand as a promising therapeutic alternative for SCI-induced neuropathic pain (PIP CONICET 266,

Fundación Barón, Fundación Williams).

Keywords: Progesterone, inflammasome, chronic pain

(62) **HYPOTHALAMIC- PITUITARY-ADRENAL ACTIVITY AND MEMORY IN THE ELDERLY: A NON INVASIVE APPROACH.**

Alejandro Arregger, Estela María Del Lujan Cardoso, Rocío Sanchez, María Laura Saglio, Liliana Noemí Contreras
Universidad de Buenos Aires, Facultad de Medicina, IDIM ALanari, UE IDIM, Endocrinología Experimental.

Abstract: Daily stress in aging has been linked to detrimental effects on memory. However, associated impairment of the HPA axis regulation remains unclear. The aim of this study was to evaluate the relationship between memory and the cortisol feed-back regulation of the HPA axis in aging women. Seventeen women aged 71.5±7 yo without dementia complaining of poor memory were studied. They obtained whole saliva samples to evaluate the circadian rhythm of salivary cortisol (SAF) by the ratio 8.00 and 23.00 ($SAF_8/SAF_{23} \geq 2$). The HPA axis suppressibility was assessed by the overnight 0.5 mg dexamethasone suppression test (DST). SAF and salivary dexamethasone (Dsa) after DST were determined at 8.00 (SAF_{8dex}, Dsa_8) and at 16.00 (SAF_{16dex}, Dsa_{16}). Quality of life (QL) was investigated by the self administered questionnaire SF36. Episodic, logical, working and semantic memories, visuospatial perception and attention were also assessed. The protocol was approved by the Ethics Committee of the IDIM A. Lanari and all subjects gave their written informed consent. SAF (nmol/L) and Dsa (pmol/L) were determined by RIA and ELISA respectively. Statistics were performed by SPSS ($p<0.05$ was considered significant). Memory impairment (MI) was found in 7 patients who had lower QL (Physical Summary Component: 41±7.5) than 10 patients with normal memory (50.2±7.9) p: 0.008. Fifteen women had normal SAF variation, Dsa and DST suppression ($Dsa_8 \geq 450$, $Dsa_{16} \geq 140$, SAF_{8dex} and SAF_{16dex}: ≤2.0). Two MI patients showed normal SAF variation and adequate Dsa (Dsa_8:768±198, Dsa_{16}:263 ±109), but did not suppress with DST (SAF_{8dex}:2.7±0.2, SAF_{16dex}: 3.5±0.7). Conclusions: Poor QL was associated with MI although the latter is not always related to HPA disregulation. Hippocampal images might contribute to establish an anatomical link between MI and abnormal feed-back regulationm.

(1203) **EFFECTS OF ISOESPINTANOL IN MYOCARDIAL ISCHEMIA-REPERFUSION: INVOLVED MECHANISMS**

Luisa Fernanda Gonzalez Arbelaez (1), Alejandro Ciocci Pardo (1), Juliana Fantinelli (1), Benjamín Rojano (2), Guillermo R Schinella (3), Susana M Mosca (1)
(1) Dr Horacio E Cingolani¨ Cardiovascular Research Center; National University of La Plata (UNLP), (2) University of Colombia, Medellín, (3) Faculty of Medical Sciences (UNLP)

The aim of this study was to determine the effects of isoespintanol (2-isopropyl-3,6-dimethoxy-5-methylphenol, ISO), isolated compound from leaves of *Oxandra cf xylopioides*, on ischemia-reperfusion injury. Isolated rat hearts perfused by Langendorff system were assigned to the following groups: 1. Non-ischemic control: 110 min of perfusion; 2.- Ischemic control (IC): 30 min of global ischemia (GI) and 60 min of reperfusion (R); 3.- ISO: 30 µg/ml ISO was administered during the first 10 min of R. To examine the mechanisms involved other hearts were treated with L-NAME (NOS inhibitor) or wortmannin (Akt inhibitor) or chelerythrine (PKC inhibitor) 10 min before ischemia. Infarct size was determined by TTC staining. Systolic and diastolic function was assessed by left ventricular developed pressure (LVDP) and the left ventricular end diastolic pressure (LVEDP), respectively. Coronary resistance (CR) was calculated as perfusion pressure and coronary flow ratio. The expression of phosphorylated form of endothelial NOS, Akt and PKCε was also measured. ISO significantly decreased the infarct size detected in IC group (11 ± 2 % vs. 31.0 ± 1.5%, $p< 0.05$) and improved post-ischemic recovery of myocardial function (LVPD: 63 ± 7 % vs. 17 ± 3%; LVEDP: 25 ± 5 vs. 52 ± 7 mmHg, $p< 0.05$). In IC, the level of P-eNOS, P-Akt and P-PKCε decreased approximately 45 % and after ISO treatment increased it (approximately 35 %). The increase of CR observed in IC group was significantly attenuated by ISO treatment (0.8 ± 0.2 vs. 3.3 ± 1 mmHg/ml x min^{-1}).The administration of all the inhibitors abolished the effects detected in ISO treated hearts.

The data show that acute treatment with ISO only at the onset of reperfusion decreased the infarct size and attenuated the post-ischemic myocardial contractility dysfunction and coronary resistance increase through Akt, PKCε and eNOS-dependent pathways.

(1427) **ETHOXYZOLAMIDE PROTECTS THE MYOCARDIUM AGAINST ISCHEMIA-REPERFUSION INJURY**

Alejandro Ciocci Pardo, Luisa Fernanda Gonzáles Arbeláez, Bernardo Victor Álvarez, Susana María Mosca
Centro de Investigaciones Cardiovasculares Dr. Horacio E. Cingolani

Carbonic anhydrase (CA) is responsible for catalyzing the reversible hydration reaction of carbon dioxide to form proton and HCO_3^-. The activation of CO_3H-dependent transporters during ischemia-reperfusion contributes to the Ca^{2+} overload and subsequent myocyte damage. Our objective was to determine the effects of CA inhibitor ethoxyzolamide on myocardial alterations produced by ischemia-reperfusion. Isolated rat hearts were submitted after 20 min of stabilization to the following protocols: 1.Non ischemic control (NIC): 90 min of perfusion; 2.Ischemic control (IC): 30 min of global ischemia (GI) and 60 min of reperfusion (R); 3.ETX: ethoxyzolamide 100 µM was administered during 10 min before ischemia and the initial 10 min of R. To examine the participation of p38MAPK, the protocols were repeated in presence of p38MAPK inhibitor SB202190 (10 µM) administered 10 min before ischemia. Infarct size (IS) was measured by TTC staining technique. Left ventricular developed pressure (LVDP), $+dP/dt_{max}$, left ventricular end diastolic pressure (LVEDP) and $-dP/dt_{max}$ served to assess myocardial function. The p38MAPK expression was measured. ETX decreased the IS (12.0 ± 0.4 % vs. 32 ± 2 % in IC, $p < 0.05$) and improved postischemic recovery of myocardial function. At the end of R, LVDP was 62 ± 3 % vs. 15 ± 4 %; $+dP/dt_{max}$: 62 ± 4 % vs. 19 ± 5 %; LVEDP: 36 ± 5 vs. 52 ± 5 mmHg; $-dP/dt_{max}$: 60 ± 5 % vs. 17 ± 5 %, $p < 0.05$). The p38MAPK level increased after ETX treatment (153 ± 9 % vs. 74 ± 8 %, $p < 0.05$). SB attenuated the effects detected by ETX.

The present data demonstrate that CA inhibitor ETX attenuates the post-ischemic myocardial dysfunction and decreases the cell death through p38MAPK-dependent pathways and suggest that an attenuation of Ca^{2+} overload could be the responsible mechanism.

(1526) **FIRST AND SECOND WINDOW OF PROTECTION OF PRE-ISCHEMIC VAGAL STIMULATION ON MYOCARDIAL INFARCTION IN MICE**

Jazmín Kelly (1) Nahuel Méndez Diodati (1), Eduardo Bernatené (1), Verena Franco Riveros (1), Verónica Casanova (2), Bruno Buchholz (1), Ricardo J. Gelpi (1)
(1) Universidad de Buenos Aires. Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET). Instituto de Bioquímica y Medicina Molecular (IBIMOL). Facultad de Medicina. Buenos Aires, Argentina. (2) Universidad de Buenos Aires. Facultad de Ciencias Veterinarias. Buenos Aires, Argentina

We have previously proven that vagal stimulation (VS) decreases infarct size (IS) when applied before ischemia, thus mimicking classic preconditioning. Our objective was to study the chronology and mechanisms of the protective effect of VS, and to assess whether the protection is comprised of a first and second window. Mice were randomly assigned to different protocols (n=5-7 per group). The control group had 30 min of regional myocardial ischemia and 2 h of reperfusion (I/R). The other groups consisted of 10 min of pre-ischemic VS (pVS) and different times of recovery between VS and I/R protocol: 5 min, 3-6-12-24-48-72-96 h. The 5 min, 3 h and 72 h groups were redone to administer a muscarinic receptor inhibitor (atropine). pVS-5min and pVS-72h were given a mitochondrial K+ ATP channel blocker (5-HD) and a nitric oxide synthase inhibitor (L-NAME). All animals were catheterized to measure ventricular function. Hearts were dyed with Evans Blue and incubated in TTC to measure IS.

pVS-5min had smaller IS in comparison to I/R (44±3% and 57±2%, respectively; p<0.05). pVS-3hs and pVS-6hs had a deeper IS reduction (34±3% and 34±3%, respectively; p<0.05 vs pVS-5min). Cardioprotection was lost at 12, 24 and 48 h post-VS (56±4%, 53±2%, 56±2%, respectively; p=NS vs I/R). Later at 72 h post-VS, cardioprotection reappeared (42±4%; p<0.05 vs pVS-48h) but was lost at 96 h post-VS (56±3%; p=NS vs I/R). The IS-reducing effect of pVS-5min, 3 and 72 h was abolished by atropine (56±2%, 56±3% and 56±3%; p=NS vs I/R), 5-HD in pVS-5min and 72 h (55±2% and 62±5%, p=NS vs I/R) and L-NAME in pVS-5min and pVS-72h (56±3% and 57±2%, p=NS vs I/R). In conclusion, VS has two protection windows similar to classic preconditioning. The first window lasts 6 h and the second window appears at 72 h and is lost at 96 h. The mechanisms underlying the cardioprotective effect include muscarinic receptors, mitochondrial K+ ATP channels and nitric oxide synthase.

(741) **RELATIONSHIP BETWEEN CARDIOPROTECTIVE EFFECTS OF ROSUVASTATIN (R) AND INACTIVATION OF GSK3B IN RAT HEARTS SUBJECTED TO ISCHEMIA-REPERFUSION.**

Debora Velez, Victoria Mestre Cordero, Juliana Perego, Romina Hermann, Marianela Penida, María Gabriela Marina Prendes

Cátedra de Fisiología, Facultad de Farmacia y Bioquímica. UBA; IQUIMEFA-CONICET.

Previously in our laboratory we could establish that the administration of R in hearts subjected to ischemia-reperfusion (I-RP) generated direct cardioprotective effects. These results were accompanied by increased activation of Akt, attenuation of the opening of the Mitochondrial Permeability Transition Pore (MPTP) and preservation of mitochondrial structure. The goal of the present work was to determine the relationship between these events, phosphorylation of GSK3β and the metabolic environment in Langendorff perfused rat hearts subject to I-RP. Wistar female rats (250-300g body weight) fed ad libitum were used. R (3uM) and wortmannin (W 100nM), Akt inhibitor, were added 10 and 15 min before global I respectively. Hearts were subjected to 25 min of I and 60 min of RP. Tissue samples were taken at the end of stabilization and ischemia to determinate lactic acid and glycogen content. The activation profile of GSK3β was studied by western blot taking into account GSK3β-P/GSK3β-T.ANOVA (n=6/group)

Lactic acid content were meaningfully lower in those hearts treated with R (μmoles/g dw): C (control): 146,28±6,60**; R: 56,68±6.77; W: 65,31±5,22; R+W: 61,35±4,10 (**p<0,01 against all groups), although paradoxically glycogen content was similar between hearts treated with R and group C μg/100 mg dw) C: 148,76±32,86*; R: 120,73±25,49*; W: 288,39±21,77; R+W: 324,64±34,75) (*p<0,05 vs W y R+W). Available glucose could be entering the pentose pathway, generating a metabolic environment more beneficial to those hearts subject to IS-RP. Likewise GSK3β presented major phosphorylation in the R group (p<0,05 vs C, W,R+W).

Our results suggest that the cardioprotection exerted by rosuvastatin could be mediated, at least in part, by the phosphorylation of GSK3β, which together with the appropriate metabolic environment could attenuate the opening of the MPTP, promoting alternatives that allow myocyte to face I-RP injury.

Key words: Rosuvastatin, ischemia, cardioprotection, MPTP, GSK3β.

(915) **RELEVANCE OF ANATOMICAL SITE TO ACTIVATE REMOTE ISCHEMIC PRECONDITIONING.**

Diamela Tatiana Paez (1), Martin Donato (1), Carla Greco (2), Ricardo J Gelpi (1)

(1) Instituto de Fisiopatología Cardiovascular, Facultad de Medicina, Universidad de Buenos Aires, (2) Facultad de Ciencias Veterinarias, Universidad de Buenos Aires.

Introduction: Remote ischemic preconditioning (rIPC) reduces myocardial infarct size in different animal species, however, in humans the results are contradictory, probably because it has not been considered the anatomical site of stimulation as a variable that could influence the results.

Objective: The aim was evaluate the effects of rIPC on infarct size, considering the optimal anatomical site (arm or thigh) to achieve the myocardial protection. A second objective was to describe some of the pathways involved in the rIPC protection.

Methods: Isolated rat hearts were subjected to 30 min of global ischemia followed by 60 min of reperfusion (I/R). In additional groups, a rIPC protocol of 3 cycles of I/R were performed. This protocol was applied to the right and left femoral artery and in the right and left axillary arteries. We studied the involvement of a vagal neural pathway by performing a bilateral cervical vagotomy prior to the rIPC protocol. The humoral pathway was evaluated by administering DPCPX (adenosine A_1 receptor blocker). Infarct size was measured using triphenyltetrazolium chloride staining.

Results: rIPC performed in the left and right femoral artery significantly decreased infarct size (35,6±1,2 and 30,08±5,2 %, p< 0,05 vs I/R) and this effect was abolished by bilateral vagotomy. In the same way, rIPC performed in the left axillary artery significantly decreased infarct size (27±4,4 %, P< 0,05 vs I/R). This effect was not abolished by bilateral vagotomy. As we mentioned, in order to evaluate the humoral pathway, we administered DPCPX, which completely abolished the beneficial effect of rIPC. Interestingly, rIPC performed in the right axillary artery has not effects on I/R injury.

Conclusions: rIPc performed on hind limb reduces infarct size by a parasympathetic vagal pathway. However, in the left arm, rIPC induced protection by activation of adenosine A_1 receptors; suggesting the participation of an humoral pathway.

Keywords: Ischemic Preconditioning - Myocardial Infarction - Myocardial Protection

(756) **ROLE OF AMP-ACTIVATED PROTEIN KINASE (AMPK) IN MYOCARDIAL ISCHEMIA-REPERFUSION (Is-Rs): DIFFERENTIAL EFFECTS DEPENDING ON THE ENERGETIC SUBSTRATES AVAILABLE.**

Abstract: AMPK functions as a cellular fuel gauge, being activated to reestablish energy homeostasis at a cell-autonomous level. The role of AMPK in myocardial Is-Rs remains uncertain.

In this study, we explored the effects of the pharmacological inhibition of AMPK by Compound C (CC; 10 μM) in isolated rat left atria subjected to 75 min Is-75 min Rs. Since levels of fatty acids are elevated in most clinical situations of Is-Rs, the influence of palmitate was also studied. For this aim, atria were incubated in Krebs–Ringer containing 10 mM glucose (G) or G and 1,2 mM palmitate (P), 95% O_2–5% CO_2, pH 7,4. For Is, the incubation medium contained 10 mM 2-deoxy-D-glucose, 95% N_2 – 5% CO_2, pH 6,8. ANOVA, n=8.

Results showed a significant increase in AMPK endogenous activation during Is, remaining activated during Rs. CC prevented it. During Is, peak contracture developed earlier in the atria stabilized with P. In this condition, CC increased maximum contracture. These results were consistent with changes in tissue ATP content. Lactate accumulation was reduced by P and even more by CC in both metabolic groups. At the end of Rs contractile reserve (CR) attenuation was more pronounced by P. CC showed dual effect, it increased CR attenuation in the presence of G, but reversed the harmful effect of P. These results were accompanied by similar changes in tissue ATP content, but the rate of mitochondrial ATP synthesis showed no significant differences between groups. PDH activity was reduced in the presence of P. CC reduced PDH activity in the atria incubated with G, but partially reverted P effect. CC also reduced autophagosome like structures and LC3-II/LC3-I ratio, an established indicator of autophagy, in both metabolic conditions. Cellular viability was not affected by P or CC.

The results support that intrinsic activation of AMPK has cardioprotective effects in the reperfused atria when G is the only available energy substrate, but results deleterious when P is also available.

(853) **ROLE OF AUTOPHAGY IN MYOCARDIAL ISCHEMIA-REPERFUSION (Is-Rs): INFLUENCE OF AVAILABLE ENERGY SUBSTRATES**

Romina Hermann (1), Federico Reznik (1), María de las Mercedes Fernández Pazos (1), Victoria Mestre Cordero (1), Débora Vélez (1), María Gabriela Marina Prendes (1), Alicia Varela (1)

(1) Cátedra de Fisiología, Facultad de Farmacia y Bioquímica, UBA. IQUIMEFA-CONICET.

Abstract: Autophagy is a prominent feature of myocardial Is-Rs. However, the functional significance is still unclear and controversial.

In this study, we explored effects of autophagy in isolated rat left atria subjected to 75 min Is-75 min Rs, when atria were incubated in the presence of 10 mM glucose (G) or G and 1,2 mM palmitate (P), as observed in most clinical situations of acute myocardial infarction, which are less well established. For this aim, the effects of the autophagy inhibitor 3-methyladenine (3-MA, 5 mM) were assessed. ANOVA, n=8.

Results showed a significant enhance in the LC3-II/LC3-I ratio, an established indicator of autophagy, during Rs, which was achieved more slowly in the presence of P. These results were accompanied by a concomitant decrease of p62, a specific substrate degraded through the autophagy-lysosomal pathway, in both groups. 3-MA prevented LC3 ratio increase and produced p62 accumulation in both metabolic conditions. Electron micrographs showed autophagosome like structures during Rs, which were absent in the presence of 3-MA. Autophagy inhibition was accompanied by a deterioration of mitochondrial morphology and function, although these results were not affected by P. ATP content recovery during Rs was reduced by P and 3-MA in both metabolic conditions, being this result consistent with attenuation in contractile reserve at the end of Rs. In the presence of 3-MA, either in the atria incubated with G or P, spontaneous tachyarrhythmias (270-300 contractions per min) were observed throughout Rs, which were attenuated by the inner membrane anion channel blocker PK11195, suggesting an involvement of mitochondria in the 3-MA-induced arrhythmias. These results were not affected by P.

Present results suggest that autophagy is induced during reperfusion developing cardioprotective effects. P present at high concentrations as an exogenous energy substrate, would not have significant effects on this process in the ischemic-reperfused myocardium.

Keywords: Autophagy, ischemia, reperfusion, myocardium, palmitate

(612) **ROLE OF mKATP AND EFFECTS OF ORAL ADMINISTRATION OF CARVEDILOL TO HYPERTHYROID RATS WITH STUNNING DUE TO ISCHEMIA-REPERFUSION**

María Inés Ragone, María Lara Lazarte, Alicia Elvira Consolini

Catedra de Farmacología Farmacia UNLP. CONICET

Previously, we showed that hyperthyroidism (HpT) got worse the stunning induced by severe ischemia-reperfusion (I/R) in rat hearts with the opening of mPTP (SAFE 2014). Morever, we found that the perfusion with 0.03 μM carvedilol (Carv) before I/R protected euthyroid (EuT) but not HpT hearts from stunning (SAFE 2015). The aims of this work were to evaluate the role of mKATP and the effects of oral administration of Carv in HpT and EuT hearts exposed to stunning without infarct. HpT was induced by daily SC injection of 20 µg.kg^{-1} T3 during 15 days. Isolated hearts were perfused inside a calorimeter at 37°C to measure left ventricular pressure (LVP, in mmHg) and total heat rate (Ht, in mW.g^{-1}) during exposition to severe I/R (30 minI/45min R). In order to evaluate the role of mKATP, HpT and EuT hearts were pretreated with 30 μM diazoxide (Dzx, mKATP opener). In HpT, Dzx increased the postischemic contractile recovery (PICR, 90.7±10.5 vs 24.7±3.8% in non treated: C-HpT, n=6-5, p<0.05), the total muscle economy (Eco=P/Ht, 5.2 ± 0.5 vs 1.6 ± 0.2 mmHg.g.mW^{-1} in C-HpT) and prevented the diastolic contracture. In EuT, Dzx produced the same effects than in HpT (n=5-6). Carv was given in drinking water (20 mg/kg/day) to HpT and EuT rats during 1 weak before the I/R experiment. In HpT, Carv improved the PICR up to 68.3 ± 10.8 % of initial pressure (Pi), at the end of R (p< 0.05 vs 23.5 ± 3.4 % of Pi in C-HpT, n=4-5) and Eco up to 4.3 ± 0.2 mmHg.g.mW^{-1} (p<0.05 vs 1.6 ±0.2 in C-HpT) while prevented the diastolic contracture. In EuT, Carv increased PICR (55.4 ±17.2 vs 11.6 ± 4.7 % of Pi in non treated: C-EuT, n=4-5; p <0.05), without changing Eco nor diastolic tone. Results suggest that: a) The mKATP opening prevents the stunning in HpT and EuT hearts; b) Oral administration of Carv prevents dysfunction due to severe I/R more in HpT than in EuT. *Grant: UNLP X-795*.

(1067) **THE CARDIOPROTECTION CONFERRED BY THIOREDOXIN-1 IN ISCHEMIC POSTCONDITIONING IS ABOLISHED IN MIDDLE-AGED MICE.**

Virginia Perez (1), Verónica D´Annunzio (1), Tamara Zaobornyj (2), Anabella Gomez (1), Tamara Mazo (1), Verónica Casanova (3), Eliana Cicale (3), Ricardo J. Gelpi (1)

(1) IBIMOL, Sede Facultad de Medicina, (2) IBIMOL, Sede Facultad de Farmacia y Bioquímica, (3) Bioterio Central, Facultad de Ciencias Veterinarias, UBA

Thioredoxin-1 (Trx1) maintains the cellular redox status and decreases the infarct size in ischemia/reperfusion injury (I/R). However, it is not fully understood the role of Trx1 in ischemic postconditioning (PostC) in young and aged mice. The aim was to study if Trx1 is involved in the PostC cardioprotection mechanism and if the age can modify this. Wild type mice hearts (Wt), transgenic mice hearts overexpressing Trx1, and a dominant negative (DN-Trx1) mutant (C32S/C35S) of Trx1 were used, mice were divided in young group (4 month) and middle-aged group (12 month). The mice hearts were subjected to 30 min of I and 120 of R (Langendorff technique) (I/R group). In the PostC group, after I, a protocol of 6 cycles of R/I was performed. The assessment of the infarct size was performed using TTC. Also, it was measure hidrogen peroxide (H_2O_2) production, protein nitration, Trx1 activity and expression and pAkt and pGSK3β expression (western blot). Data are expressed as mean±SEM and p<0.05 was considered statistically significant. n= 6 each group.

Previously, we showed that Trx1 is involved in cardioprotection conferred by PostC in young mice. Then we performed the same groups but in middle-aged mice and the cardioprotection was abolished in groups with PostC (Wt-PostC: 53.13±4.58% vs Wt-I/R: 51.75±2.64%; DN-Trx1-PostC: 51.17±5.04% vs DN-Trx1-I/R: 56.57±4.24% and Trx1-PostC: 51.50±3.94% vs Trx1-I/R: 52.88±3.07%). This infarct size behavior was accompanied by a significant lack of survival proteins phosphorylation (Akt and GSK3β) and significant changes in Trx1 expression (in Wt group). Trx1 activity was significantly disminished, H_2O_2 production and protein nitration were significantly increased in all middle-aged groups. Our results showed that Trx1 plays a key role in the PostC protection mechanism in young mice but in middle-aged mice this cardioprotective mechanism was abolished.

(1100) **THE ROLE OF THIOREDOXIN 1 IN THE ISCHEMIC POSTCONDITIONING ON MICE FED HIGH FAT DIET**

Tamara Mazo (1), Anabella Gomez (1), Tamara Zaobornyj (2), Virginia Perez (1), Eliana Cicale (3), Verónica Casanova (3), Magali Barchuk (4), Gabriela Berg (4), Verónica D´Annunzio (1), Ricardo J Gelpi (1)

(1) IBIMOL, Sede Facultad de Medicina, (2) IBIMOL, Sede Facultad de Farmacia y Bioquímica, (3) Bioterio Central. Facultad de Veterinaria. UBA, (4) Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Instituto de Fisiopatología y Bioquímica Clínica (INFIBIOC). Buenos Aires, Argentina.

Thioredoxin-1 (Trx1) has cardioprotective effects against ischemia/reperfusion (I/R) injury, and participates in mechanisms mediating ischemic postconditioning (PostC). It remains unclear whether the

PostC protective effects are exerted during initial stages of atherosclerotic disease by altering *Trx1* expression. The objective of this study was to generate a murine high-fat diet (HFD) fed model that developed phenotypes consistent with early-stage atherosclerosis, and then evaluate increased oxidative stress, altered mitochondrial bioenergetics and *Trx1* expression in the HFD model. Ultimately, the model was used to determine whether HFD exposure abolished the cardioprotection conferred by PostC. C57/BL6 mice were fed with control diet (CD) or HFD for 12 weeks. Mice isolated hearts was subjected to 30 min of ischemia and 120 min of reperfusion (I/R group). For PostC subjects, after ischemia, six cycles were performed of reperfusion/ischemia (10 sec respectively, per cycle) at the onset of reperfusion. Data are expressed as mean±SEM and $p<0.05$ was considered statistically significant. n= 6 each group. In CD group, the Post had reduced infarct size (CD-I/R: 52.14±2.8 vs. CD-PostC: 36.58±1.8, $P<0.05$). This cardioprotection was abolished in HFD-exposed subjects. HFD increased production of hydrogen peroxide and *Trx1* expression. State 3 mitochondrial oxygen consumption in basal conditions was 24% decreased in HFD-exposed subjects. PostC restored state 3 values in controls more completely than in HFD-exposed subjects. Redox states and mitochondrial bioenergetics were altered in HFD-exposed subjects, leading to increased *Trx1* levels. These changes were accompanied by failed cardioprotection in HFD-subjects that is normally conferred by PostC. In conclusion, this study demonstrated the novel finding that alterations in redox state were enough to abolished cardioprotective mechanisms, such as those induced by PostC.

(2) CIBICI-CONICET, Facultad de Ciencias Químicas, Universidad Nacional de Córdoba, Argentina. (3) Instituto de Biología Celular, Facultad de Ciencias Médicas, Universidad Nacional de Córdoba, Argentina.

Maternal and fetal ghrelin (Ghr) concentrations normally increase during pregnancy suggesting that this hormone exerts important roles on early gestational events. Moreover, some available evidence indicates that Ghr has immunomodulatory properties.

Herein, we aimed to evaluate the effects of Ghr and its pharmacological blockade (antagonist treatment) on implantation events using an already validated mouse model of Ghr misbalance during pregnancy.

Albino Swiss (N:NIH) mice dams were s.c. injected with Ghr (4 nmol/animal/day), an antagonist [Ant: (D-Lys3)GHRP-6; 6 nmol/animal/day] or vehicle (C: saline solution) from day 3 to 8 of gestation. Dams were euthanized at day 8, uteri exposed and analyzed macro and microscopically. The percentages of normal or atrophied fetuses and the number of implantation or resorbtion sites were recorded. In addition, the expression levels of VEGF, MMP9, GM-CSF, IL-10, IL-17 and IL-6 in uterine tissue was analyzed by qPCR. Plasma progesterone (P_4) concentrations were quantified by ELISA. Results was analyzed by ANOVA.

The blockade of Ghrelin (Ant) increased the number of resorbtion sites (C=0.5±0.5, Ghr=1.2±0.4, Ant=3.7±0.5; $p<0.05$) and the percentage of atrophied fetuses (C=4.4±4.0, Ghr=8.9±3.6, Ant=30.2±4.0; $p<0.05$). However, no significant differences were observed in the uterine expression levels of VEGF, MMP9, GM-CSF, IL-10, IL-17 or IL-6 among groups (VEGF=2.72±0.50, MMP9=7.57±0.51, GM CSF=8.73±0.53, IL-10=8.14±0.63; IL-17=8.38±0.85 and IL-6=4.58±0.71; n=14, $p>0.05$). Moreover, plasma P_4 concentrations did not show any significant differences among experimental groups under study ($p>0.05$).

Up to date, our results suggest that Ghr misbalance affects fertility by impairing embryo development not related to immune cytokine alterations at the maternal interface or by altering systemic P_4 levels. Additional experiments are being carried out in order to unveil the putative underlying mechanisms of these effects.

Keywords: ghrelin; implantation; inflammation; angiogenesis; fertility.

(980) **PROINFLAMMATORY RESPONSE OF HUMAN ENDOMETRIAL EPITHELIAL CELLS TO *Brucella abortus* INFECTION**

Andrea G. Fernández (1), Mariana C. Ferrero (1), Andrea Ritter (2), Florencia Muñoz González (1), Iván Alonso Paiva (1), Alberto C. Fossati (1), Pablo C. Baldi (1)
(1) IDEHU, Facultad de Farmacia y Bioquímica, UBA, Buenos Aires, Argentina, (2) Department of Obstetrics and Gynecology (Endocrinology Laboratory), University Hospital Freiburg, Freiburg, Germany

Brucella induces abortion in humans and animals. Therefore, the interaction between uterine cells and *Brucella* is important for understanding the pathogenesis of this disease. In this work, we evaluate the inflammatory response (chemokine and metalloproteinases) and the expression of hormonal receptors and various microRNA related to infection or inflammation processes in the human endometrial epithelial cell line Ishikawa, after infection with *B. abortus* 2308 or stimulation with conditioned medium (CM) from infected human phagocytes or trophoblasts. The Ishikawa cells, the monocytic cell line THP-1, the trophoblastic cell line Swan-71 and monocytes and neutrophils isolated from peripheral blood were infected with *B. abortus* for 2 h. After treatment with gentamicin, supernatants were collected at 24 and/or 48 h. Here we show that *B. abortus* invades and replicates in Ishikawa cells without inducing an increase in interleukin 8 (IL-8) or monocyte chemoattractant protein 1 (MCP-1) secretion. However, the stimulation of Ishikawa cells for 48 h with CM from *B. abortus*-infected THP-1 cells, primary monocytes or Swan-71 cells induces a significant increase of IL-8 and MCP-1 as compared to stimulation with CM from non-infected cells ($p<0.01$). The stimulation of Ishikawa cells with CM from infected neutrophils or trophoblasts increases the activity of metalloproteinase 9 (MMP-9) ($p<0.05$) but does not modify the expression of progesterone, estrogen or glucocorticoid receptors, neither the expression of the microRNAs tested (miR-16, miR-21, miR-23a, miR-34a, miR-125b, miR-126, miR-155, miR-200a, miR-222, miR-223, let-7a and let-7c). These results suggest that human endometrial epithelial cell may provide a local inflammatory environment during *B. abortus* infection through interactions with infected phagocytes and trophoblasts, potentially contributing to the pregnancy complications of brucellosis.

Keywords: *Brucella abortus*, abortion, endometrial epithelial cell, inflammation.

Daniela Madanes, Bárbara Mc Cormack, Carla Noemí Olivares, Mariela Andrea Bolitas, Luciana Ferella, Gabriela Meresman, Rosa Inés Barañao, Analía Gabriela Ricci
Instituto de Biología y Medicina Experimental (Ibyme-CONICET)

It is known from our previous studies that resveratrol (RES) and epigallocatechin gallate (EGCG), two natural polyphenols with well-known anticarcinogenic properties, have a strong antiproliferative and proapoptotic activity both in-vivo and in-vitro in experimental endometriosis. Moreover, we recently showed the participation of PI3K/AKT pathway in endometriosis, both in patients and experimental models. The aim to this work was to study the in-vitro effect of these compounds on aromatase and estrogen receptor α expression and to evaluate the impact of RES on endometrial cells proliferation induced by E_2. Human endometrial epithelial (ECC-1) and stromal (T-HESC) cell lines were cultured according to standard protocols and were stimulated with different doses of RES (50

and 100μM) or EGCG (20 and 40μM) for 24h. Cell proliferation was assessed using the WST-1 reduction kit, in presence or absence of E_2 and/or the estrogen receptor antagonist ICI 182,780. Levels of aromatase and estrogen receptor α expression were assessed by Western Blot. Both doses of RES inhibited aromatase expression ($p<0.01$) and 100μM RES reduced total estrogen receptor α levels ($p<0.05$) in both cell lines. In addition we found that both RES doses were able to inhibit the ECC-1 proliferation, even that induced by E_2 ($p<0.05$). Preliminary results on ECC-1 show that RES could be using more than one pathway, including that triggered by estrogen receptor. EGCG reduced the aromatase expression in T-HESC ($p<0.01$) as well as in ECC-1 ($p<0.05$) cell line. Besides, EGCG diminished total estrogen receptor α levels ($p<0.05$) in both cell lines. These results, taken together with our previously published ones, encourage us to investigate these compounds as novel strategies to treat endometriosis. More studies need to be undertaken to finally understand if RES and EGCG exert their inhibitory action through estrogen pathway inhibition which may represent an accurate therapeutic for an estrogen-dependent disease.

Keywords: Endometriosis, resveratrol, EGCG, aromatase, estrogen.

(1604) **STUDY OF THE IMMUNE RESPONSE ASSOCIATED WITH GENITAL INFECTIONS AND ITS RELATIONSHIP WITH INFERTILITY**

Romina Cecilia Russi (1), Paula Julieta Cepeda (1), Evelin Cáceres (2), Carla Bernasconi (2), María Ines García (1), German Henrich (2), Carolina Veaute (1)

(1) Laboratorio de Inmunología Básica, Facultad de Bioquímica y Ciencias Biológicas, Universidad Nacional del Litoral. (2) Laboratorio Central del Hospital JB Iturraspe, Santa Fe, Argentina.

Chlamydia trachomatis (Ct), Mycoplasma hominis (Mh) and *Ureaplasma urealyticum (Uu)* are usually associated with infertility. Our aim was to study immunological factors induced by genital infections as a potential cause of infertility. Antisperm antibodies (ASA) were analyzed by ELISA and cytokines and master transcription factor expression were quantified by RT-qPCR using the ΔΔCt comparative method. Sperm parameters were analyzed by WHO recommendations. Vaginal washing were collected from 59 females, Infertile With Infection (IWI-f), Infertile Without Infection (IWoI-f), Fertile Without Infection (FWoI-f) and semen from 27 Infertile male With (IWI-m) and Without infection (IWoI-m). Categorical variables were analyzed by Fisher's Exact test, $P<0.05$ was considered statistically significant. We found a significant association between the type of infection and the patient's sex, for IWI-f with *Mh* and IWI-m with *Uu* infection. No significant difference in sperm parameters between IWoI-m and IWI-m were found. ASA analysis showed no correlation with infertility or infection. Cytokine expression exhibited a significant upregulation in IWoI-f compared to FWoI-f, for IL-6, IL-10, IL-17A, RORγt, FOXp3 and Tbet (Relative Expression [RE]: 5.9, 4.7, 4.4, 12.2, 4.9, 8.7; respectively). In IWI-f with *Mh*, IL-10 was significantly increased (RE: 3.2), while with *Uu,* INFγ, RORγt, FOXp3 were increased, versus FWoI-f (RE: 7.8, 10.7, 12.2, respectively). In IWI-f, the *Mh* and *Ct* were associated with a decrease for IL-17A, RORγt and Tbet, which were significant for *Mh* (RE: 0.25, 0.23, 0.13, respectively) but not for *Ct,* versus IWoI-f. In IWI-m with *Uu* IL-8 was significantly augmented (RE: 8.5) versus IWoI-m. Infertility is associated with an upregulation of several proinflammatory cytokines, in the absence of infection. Alterations in cytokine expression were observed in infertile patients with *Mh* and *Uu* infection. Cytokine disturbance may be associated with infertility.

Keywords: infertility, antisperm antibodies, cytokines, master transcription factors, genital infection

(1524) **THE HYALURONAN SYNTHESIS *INHIBITOR* 4-METHYLUMBELLIFERONE (4MU) EFFECT ON ENDOMETRIOSIS (EDT)**

Carla Noemi Olivares (1), Mariela Andrea Bilotas (2), Analía Gabriela Ricci (2), Laura Daniela Alaniz (3), Daniela Madanes (2), Luciana Ferella (1), Emilia Soledad Bogni (1), Inés Stella (4), Rosa Inés Barañao (2), Gabriela Fabiana Meresman (1)

(1) Laboratorio de Fisiopatología Endometrial, Instituto de Biología y Medicina Experimental. (2) Laboratorio de Inmunología de la Reproducción, Instituto de Biología y Medicina Experimental. (3) Laboratorio de Microambiente Tumoral, CIBA, CIT NOBA (UNNOBA-CONICET). (4) Hospital Municipal Bernardino Rivadavia.

It is known from previous studies that 4MU has antiproliferative and antiangiogenic properties. We evaluated the effect of 4MU in EDT models. Stromal T-HESC and epithelial ECC-1 endometrial cell lines, were treated with different doses of 4MU (ranging 0-4mM) and cell proliferation (CP) by the WST-1 assay was evaluated. Mice were surgically induced with EDT and treated orally with 4MU during 28 days. Six groups were included in the in vivo experiment, two different time points for initiating the treatment (2 and 15 days) and two different doses of 4MU (80 and 200mg/kg) with the appropriate vehicle control groups. The number and size of developed lesions were evaluated, as well as vascularization, CP, infiltrating lymphocytes and collagen depot within the endometriotic lesions. CP of T-HESC was significantly inhibited with 2 and 4mM 4MU ($p<0.05$); preliminar results on ECC-1 show that all concentrations of 4MU tested inhibit CP. In vivo, there was a significant reduction in the number of developed lesions in the 200mg/kg group starting treatment at day 2 ($p<0.05$ vs. day 15) and the size of these lesions was significantly reduced too ($p<0.05$ vs. control). Vascularization, evaluated by von Willebrand Factor immunohistochemistry (IHC), did not differ after treatment. CP of epithelial or stromal endometriotic cells was unaltered as seen after PCNA IHC was performed. Lesion-infiltrating lymphocytes were homogenous along all treatment groups as well as collagen depot; demonstrated by hematoxilin eosin and Masson´s trichrome staining, respectively. In vivo, 4MU did not demonstrate to be an efficacious treatment option, although further studies are being held to elucidate what mechanisms have been altered that are reflected in an overall lesser lesion size and number for the 200mg/kg dose at day 2, while in vitro results are promising. Many more studies need to be undertaken to finally understand if 4MU can be thought of as an alternative treatment option in EDT.

Key words: endometriosis, cell proliferation, angiogenesis, hyaluronan inhibition

(704) **ANALYSIS OF *Ureaplasma urealyticum*, *Mycoplasma hominis*, AND *Chlamydia trachomatis* INFECTION OF THE MALE GENITOURINARY TRACT AND SEMEN QUALITY PARAMETERS**

Daniela A. Paira (1), Andrea Tissera (2), Rosa Molina (2), Florencia C. Salazar (1), Virginia E. Rivero (1), Rubén D. Motrich (1)

(1) CIBICI-CONICET, Facultad de Ciencias Químicas, Universidad Nacional de Córdoba, Argentina. (2) Laboratorio de Andrología y Reproducción (LAR), Córdoba, Argentina.

Male factors account for up to 50% of infertility cases, and infection in the genitourinary tract may play a contributing role in up to 15% of male infertility. In fact, several microorganisms have been proposed to play a pathogenic role in both genital infections and male infertility. Leukocytospermia is a well-known indicator of male urogenital infection or inflammation that can be deleterious to sperm.

This study aimed to analyze leukocytospermia and standard semen quality parameters from infected and non-infected young adult men. A total of 930 semen specimens were collected by masturbation from men attending to the Andrology clinic in a period of seven years. Analysis of *Ureaplasma urealyticum, Mycoplasma hominis,* and *Chlamydia trachomatis* infection were performed by molecular or culture methods. Semen analysis was assessed according to the World Health Organization guidelines. Non-parametric tests were used for statistical analysis.

Analysis of standard of semen quality parameters between non-infected and infected men showed that the presence of *Ureaplasma urealyticum* infection was associated with significantly increased semen leukocyte counts ($p<0.05$), low sperm concentration ($p<0.0001$) and abnormal sperm morphology ($p<0.0001$). On the other hand, the presence of *Mycoplasma hominis* or *Chlamydia trachomatis* in-

fection did not associate with leukocytospermia (p>0.05). However, the presence of the latter both infections were associated with significantly decreased sperm viability (p<0.008) and normal morphology (p<0.004) levels.

Our results revealed that although the presence of any of the infections analyzed herein seemed to negatively influence semen quality, *Ureaplasma urealyticum* infection increased seminal leukocyte concentrations and decreased sperm quality parameters. In conclusion, these data indicate once more that male genital tract infections should be routinely screened in the clinic when assessing potential causes of infertility.

Keywords: male infertility, semen quality, infection, leukocytospermia, inflammation.

(701) **CERAMIDE-1-PHOSPHATE (C1P): SHIELDING OVARIAN FERTILITY FROM CHEMOTHERAPY-INDUCED DAMAGE IN A MICE MODEL OF PREMATURE OVARIAN FAILURE (POF)**

Natalia Pascuali (1), Leopoldina Scotti (1), Gonzalo Oubiña (1), Mariana Di Pietro (1), Maria May (2), Marta Tesone (1), Dalhia Abramovich (1), Fernanda Parborell (1)
(1) Instituto de Biología y Medicina Experimental (IByME-CONICET), Buenos Aires, Argentina. (2) Instituto de Investigaciones Farmacológicas (ININFA-UBA-CONICET), Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, Buenos Aires, Argentina.

Cancer-directed therapies cause accelerated loss of ovarian reserve leading to POF. As sphingolipid C1P can regulate angiogenesis and apoptosis, we propose it can modulate ovarian function affected by cyclophosphamide (Cy).

8-week-old mice (C57BL/6 x Balb/c F1) were given either an i.p. injection of Cy (75 mg/kg) or saline solution only (control). Control and Cy mice underwent sham surgery (intrabursal injection of saline solution), while Cy+C1P mice received intrabursa 5 *µ*l C1P (1 mM). After 2 weeks, mice were euthanized for ovary and uterus collection for histology, IHC and western blot studies. ANOVA followed by Tukey test were performed when needed.

We had previously observed that Cy decreases primordial, primary and preantral follicles, while increasing atretic follicles compared to control mice, while in Cy+C1P mice, ovaries recover control numbers of all follicular types. We have now found evidence that Cy increases protein expression of pro-apoptotic BAX (p<0.01) and decreases anti-apoptotic BCLX-L compared to control ovaries (p<0.01), while these protein levels in Cy+C1P mice are no different from control. The apoptotic index (TUNEL-positive follicles/total follicles) in preantral and early antral stages was higher in Cy mice compared to control (p<0.001 and p<0.01), while C1P protected ovaries from Cy-induced apoptosis.

Cy also caused thickening and hyalinization of vascular walls, especially in cortical stromal vessels, which was less evident in Cy+C1P ovaries, with fewer endothelial alterations. Cy-treated ovaries showed discontinuous distribution of α-SMA-positive cells (peri-endothelial marker) around blood vessels. C1P partially prevented this, increasing α-SMA-positive vessel coverage. By H&E, Cy-treated mice showed endometrial alterations in both epithelial and stromal compartments compared to control, while C1P protected endometrial quality.

Thus, C1P administration prior to Cy might be a promising fertility preservation strategy in cancer patients.

(667) **DIETARY OLIVE OIL IMPROVES SEXUAL GLANDS HISTOLOGICAL ALTERATIONS AND TESTICULAR CHOLESTEROL METABOLISM IN HYPERCHOLESTEROLEMIC RABBITS**

Miguel Walter Fornes, Tania Saez, Abi Funes, Regina Colombo, Layla Simón
IHEM - Conicet - UNCuyo

The relationship between hypercholesterolemia and reduced male fertility has been reported previously. Hypercholesterolemic rabbits (HCR) were associated with deleterious changes in semen and sperm cells: seminal volume was decreased and sperm membrane was overloaded with cholesterol. Olive Oil (OO) supplementation (7% v/p) improved semen parameters affected by high fat diet. A decrease in seminal volume could be explained by alteration in accessory glands coupled to male tract, as prostate and seminal vesicle. The increase in membrane cholesterol could be due to changes in intracellular metabolism of this lipid. New Zealand White rabbits were fed commercial rabbit pellet (normocholesterolemic rabbits: NCR), plus 14% bovine grease (HCR) or 7% bovine grease plus OO (7%) (½HCR + ½OO). Prostate and seminal vesicle were processed for light microscopy and morphometry. In HCR, prostate epithelium height and proprostate villi length significant decreased (p<0.05) compared to NCR. Only proprostate villi lenght was recovered in ½HCR + ½OO. Mucose high in seminal vesicle decreased (p<0.05) in HCR but did not significantly improve with OO addition. Therefore, cholesterol intake affects mainly proprostate villi, prostate epithelium and seminal vesicle mucosa. Within molecular regulation, SREBP (Sterol- Regulatory-Binding-Protein) proteins are essential for biogenesis and membrane homeostasis. At 3 months of diet, SREBP2 mRNA expression did not show significant changes in testis, between NCR and HCR. In contrast, protein expression showed a significant increase in HCR testis. SREBP target molecules followed the same pattern. ½HCR + ½OO showed a recovery in the expression of the mentioned proteins. Taken together, the deleterious impact on reproductive tissues found in HCR could be related to alterations in sex accessory glands as well as changes in metabolic status of testis. OO was able to improve the majority of altered parameters in dietary acquired hypercholesterolemia.

Abstract: Cocaine intake is associated with testicular toxicity and significant reproductive function impairment. Recent evidences suggest that cocaine administration in animal models can trigger non-genetic inheritance of addiction traits from father to offspring, affecting development and behavior. This paternal transmission was proposed to be mediated by the epigenetic reprogramming of testicular germ cells. In the present study, we measured epigenetic and functional markers in testis of adult mice treated with cocaine (Coc 10 mg/kg) compared to vehicle (Veh), in an intermittent binge protocol (3 i.p. injections, 1 h apart, one day on/off for 13 days). We have previously shown that this Coc administration protocol induced testicular germ cell loss together with increased ROS species (González et al., PLoS One. 2015 doi: 10.1371/journal.pone.0142713). Importantly, toxicity occurred in parallel with testicular dopaminergic system dysregulation: Coc induced increased tyrosine hydroxilase expression and dopamine receptors *Drd1* and *Drd2* downregulation. In the present study, we found that chronic Coc intake in mice disrupts testicular epigenetic homeostasis, increasing global histone 3 acetylation and decreasing HDAC1/2 deacetilases mRNA and protein expression (p<0.05). We also found decreased *Hdac3* and *Hdac8* mRNA expression (p<0.05). HDAC1/2 and histone 3 acetylated proteins were localized in Leydig cells and mainly in meiotic germ cells within the seminiferous tubules. We observed altered mRNA expression of DNA methylation markers like increased *Dnmt3a* and *Tet2*, and decreased *Tet1/3* after Coc treatment (p<0,05). Our results further support that cocaine abuse can induce epigenetic changes in different cell types of the testis. Understanding that testicular cells are susceptible to exogenous environmental changes and identifying the type of epigenetic marks that could be altered is critical to detect underlying and transgenerational mechanisms of risk of diseases.

Keywords: cocaine, testis, epigenetic, histone 3, HDAC

(763) **THE IMPACT OF AGE, OBESITY ANDLIFESTYLE UPON ROUTINE SEMEN ANALYSIS PARAMETERS AND SPERM KINEMATICS**

Gustavo Luis Verón (1), Andrea Daniela Tissera (2), Ricardo Bello, Gustavo Estofan (3), Fernando Beltramone (3), Rosa Isabel Molina (2), Mónica Vazquez-Levin (1)
(1) Instituto de Biología y Medicina Experimental (IBYME; CONICET-FIBYME), (2) Laboratorio de Andrología y Reproducción (LAR), (3) Centro Integral de Ginecología, Obstetricia y Reproducción (CIGOR).

Over the past decades, paternal age has increased, and attention has been drawn to aging effects on male reproductive potential. This study aims to report the effect of age upon parameters from routine semen analysis and Computer Assisted Sperm Analysis (CASA) kinematics.In addition, the contribution of obesity, alcohol consumption and cigarette smoking to age-related abnormalities was evaluated.

Semen samples were obtained from men for semen evaluation as part of routine andrology workup (n=12,183) and CASA (n=5,363) at the Laboratorio de Andrología y Reproducción (LAR), Córdoba. Statistical analyses were done with GraphPad-InStat software.

This analysis revealed a negative correlation (P<0.05) between age and routine semen parameters (volume, concentration, motility, vitality, morphology, round cells) and CASA variables (VSL, VCL, VAP, BCF, ALH, MAD). Using 40 yr as a cut-off value confirmed a significant decrease in these parametersin older (≥40 yr) compared to younger (<40 yr; n=2,961 each) men, and an increase in their abnormality rates.

Taking into account the negative impact of clinical and lifestyle conditions upon semen quality, aging was re-evaluated in semen from men unexposed to these conditions. As a result, volume, count, motility, vitality, VCL and ALH were still decreased (P<0.05) in older men. Moreover, obesity (BMI ≥30) proved to negatively add to the detrimental effect of age (lowered volume, concentration, count, motility, morphology, peroxidase-positive cells, VSL, VCL, VAP and ALH; P<0.05). Contrarily, alcohol consumption and cigarette smoking barely worsened aging effects (increased vitality and concentration/count abnormalities, respectively; P<0.05).

Thus, a deleterious effect of age was found upon routine semen parameters and CASA kinematics in a large cohort of samples assessed under same laboratory standards. Furthermore, obesity negatively contributed to the age-related reduced semen quality.

(1292) **CONTRIBUTION OF DIFFERENT SIGNALING PATHWAYS ON THE DEVELOPMENT OF ESTROGEN-INDUCED PITUITARY TUMORS: THEIR ROLE IN SENESCENCE PROCESS**

Bethania Mongi Bragato, Ezequiel Grondona, Liliana Sosa, Lucía Carreño, Juan Nahuel Luques, Juan Pablo Petiti, Silvina Grondona, Alicia Torres, Ana Lucia De Paul
Centro de Microscopía Electrónica - INICSA -CONICET - FCM - UNC

Recently we have demonstrated signs of cellular senescence as a growth control mechanism during the progression of experimental pituitary tumors. Also, it is known that Ras induces negative feedback response on PI3K/Akt and ERK1/2 pathways, while JNK and p38-stress signalling activation mediate key molecular events, which overall trigger the cellular senescence program. Based on these evidences, we aimed to evaluate the contribution these signalling pathways on pituitary cellular senescence during the development of estrogen-induced tumors.

Pituitary tumors were induced in Wistar adult male rats which were implanted with silastic capsules containing estradiol benzoate (30mg) for 10, 20, 40 and 60 days (E10-60). Control group was implanted with empty capsules. Subsequently, phosphorylated (p) and total ERK1/2; AKT; JNK and p38 protein levels were determined by Western blot. Also, pERK1/2, pAKT and senescent associated -b-Galactosidase (SA-b-Gal) double staining was performed in cryosections from normal and tumoral pituitaries. Statistical analysis: ANOVA-Fischer test (p<0.05).

An early pERK activation was detected at E10, followed by the suppression of this pathway, while pAKT expression was inhibited along tumoral progression. Concomitantly, pJNK and p38 progressively increased expression throughout the pituitary tumoral development. By analyzing the joint progression of senescence and proliferation biomarkers, we discriminated differential immunostained areas in which pERK or pAKT positive cells were predominant and adjacent zones were a higher proportion of cells exhibiting SA-b-gal stain.

These results suggest the existence of different regulatory mechanisms that attenuate the mitogenic signals during pituitary tumour development. Concomitantly, molecular events associated with cell senescence are trigged. This study delineates the existence of an intricate signalling network during pituitary tumour development that may be involved in the control of tumoral growth.

(531) **EFFECTS OF *IN VITRO* AND *IN VIVO* BEVACIZUMAB TREATMENT ON PROLIFERATIVE AND ANGIOGENIC PROCESSES IN PROLACTINOMAS.**

Sofía Aylén Valla (1), Gianina Demarchi (1), Agustina Chimento (1), Fernanda Parenti (2), Silvia Berner (3), Carolina Cristina (1)
(1) CITNOBA (UNNOBA-CONICET), Junin. (2) Centro Medico Famyl, Junin. (3) Clinica Santa Isabel, CABA.

Abstract: Prolactinomas are the most frequent type of pituitary adenomas and often acquire resistance to conventional therapies becoming more aggressive and locally invasive. Since angiogenesis plays a key role in tumor development we aimed to study the effect of the VEGF-blocking monoclonal antibody, Bevacizumab, on the prolactinoma cell line MMQ both *in vitro* (25, 100 and 250 μg/ml) and *in vivo* (i.p. twice/week, 3 weeks, 25 mg/kg) in Nude mice injected subcutaneously with MMQ cells. Cell viability was evaluated by MTT assay, mRNA and protein levels were measured by RT-qPCR and WB respectively. We determined a trend of reduction of MMQ cell viability with Bevacizumab treatment (p=0,087, N=4), instead, it had no effect on cell cycle progression or apoptosis rate, both evaluated by flow cytometry (ns, N=4). However, protumoral signaling pathways as ERK (p=0,017, N=3) and AKT (p=0,0002 N=3) were activated compared to control and the expression of the oncogene *C-myc* was increased (p=0,025, N=3). Bevacizumab also increased prolactin protein content (p=0,037, N=3). Regarding angiogenesis, 100 μg/ml Bevacizumab decreased secreted VEGF levels (p=0,054, N=5, ELISA) and showed a trend of reduction of the migratory capacity of HMEC endothelial cells evaluated by wound healing assay. However, increased *Vegf* and *Fgf2* mRNA synthesis was found (p=0,040 and p=0,043, N=3) suggesting that blockade of VEGF action promotes an upregulation of proangiogenic factor transcription. *In vivo*, Bevacizumab decreased tumor growth when injected early in tumor development but increased it when administered later, which correlated with *C-myc* expression. However, mRNA levels of *Prolactin*, PCNA and BETA-CATENIN protein levels were increased independently of initial tumor size. Our results suggest that in the no metastatic pituitary tumors, such as prolactinomas, inhibition of VEGF is beneficial in early stages, but compensatory mechanisms may develop a late refractory response.

Keywords: Prolactinoma, Angiogenesis, Proliferation, Vegf

(1071) **EVIDENCES OF OXIDATIVE STRESS DURING THE DEVELOPMENT OF EXPERIMENTAL PITUITARY TUMOR: CELL DAMAGE RESPONSE AND ITS POSSIBLE CONTRIBUTION TO CELLULAR SENESCENCE**

Ezequiel Grondona, Maria Eugenia Sabatino, Liliana Sosa, Bethania Mongi Bragato, Lucía Carreño, Juan Pablo Petiti, Silvina Gutiérrez , Alicia Torres, Alexandra Latini, Ana L. De Paul

The control of reactive oxygen species (ROS) levels is crucial to guarantee cell survival, since their excessive production is able to promote damages in different cell structures. We have previously demonstrated signs of cellular senescence as mechanism of pro-

liferative arrest and alterations in mitochondrial metabolism and dynamics in experimental pituitary tumors. Since mitochondrial dysfunction has been associated with senescence and this organelle is the main source of ROS, we aimed to analyze the activation of cellular damage response mechanisms to counteract the lesions promoted by oxidative stress.

To promote pituitary tumors, estradiol benzoate was implanted subcutaneously in slow releasing silastic brand capsules (10mg) in adult male Wistar rats for 10, 20, 40 and 60 days. Control group: animals were treated with empty capsules. Subsequently, ROS production was determined by flow cytometry, carbonylated proteins by spectrophotometry; γ-H2AX; 8OHdG, total and phosphorylated Nrf2 and HO-1 was assessed by immunohistochemistry and western blot; OGG1 by PCR; and glutathione levels by colorimetry assays. Statistical analysis: ANOVA-Fischer ($p < 0.05$).

From early stages of tumoral development, a progressive increase in ROS levels was detected accompanied by increases in carbonylated proteins and protein expression of DNA damage markers: γ-H2AX and 8OHdG, exposing signs of oxidative stress. Also, significant increases in OGG1, Nrf2, p-Nrf2 and HO-1 oxidative stress response markers were also observed, in addition to fluctuations in glutathione levels, revealing early antioxidant activation in response to oxidative damage.

Our data demonstrate that oxidative stress response activation triggered during pituitary tumoral development was accompanied by detoxifying mechanisms and DNA damage repair, thus favouring the redox balance recovery and cell survival. These results support the emergence cellular senescence as an intrinsic barrier for the pituitary tumoral growth.

(1093) **EZH2 OVEREXPRESION AND ITS EPIGENETIC MARK H3K27me3 IN PITUITARY TUMOR: ROLE ON CELL CYCLE REGULATION**

Natacha Zlocowski, Liliana del Valle Sosa, Carolina B. Guido, Gabriela D. Moyano, Jorge H. Mukdsi, Juan Pablo Petiti, Alicia I. Torres

Centro de Microscopía Electrónica, Instituto de Investigaciones en Ciencias de la Salud (INICSA-CONICET), Facultad de Ciencias Médicas, Universidad Nacional de Córdoba.

Enhancer of zeste homolog 2 (EZH2) is a core epigenetic regulator, which represses genes involved in tumorigenesis and plays a crucial role in cell cycle regulation. This protein catalyzes the repressive mark H3K27me3 and is associated with proliferation and worse outcome in several tumor entities. Considering the few epigenetics studies in pituitary tumors the aim of this study is to elucidate the effect of EZH2 and H327me3 on cell cycle regulation in order to understand epigenetic´s tumor growth. For this propose we used experimental pituitary tumors induced by estradiol benzoate (30mg capsule) in adult *Fisher* male rats. Experiments were performed with the adenohyphophysis and primary pituitary cell culture, from control and induced-tumoral glands. Protein analysis of H3K27me3 and EZH2 was made through Western Blot and the mRNA levels of cell cycle regulators, *cdkn1a, cdk4, ccdn1 and tp53* was quantified by qRT-PCR. Statistical analysis: t-test ($p<0.05$).

The epigenetic mark H3K27me3 as well as EZH2 were increased in pituitary tumor glands compared to control; being similar in primary culture. In pituitary tumor glands *Cdkn1a* and *tp53* mRNA levels displayed a significant reduction respect to control, but in primary culture this diminution was observed only for *cdkn1a.* The C*dk4* and *ccdn1* mRNA levels did not reveled significant variation in the experimental models used.

The present results suggest the presence of the repressive mark H3K27me3 at *cdkn1* and *tp53* promoters, inferring a regulation of these gens by EZH2.

Bearing in mind that target gens of EZH2 in pituitary tumors have yet to be described, further analysis are needed to better understand the cell cycle regulation, being EZH2 a potentially useful diagnostic marker and pharmacotherapeutic target for this tumor.

Keywords: pituitary tumor, epigenetics, EZH2, H3K27me3

(1611) **FGF2-INDUCED ADENOHIPOFISARY CELL PROLIFERATION IS REGULATED BY INHIBITORY GPCR.**

Liliana Del Valle Sosa (1), Isabella Heirnrich (2), Natacha Zlocowski (1), Florencia Picech (1), Carolina Guido (1), Silvina Gutierrez (1), Juan Pablo Petiti (1), Robrigo Leal (2), Ana De Paul (1), Alicia Torres (1)

(1) Centro de Microscopía Electrónica, INICSA-CONICET, Fac. De Ciencias Médicas, Universidad Nacional de Córdoba. (2) Centro de Ciências Biológicas-Departamento de Bioquímica - Laboratório de Neuroquímica 3 - Transdução de Sinal no SNC, Universidade Federal de Santa Catarina-Florianópolis, Brasil.

The metabolic activity of pituitary gland is regulated by numerous factors being the basic fibroblast growth factor (FGF2), one of the main regulator that increase of pituitary cell proliferation. The growth factors effects may be regulated by activation of inhibitory G protein-coupled receptors (GPCRs) at different signaling levels. The aim of this work was to evaluate whether the FGF2 proliferative activity in adenohypophysis cells is regulated by inhibitory GPCRs activated by the somatostatin analogue, octreotide (OCT). Anterior pituitary cell cultures from female rats were treated with FGF2 (10 ng/mL) or OCT (100mM) alone or co-incubated, in serum free condition. The cell cycle was analyzed using propidium iodide by flow cytometry at 24 and 48h. The mRNA levels of cell cycle regulators (tp53, *cdkn1a, cdk4* and *ccdn1)* were determined by qPCR at 3 or 6h and the total and phosphorylated (p) ERK1/2, JNK, p38 and Akt protein expression by western blot at 15, 30, 60 or 90 min. Statistics: ANOVA-Bonferrony. The S/G2M phases were increased by FGF2 whereas OCT decreased these phases. The FGF2/OCT co-incubation significantly increased the G1-phase arrest after 24 and 48 h, effect that was associated with an increase of *cdkna1* and decrease of *ccdn1* mRNA levels at 3 and 6h, while the *tp53* and *cdk4* did not show any significant variation. In addition, even though pP38 and pAkt protein expression levels did not presented changes, a remarkable decrease of pERK1/2 expression was observed in all times analyzed, and a significant increase of pJNK expression at 60 and 90min was detected after combined treatments These findings show that FGF2/OCT treatment inhibited proliferation induced by FGF2 in pituitary cell culture regulating the pERK1/2 and pJNK protein expression and the c*dkn1a* and *ccdn1* cell cycle regulated genes. This regulatory effect may participate in the homeostasis of pituitary cell populations.

(284) **MECHANISMS OF THE FUNCTIONAL INTERACTION OF RETINOIC ACID AND BMP-4 IN CORTICOTROPHINOMAS**

Leandro Eduardo Nieto (1), Mariana Fuertes (1), Eduardo Arzt (1, 2)

(1) Instituto de Investigación en Biomedicina de Buenos Aires (IBioBA) - CONICET - Partner Institute of the Max Planck Society. (2) Departamento de Fisiología y Biología Molecular y Celular, FCEN, UBA.

Cushing's disease is an endocrine disorder due to a pituitary corticotrophinoma. We demonstrated in dogs the remission after administration of Retinoic Acid (RA). Bone Morphogenetic Protein 4 (BMP-4) also stops the tumoral progression. Our aim is to establish whether there is a common thread between the signaling pathways of RA and BMP-4. Using the AtT-20 mouse tumor corticotroph cell line, we first confirmed the expression pattern of different type of receptors for RA (RXRα, β and γ ; RARβ and γ). By coimmunoprecipitation we observed the interaction of RXRα, RXRγ and RARβ with Smad1 and Smad4 proteins, key components in the BMP-4 signaling, under RA or BMP-4 stimuli for 24h. The transfection with an expression vector for COUP-TFI produced a reduction in the conformation of these complexes. COUP-TFI blocked from 40-80% to 10% the inhibitory action of RA (100 nM) and the potentiation of the inhibition by BMP-4 (100 ng/ml) on the POMC-Luc promoter. We observed that with a POMC-Luc containing both responding elements, RARE and BMPRE, the inhibitory effect of the co-treatment is max-

imum, while with only RARE, RA inhibited and a potentiation of this inhibitory effect was still exerted by the co-treatment with BMP-4. A point mutation at the BMPRE shows that although the promoter does not respond to BMP-4 it still has the co-potentiation action with RA, indicating that BMP-4 does not need the BMPRE site (the main responding element to BMP-4) to potentiate the inhibitory action of RA, that occurs at the RARE site. RA and BMP-4 form signaling complexes that interact at the transcriptional level, resulting in a potential target to treat this disorder.

(1005) **MODULATION OF ANTI-MITOGENIC SIGNALING IN PITUITARY TUMOR CELLS AS NEW THERAPEUTIC STRATEGIES**

Florencia Picech, Liliana Sosa, Gabriela Moyano, Jorge Mukdsi, Alicia Torres, Juan Pablo Petiti
Centro de Microscopia Electrónica, Facultad de Ciencias Medicas, Universidad Nacional de Córdoba, INICSA-CONICET

Clinical treatments for pituitary tumors are focused on stimulating receptors that inhibit proliferation and hormone secretion, such as those for TGFβ1 and somatostatin (SST). However, almost 40% of the patients who receive treatment with SST analogue, Octreotide (OCT), do not respond as expected and the mechanisms underlying this resistance remains still unknown.

Our objectives were to evaluate TGFβ1 and SST receptors expression and to elucidate a possible crosstalk between both pathways in pituitary adenoma cells. We determined the expression of TβRI, TβRII, SSTR2 and SSTR5 by IHC and WB in normal pituitaries (n=7) and in different types of human pituitary adenoma samples: non-functioning (n=9), GH (n=6) and ACTH-secreting tumors (n=2). GH3 rat pituitary tumor cells were treated for 24 h with OCT (10 and 100 nM) and/or TGFβ1 (4 mg/ml). SSTRs and TβRs mRNA was analysed by qPCR, hormone secretion (PRL) by RIA and cell proliferation by ICC for Ki67. Statistics: ANOVA-Fisher, T-Test.

Human pituitary tumor samples exhibited a decreased in SSTRs and TβRs protein expression although variable between different types of adenomas compared to normal pituitaries. In addition, we demonstrated that the co-incubation of OCT with TGFβ1 induced an increase of SSTRs and TβRI mRNA expression, effect that was associated with a decrease of proliferation marker Ki67 and PRL secretion compared to treatments alone ($p < 0,05$).

These findings suggest that pituitary tumor resistance to treatments could be explained, at least in part, by the decreased in anti-mitogenic receptors expression. Furthermore, the synergic effect of OCT and TGFβ1 on cell proliferation and hormone secretion indicate a possible interaction between both anti-mitogenic signals in GH3 cells. Such results highlight the importance of comprehending the connection among different anti-mitogenic signalling pathways and how they can be modulated to obtain a better cell response on the context of tumor resistance to treatments.

(1032) **PRL-3 EXPRESSION IN HUMAN PITUITARY ADENOMAS AND PROLACTINOMA EXPERIMENTAL MODEL: A POSSIBLE ROLE IN THE TUMORAL DEVELOPMENT**

Gabriela Deisi Moyano Crespo, Carolina Guido, Pablo A. Pérez, Silvina Gutiérrez, Florencia Picech, Juan P. Petiti, Alicia I. Torres, Jorge H. Mukdsi
Centro de Microscopía Electrónica

PRL-3 (phosphatase of regenerating liver 3) is a subclass of protein tyrosine phosphatases involved in proliferation, migration, invasion and growth tumor, and have been proposed as potential biomarkers of tumor progression. Our aim was to investigate whether PRL-3 is expressed in pituitary human tumor lesions evaluating its presence and correlating with some clinical-pathological parameters. Besides with the objective to analyze a possible PRL-3 participation in pituitary tumorigenesis, this phosphatase and p21 were evaluated in a lactotroph tumoral experimental model. We analyzed PRL-3 in 46 human pituitary adenomas and Fisher male rats treated with estradiol benzoate (EB) during 10, 20 and 30 days (n: 9) were used. Normal human (n: 2) and rats (n: 3) pituitaries were use as control group (CG). Immunohistochemical technique was applied at photonic and electronic level and a semiquantitave study by western blot was used. Statistic analyzes: x^2 for the variables: size, function and ki 67 in human adenomas. Anova-Fisher and correlate analyze in the experimental model. From the total human adenomas, PRL-3 was expressed in 22 out of 46 with immunolocalization predominantly in cytoplasmic level. Interestingly at ultraestructural level some tumors exhibited phosphatase immunolocalization at plasma membrane. There was a positive relation with tumor size (macroadenomas, x^2 $p<0.0001$). Comparing to normal pituitary gland, PRL-3 showed a significant increase in secreting as well as non-secreting tumors. PRL-3 in experimental prolactinoma showed a significant increase at 20 d EB (hyperplasic/adenomatous state), demonstrating a lineal correlation with p21 (r=0,57). At 30 d EB (adenomatous state) PRL-3 expression decreased without reaching the levels observed in the CG. Our investigation is the first to show PRL-3 expression in human adenomas predominantly in macroadenomas and its involving at the early phases of the pituitary adenomatous development.

Keywords: Pituitary adenoma, Inmunohistochemistry, PRL-3, p21, western blot.

(1021) **TRASTUZUMAB INHIBITS PITUITARY TUMOR CELL GROWTH MODULATING THE TGFB/SMAD2/3 PATHWAY**

Juan Pablo Petiti (1), Liliana Sosa (1), Florencia Picech (1), Pablo Perez (1), Gabriela Moyano Crespo (1), Carolina Guido (1), Eugenia Sabatino (1), Pedro García (2), Verónica Bengió (3), Paula Estario (4), Celina Berhard (5), Silvina Gutierrez (1), Ana De Paul (1), Jorge Mukdsi (1), Alicia Torres (1)

In pituitary adenomas, early recurrences and resistance to conventional pharmacotherapies are common, but the mechanisms involved are still not understood. The high expression of epidermal growth factor receptor 2 (HER2)/ extracellular signal-regulated kinase (ERK1/2) signal observed in human pituitary adenomas, together with the low levels of the antimitogenic transforming growth factor beta receptors (TbRs), encouraged us to evaluate the effect of the specific HER2 inhibition with trastuzumab on experimental pituitary tumor cell growth and its effect on the antiproliferative response to TGFb1. Trastuzumab decrease ($p\leq0.05$) the pituitary tumor growth as well as the expression of ERK1/2 and the cell cycle regulators cyclin D1 and CDK4. The HER2/ERK1/2 pathway is an attractive therapeutic target, but its intricate relations with other signaling modulators still need to be unraveled. Thus, we investigated possible cross-talk with TGFb signaling, which has not yet been studied in pituitary tumors. In tumoral GH3 cells, co-incubation with trastuzumab and TGFb1 significantly decreased ($p\leq0.05$) cell proliferation, and effect accompanied by reduction in ERK1/2 phosphorylation and an increase of SMAD2/3 activation. In addition, through immunoprecipitation assays, an increase in TGFbR1-SMAD2/3 association was observed when cells were co-incubated with the inhibitor of the HER2/ERK1/2 pathway and TGFb1. These findings indicate that blocking HER2 by trastuzumab inhibited pituitary tumor growth and modulated HER2/ERK1/2 signaling and consequently the anti-mitogenic TGFb1/TbRs/SMADs cascade. The imbalance between HER2 and TGFBRs expression observed in human adenomas and the response to trastuzumab on experimental tumor growth, may make the HER2/ERK1/2 pathway an attractive target for future pituitary adenoma therapy.

Our previous results confirmed the presence of stem cell (SC) in adult pituitary gland and provided early evidences of cells expressing cancer stem cells (CSC) markers in experimental pituitary adenomas. The aim of this study was to evaluate possible changes in the expression of CS: GFRa2, Oct-4, Sox2, Nestin, Progenitor (P): Sox9, and CSC: CD133 and CD44 markers, during experimental pituitary tumor development, and later characterization of the SC in culture. The experimental model was performed in female Fischer rats, treated with 30mg of estradiol benzoate during 5 (5D), 10 (10D), 20 (20D) and 30 (30D) days. Control group (C) included rats in diestrous. SC/P and CSC markers were detected by immunofluorescence (IF) and Western Blot (WB). *In vitro* studies were done using C, 5D and 30D pituitary cell suspensions. The spheres were characterized by IF of SC/P and CSC markers and further estrogen stimulation the proliferation of C, 5D and 30D spheres was quantified. SC/P and CSC markers expression was detected in C, 5D and 30D. Oct4, Sox2, GFRa2, Nestin and CD133 showed variations in their distribution within the gland during treatment. We observed positive cells for these markers in the marginal zone (MZ), and low immunostaining in adenohypophysis (AH) of C and 5D. In contrast, their expression was remarkable in AH of 30D, indicating a reorganization of SC from the MZ to AH. The expression levels of GFRa2, Nestin, CD133 and CD44 increased significantly in 5D compared to C and other periods of treatment. Sox2 didn´t show variations on its expression levels and Sox9 (P), decrease in 5D. This allows to propose the participation of CS at early stage of tumor development. The pituispheres in culture were positive for SC/P and CSC markers. A significant increase of proliferation was shown in spheres obtained from 5D and 30D vs. C ($p<0.05$), suggesting that tumoral SC would have a different behavior due to their tumoral imprinting and participate in the neoplastic growth.

(591) **TRASTUZUMAB REGULATES SRC/FAK/PAXILLIN KINASES CONTROLLING ErbB-2 HUMAN BREAST CANCER CELL MOTILITY.**

Joselina Magali Mondaca, Marina Inés Flamini, Angel Matias Sanchez
Instituto de Medicina y Biología Experimental de Cuyo (IMBECU).

Breast cancer is the most common cancer in women worldwide. The majority of deaths attributed to breast cancer are a result from metastasis. Breast carcinoma is classified into molecular subtypes according to the presence and/or absence of estrogen receptors (ER), progesterone receptor (PR) and human epidermal growth factor receptor 2 (HER2). HER2+ breast cancers represent 20-25% of all breast cancer diagnoses. Currently, new anti-HER2 strategies that are used in clinical studies have been developed. One of these strategies is a monoclonal antibody that binds to the extracellular domain of HER2 known as Trastuzumab (Tz). In addition, dimerization of HER2/HER3 receptors regulates diverse cellular functions, including cellular motility. Heregulin (HRG), a HER3 ligand plays a role in the development and progression of breast cancer. However, HRG effects on cell motility have not been fully explored in breast cancer cells. Therefore, the aim of our work is to identify new molecular mechanisms regulated by HRG/Tz on the morphology and motility of BT-474 (HER2+) cells, a Tz-sensitive human breast cancer cell line. We observed in HER2+ cells that, the treatment with HRG (1nM) induced firstly, a significantly phosphorylation/activation and dimerization of HER2/HER3 receptor ($p<0.05$). Secondly, after HER2/HER3 dimerization, HRG caused an increased phosphorylation of c-Src, FAK and Paxillin, ($p<0.05$) and the consequent translocation of p-FAK/p-Paxillin to membrane sites where focal adhesion complexes are assembled. This recruitment of c-Src/FAK/Paxillin is required for cell adhesion, migration and invasion in breast cancer cells, but all of these processes were notably reduced ($p<0.05$) by the use of Tz (10 μg/ml). In conclusion, our findings identify a mechanism whereas HRG and TZ control breast cancer cells motility. This information helps to understand therapeutic approaches for the prevention and regulation of breast cancer in patients with overexpression of HER2.

(1533) **ROLE OF NHE1 AND AQP2 IN BASAL AND ACIDOSIS-ASSOCIATED APOPTOSIS IN A MODEL OF RENAL CORTICAL COLLECTING TUBULE PRINCIPAL CELLS: MPKCCD$_{c14}$.**

Marina Mazzocchi, Micaela Porta, Gisela Di Giusto, Alejandro Pizzoni, Natalia Beltramone, Paula Ford, Claudia Capurro, Valeria Rivarola
Universidad de Buenos Aires. Facultad de Medicina. Departamento de Fisiología. Laboratorio de Biomembranas. Buenos Aires, Argentina. CONICET-Universidad de Buenos Aires. Instituto de Fisiología y Biofísica "Bernardo Houssay" IFIBIO-HOUSSAY. Buenos Aires, Argentina.

The association between growth mechanisms and intracellular pH (pHi) elicits the possibility that a chronic pH alteration modifies cell growth. Control of pHi is regulated in part by the isoform 1 of Na/H exchanger (NHE1), an exchanger that, depending on the cell type, is involved in apoptotic or proliferative processes. We previously showed in renal cells that the expression of aquaporin 2 water channel (AQP2) modifies growth. The aim of this study was to investigate whether exposure of renal cells to acid medium altered apoptosis and, if so, its association with NHE1 and AQP2. To investigate this, we used a kidney principal cell line whose AQP2 expression can be induced by arginine vasopressin (AVP): mpkCCD$_{c14}$. Cell number counting, apoptosis and immunofluorescence studies were performed. Our studies show that after being cultured for 11 days in the presence of AVP mpkCCD$_{c14}$ cells increase their expression of both AQP2 and NHE1. AVP stimulated cells have a higher basal apoptosis than control ones (% apoptosis control 7.75±1.37 vs AVP 13.33±1.85, $p<0.05$ n=7) which decreases by inhibition of NHE1 with its specific inhibitor HOE-694 1μM (% Apoptosis AVP+HOE= 6.33±1.8%, $p<0.05$ vs without HOE n=6). This inhibition of apoptosis is parallel with a 10% increase in AVP stimulated cell number. After exposing 24hs to acid medium (ΔpH = 0.4) only cells that do not express AQP2 significantly increase their apoptosis (% Apoptosis Control+Acid= 21±1.5%, $p<0.01$ n=6) in parallel with a 10% decrease of cell number. The increase of apoptosis in control cell exposed to acid is even greater by inhibiting NHE1 (% Apoptosis Control + Acid+HOE = 27±1.5%, $p<0.05$ vs Acidosis without HOE n=6). This latter apoptosis increase is parallel with 30% decrease in cell number. In summary AQP2 expression protects renal cells of acidosis-induced apoptosis. In turn apoptotic process in these cells is dependent on NHE1.

Vascular calcification (VC) is the leading cause of death in patients with chronic renal failure (CRF) on hemodialysis (HD). The vitamin K-dependent Gla protein matrix is one of the most potent inhibitors of VC and in renal patients it is inactive. This risk of mortality is due in part to the development of the calcification of the middle layer. Objective: To evaluate the effect of vitamin K2 on vascular calcification in patients with CRF in HD of the Center of Dialysis Salta. Materials and Methods: prospective, randomized, double-blind study. Inclusion criteria: men and women ≥ 18 years, HD therapy ≥ 6 months, without oral anticoagulants consumption and signed informed consent. The study subjects (n = 58) will constitute a control group: n = 29 (1000 µl of saline solution) or treated group: n = 29 (1000 µl of Vitamin K2). Vitamin K2 will be administered 3 times a week using the same vascular access, at the end of each dialysis session. Blood samples will be drawn for biochemical determinations: Ca, P, PTHi and KPTT. VC will be evaluated before and after 3 months of treatment by carotid artery intima-mediated echocardiography (IME). We performed Shapiro-Wilks test to analyze normality, F-test to compare variances, Student's t test with Welch modification for normal data with unequal variances and Mann-Whitney test. The statistical package StatGraphics and GraphPad Prism 5 were used. Results: Baseline analysis in patients treated and not treated with Vit K2: Ca 9.2 ± 0.2 vs 9.6 ± 0.5 (p = 0.4); P 5.2 ± 0.2 vs 4.3 ± 0.2 (p = 0.006); PTH 441 ± 104 vs 318 ± 62.8 (p = 0.6). Treated and untreated group: Right IME: 0.63 ± 0.07 vs 1.45 ± 2.1 (p = 0.06). Left IME: 0.73 ± 0.09 vs 0.80 ± 0.1 (p = 0.4). Conclusion: It is expected that vascular calcification does not progress in the treated group when compared with the control group.

Key words: patients on hemodialysis, vitamin K2, vascular calcification.

Renal compromise in patients with systemic lupus erythematosus is an important cause of morbimortality. Experimental evidence suggests the involvement of oxygen reactive species as primary mediators in the pathogenesis of renal damage produced by ischemic, toxic and immunological processes. Our aim was to characterize the redox status in patients with active lupus nephropathy (ALN) and to determine whether any of the oxidative stress (OS) markers studied correlate with the urinary protein/urinary creatinine index (P/Cr), a traditional marker of renal activity. Twenty-two patients with ALN and 25 patients with inactive lupus nephropathy (ILN) were studied. As OS biomarkers we assessed: a) catalase activity (CAT; UI/g Hb) by a kinetic method; b) superoxide dismutase activity (SOD; U/gHb) by a commercial enzymatic technique; and c) lipid peroxidation by the thiobarbituric acid reactive substances method [TBARS; pmol malondialdehyde/g creatinine (pmol MDA/g Cr)]. P/Cr index (g/g) was determined by a colorimetric/kinetic method. The results obtained, expressed as median (range), in patients with ALN and ILN were, respectively, CAT: 33 (6-81) *vs* 35 (6-97); SOD: 971 (258-2280) *vs* 1026 (31-2101); TBARS: 47 (0-172) *vs* 24 (0-157) y P/Cr: 0.83 (0.37-6.6) *vs* 0 (0-0.2). Statistically significant differences between both groups were found for TBARS (p=0.025) and for P/Cr (p=0.001). None of the biomarkers studied significantly correlated with P/Cr. We conclude that, in the sample analyzed, there is a disbalance in the redox status that would be involved in lipid peroxidation of the basal membrane, thus altering its integrity and also affecting tubular function in patients with ALN. Consequently, TBARS could be used as an additional marker of activity in renal disease together with parameters commonly used in clinical laboratory practice.

(760) **EFFECTS OF ESTRADIOL ON CELL PROLIFERATION AND CYCLINS D1 AND B1 EXPRESSION IN PRIMARY CULTURES OF HUMAN RENAL EPITHELIAL CELLS**

Daiana S Sanchez (1, 2), Pablo J Azurmendi (3), Kevin D`Elía (2), Elisabet M Oddo (3), Fernando R Ibarra (1, 2, 3), Claudia Silberstein (1, 2)

(1) IFIBIO-Houssay UBA-CONICET, (2) Dpto. de Fisiología. Facultad de Medicina. Universidad de Buenos Aires, (3) Laboratorio de riñón experimental, Instituto de Investigaciones Médicas A. Lanari, Universidad de Buenos Aires, (4)

The proximal renal tubule epithelium expresses receptors for estradiol, however, little is known about its functions in the kidney. A sexual dimorphism was found in compensatory renal growth, due to the female sex hormones, but the hormonal role in this process is not clarified. The mechanism of cell proliferation is part of the epithelial regeneration process in renal tubules. The objective of the work was to study the effects of estradiol on cell proliferation and the expression of intracellular signals involved in cell cycle, in primary and three-dimensional (3D) cultures of human cortical renal tubular epithelial cells (HRTEC), developed from nephrectomies performed in pediatric patients at the Hospital Nacional Prof. A. Posadas. HRTEC proliferation rate was evaluated by incorporation of bromodeoxyuridine (BrdU), mRNA expression for cyclin D1 (CYD1) and B1 (CYB1) was assessed by RT-qPCR and tubulogenesis was performed in 3D-HRTEC cultures. HRTEC Incubation with 17β-estradiol (17BE 10 nM, 24 h) stimulated the incorporation of BrdU by 40 ± 4,7 % ($p<0,001$, n=8) with respect to control cells without hormonal treatment. HRTEC pre-treatment with ICI182780, a classical estrogen receptors (ER) antagonist, or G-15, a GPER-1 (protein-coupled estrogen receptor-1) antagonist, totally inhibited the effect of 17BE on cell proliferation, without having effect per se. In primary cultures of HRTEC, 17BE significantly ($p <0.01$) stimulated CYD1 (3.6 ± 0.12 fold) and CYB1 (8.3 ± 1.70 fold) mRNA levels with respect to control cells. In 3D-HRTEC cultures, same treatment with 17BE stimulated ($p<0,05$) cell proliferation per tubular structure, which corroborates the stimulation in tubulogenesis, and also significantly ($p<0,01$) stimulated CYD1 and CYB1 genes expression with respect to control 3D-HRTEC. In conclusion, 17BE regulates HRTEC proliferation by stimulating cyclins involved in cell cycle, evidencing a possible role in the regeneration process of human renal tubular epithelium.

Keywords: estrogen, cell proliferation, cyclins, human kidney primary cultures

(1730) **TLR4 REGULATION IN CIRCULATING MONOCYTES FROM PATIENTS WITH TYPICAL HEMOLYTIC UREMIC SYNDROME (HUS+). ROLE OF Rab7b**

Andrea Fernanda Gil Lorenzo

The inflammatory response of host endothelial cells to Shiga toxin and/or lipopolysaccharides (LPS) of *E coli* is included in typical HUS. LPS stimulation of TLR4 activates signal transduction pathways leading to proinflammatory cytokine secretion. The TLR4-LPS complex is rapidly internalized and TLR4-induced inflammatory signaling is stopped by targeting the complex for degradation. Rab7b, a small GTPase expressed in monocytes, regulates the later stages of the endocytic pathway.

We studied the Rab7b participation on the TLR4 endocytic pathway and its effect on monocyte intracellular cytokine production along the acute course of HUS.

The studies were performed in monocytes from HUS patients by flow cytometry and immunofuorescence confocal microscopy.

Surface TLR4 expression determined by flow cytometry in CD14(+) monocytes from 16 HUS patients significantly increased by

days 1 and 4 compared to 10 healthy children monocytes. We show increased proinflammatory intracellular cytokines, tumor necrosis factor alpha (TNF-α), and interleukin 6 (IL-6) in HUS monocytes at days 1 and 4 vs controls. On the contrary, monocytes display decreased surface TLR4 expression and significant reduction of intracellular TNF-αand IL6 levels released in a time-dependent manner after a disease follow up of 6 to 10 days. Furthermore, immunofluorescence confocal microscopy proved colocalization of increased intracellular TLR4/Rab7b determined by Pearson's coefficient in monocytes from HUS patients on day 1. The highest colocalization of both proteins in monocytes was shown by day 4, then decreased TLR4/Rab7b colocalization was shown 10 days after HUS onset.

The colocalization of TLR4 and Rab7b allows us to suggest that Rab7b participates in the control of the TLR4 endocytic pathway in HUS patient monocytes. A consequential fall in cytokine production throughout the early follow up of HUS is demonstrated.

Keywords: TLR4, LPS, Rab7b, monocytes

(1666) **URINE KALLIKREIN ACTIVITY (UKa) IN AUTOSOMAL DOMINANT POLICYSTIC KIDNEY DISEASE (ADPKD)**

María Lucía Rosenberg, Adriana Raquel Fraga, Jorge Eduardo Toledo, Alejandro Fabián Celía, Adriana Rita Scerbo, Pablo Javier Azurmendi, Elisabet Mónica Oddo
Lab. Nefrología Experimental y Bioquímica Molecular, IIM Alfredo Lanari, UBA

The kallikrein kinin system (KKS) is involved in blood pressure regulation and has been proven that UKa is a marker of its renal activity. ADPKD progression is characterized by a progressive renal cyst enlargement that led to chronic renal failure with a wide range of severity. Hypertension and microalbuminuria are early features in ADPKD. These parameters has been found in association with a diminished KKS activity in some renal diseases, but no relevant data on ADPKD is available.

To evaluate KKS in ADPKD, we conducted a transversal study of 17 patients (35 ± 1 years, 7 men) and 5 age-matched healthy controls to measure UKa (U/day), urine osmolality (mOsm/Kg H_2O), osmolal excretion (mOsm/day), diuresis (l/day), blood pressure (mmHg), microalbuminuria (in ug/mg), MDRD-estimated glomerular filtration rate (ml/min/1.73 m2), total kidney volume (TKV in ml) and plasma copeptin as a surrogate marker of vasopressin (ng/ml).

Patients showed diminished UKa (2.83 ± 0.73 vs. 12.27 ± 2.31, $p < 0.0001$) and urine osmolality (221 ± 22 vs. 436 ± 81, $p < 0.01$), increased diuresis (2.39 ± 0.25 vs. 1.54 ± 0.24, $p < 0.03$) and trend to a lower osmolal excretion (472.0 ± 47.6 vs. 583.6 ± 67.2, p = 0.07) than healthy controls. No changes in UKa according to blood pressure levels, sex nor antihypertensive treatment were found. UKa levels correlates positively with TKV and negatively with osmolal excretion (R = 0.73 and R = 0.704, $p < 0.002$; respectively). No association with the other variables were found.

ADPKD patients showed impaired KKS activity that could be attributable to the damage in renal architecture caused by cyst burden. Additionally, UKa could be related to impaired urinary concentration capacity, another early manifestation of the disease. Taken together, these data propose the utility of UKa as a marker of ADPKD progression in an extended and longitudinal study.

Keywords: urine kallikrein activity, ADPKD, total kidney volume, urine osmolality.

(1122) **PROXIMAL TUBULE IN EARLY STAGE OF DIABETIC NEPHROPATHY**

Erika Abril Seyahian (1, 2), Leonardo Cacciagiu (3), Romina Álvarez (1), Adriana Albanese (1), Cristian Costales-Collaguazo (1), Federico Ochoa (1, 2), Alicia E. Damiano (1), Néstor Lago (4), Elsa Zotta (1, 2)
(1) IFIBIO-Houssay-CONICET, (2) Cátedra de Fisiopatología, FFyB, UBA, (3) Laboratorio de Lípidos y Aterosclerosis, Dpto de Bioquímica Clínica-INFIBIOC, FFyB, UBA, (4) CEPEA, FMED, UBA.

Kidneys play a key role in glucose homeostasis. During hyperglycemia a feature of diabetes mellitus, renal glucose handling is altered which in turn leads to an alteration in water transport. Aquaporin 1 (AQP1) is a water channel strongly expressed in proximal tubules. Although 2/3 of filtered water is reabsorbed in the proximal tubule AQP1 expression in diabetic kidneys and its possible role in the alteration of water transport are unknown. Thus we decided to study if AQP1 expression in diabetic kidneys.

Diabetes was induced in Sprague-Dawley rats after intraperitoneal injection of 65 mg/kg Streptozotocin (STZ). Studies were carried out at 15 days and 5 months post injection.

15 days post STZ injection rats presented normal glomerular filtration rate (creatinine clearance 2.3 ml/min ± 0.16 vs 1.9 ml/min ± 0.15 n=6) and no proteinuria. Histological observation revealed no morphological alterations. We considered 15 days post STZ injection representative of early diabetes where there hyperglycemia without renal damage is found. In these rats AQP1 expression significantly increased in the diabetic group (100 vs 198 ± 28, n=3 p<0.05). Functional studies at 5 months after STZ injection revealed that although diabetic rats showed no alteration in glomerular filtration rate (2.09 ± 0.17 ml/min vs 1.95 ± 0.31, n=6) they presented proteinuria (5.04 ± 0.91 vs 18.30 ± 5.12 p<0.05 n=8) and histological alterations. Kidneys were also enlarged. Here, AQP1 expression was significantly decreased (100 vs 49 ± 4.5 p<0,001)

AQP1 expression increases when no renal damage or functional alterations are present. On the other hand in early times of development of diabetic nephropathy, when kidney damage is evidenced by histological alterations and the presence of proteinuria but glomerular filtration rate is still conserved, AQP1 expression is decreased. Further work is needed to establish the relationship between AQP1 and renal glucose handling.

Key words: Kidney. Diabetes. AQP1. Glucose Handling

(1373) CHRONIC KIDNEY DISEASE INDUCED BY LITHIUM IN AN ANIMAL MODEL

Georgina Paula Ossani (1,2), Ana Margarita Uceda (1,2), Juan Manuel Acosta (3), Marisa Gabriela Repetto (3), Néstor Rubén Lago (2), Diego Javier Martino (4), Jorge Eduardo Toblli (1,5)

(3) Facultad de Farmacia y Bioquímica, UBA. (4) Instituto de Neurociencia Cognitiva y Traslacional, CONICET. (5) ININCA-UBA-CONICET.

Lithium (Li) is considered as a first-line drug for the maintenance treatment of bipolar disorder. Interest in the risk of chronic kidney disease and Li-induced renal failure is renewed due to findings suggesting that both complications would be more frequent than previously estimated. The aim of this work was to evaluate renal damage due to chronic exposure to Li. Wistar male rats (n=39) were fed standard diet (Control -C-) or a containing 60 mmol Li/kg diet (Experimental -E-) ad libitum and sacrificed after 1 or 3 months of treatment (1 or 3). Clearance of creatinine (CrCl), lithemia, urin protein excretion (UPE) and fractional excretion of sodium (FENa) were measured. Kidney samples were processed for: 1-histology and morphometric analysis (PAS and H&E); 2-oxidative stress (TBARs and carbonyls) evaluation; 3-immunohistochemistry (Aquaporin-2; AQP2). FENa and UPE were within normal values in all groups. Lithemia (mmol/L) reached therapeutic values in both E groups (E1=0.57±0.18 and E3=0.68±0.12). CrCl was markedly reduced after 3 months of Li administration (C3=2.75±0.47 vs E3=1.55±0.75; t=4.18, p=0.001). Kidney from both E groups showed dilatation of the cortical collecting tubules (CCT), identified with AQP2 positive staining. Some CCT had hypertrophy with enlarged, binucleated cells, protruding into lumen and other CCT had atrophy with flattened cells. Glomerular area -μm^2- was smaller in E rats (C1=11333±2067 vs E1=9757±2178; t=1.58, p=0.135 and C3=13103±1494 vs E3=11053±929; t=3.76, p=0.001). A significant increase in TBARs -nmol/mg-(C1=0.36±0.10 vs E1=0.51±0.11; t=-3.02, p=0.008 and C3=0.36±0.08 vs E3=0.58±0.15; t=-4.02, p=0.001) and carbonyls -nmol/mg-(C1=0.23±0.07 vs E1=0.33±0.06; t=-3.27, p=0.004 and C3=0.24±0.07 vs E3=0.36±0.10; t=-3.24, p=0.005) was observed in both E groups. Exposure to Li from 1 to 3 months induced renal

damage resulting in histological and functional alterations, changes in glomerular area and increase of oxidative stress and damage.

Keywords: Lithium, Chronic Kidney Disease, Histopathology, Renal Function, Oxidative Stress

(1312) **ENDOTHELIN AND RENAL POSTNATAL DEVELOPMENT: MOLECULAR MECHANISMS INVOLVED**

María Del Carmen Ortiz, María Florencia Albertoni Borghese, Milena Palamidessi, Lucas Oronel, Rocío Marinoni, Carolina Yarza, Celeste Sanz, Mónica Patricia Majowicz
Cátedra de Biología Celular y Molecular; Facultad de Farmacia y Bioquímica, UBA.

Disturbances in proliferative and apoptotic processes during development manifest as development abnormalities. Diverse studies have implicated apoptosis as a determinant of nephron number, being mainly implicated the intrinsic or mitochondrial pathway of apoptosis. The aim of this work was to evaluate in the renal cortex of seven days old Sprague-Dawley rats (both male and female) treated with bosentan (dual endothelin receptor antagonist) from the first day of life: 1) cellular proliferation by immunohistochemistry using a primary antibody anti PCNA (Proliferating cell nuclear antigen); 2) cellular apoptosis by TUNEL (Terminal deoxynucleotidyl transferase dUTP nick end labeling) assay and 3) TBARS (thiobarbituric acid reactive substances) to estimate oxidative stress. Four experimental groups were defined as follows: control male (CM); control female (CF); bosentan male (BM) and bosentan female (BF). Two factor ANOVA was used for the statistical analysis.

The number of PCNA positive nuclei present in the immature structures that give rise to glomeruli did not change significantly in bosentan-treated vs non-treated animals in the cortical [CM= 426±11; BM= 406±10; CF= 589±123; BF= 520±165] nor in the juxtamedullary area (JA) [CM= 650±21; BM= 615±69; CF= 856±17; BF= 639±116]. However, the number of TUNEL positive nuclei was significantly higher in bosentan-treated animals, mainly in the JA [CM= 14±4; BM= 79±27; CF= 8±1; BF= 42±17 ($p<0.01$)], in accordance with our previous results showing a decreased glomerular number in that zone (PLOS ONE 11(2): e0148866. doi:10.1371/journal; 2016). There was a tendency to increase TBARS in BM vs CM [0.885±0.171 vs 0.674±0.073 (nmol MDA/mg. prot)].

Endothelin inhibition during the postnatal period produces an imbalance between renal proliferative and apoptotic processes, being exacerbated apoptosis with a decreased proliferation/apoptosis ratio and this may be a consequence of an increased oxidative stress.

Key words: Endothelin, endothelin receptor antagonist, bosentan, renal postnatal development.

(1094) **A MASS SPECTROMETRY-BASED UNTARGETED METABOLOMICS APPROACH FOR STUDYING CLEAR CELL RENAL CELL CARCINOMA USING AN *IN VITRO* MODEL**

Malena Manzi (1), María Elena Knott (1), Nicolás Zabalegui (1), Mario Omar Salazar (2), Lydia Inés Puricelli (3), María Eugenia Monge (1)

Roffo, Ciudad de Buenos Aires, Argentina.

Renal Cell Carcinoma (RCC) is among the 10 most common cancers in both men and women worldwide, with clear cell RCC (ccRCC) being the most common (75%) histological subtype. At molecular level, 90% of all ccRCC patients show mutations in Von Hippel Lindau (VHL) gen which is involved in Hypoxia Inducible Factor 1α expression. Current research has shown that several metabolic alterations are associated with RCC, during tumor progression and metastasis. Mammalian cell metabolomics has emerged as a promising tool for studying cellular biochemistry and investigate altered metabolic networks that contribute to cell proliferation, growth and survival in RCC.

In this study, we have optimized a protocol for harvesting, extraction, lyophilization and reconstitution of metabolites present in conditioned media derived from human ccRCC cell lines 786-O ($VHL^{-/-}$) and Caki-1 ($VHL^{+/+}$), and the non-tumor human cell line HEK-293 (n=22); and we have profiled the exometabolome using a discovery-based metabolomics approach by means of ultraperformance liquid chromatography coupled to quadrupole-time-of-flight mass spectrometry (UPLC-QTOF-MS). Metabolic features (Rt, *m/z* pairs) were analyzed using a cross-validated orthogonal projection to latent structures-discriminant analysis model, using a genetic algorithm variable selection method. A panel of 12 discriminant features with tentative chemical identification allowed differentiating the three cell lines with 100% specificity, sensitivity and accuracy. In addition, 5 of these compounds were present in 10 human serum samples from ccRCC patients and healthy controls. Discriminant metabolic features suggest alterations of the glutathione and phenylalanine metabolism, tryptophan degradation and the pentose phosphate pathway. Current work involves validation of the tentative identification of the compounds with chemical standards.

Keywords: untargeted metabolomics, conditioned media, statistical multivariate analysis, mass spectrometry

(1747) **GENDER DIFFERENCES IN RENAL RESPONSE TO HIGH SODIUM INTAKE IN ADULT NORMOTENSIVE WISTAR RATS**

Luis Alberto Di Ciano (1), Pablo J. Azurmendi (1), Sandra G. Vlachovsky (1), Elisabet M. Oddo (1), Elvira E. Arrizurieta (1,2), Claudia M. Silberstein (2,3), Fernando R. Ibarra (1,2,3)
(1) Laboratorio de Riñón Experimental y Bioquímica Molecular, Instituto de Investigaciones Médicas A. Lanari, UBA. (2) CONICET. (3) Departamento de Ciencias Fisiológicas, Instituto de Fisiología y Biofísica Bernardo Houssay (Infibio Houssay).

There is a gender difference in the regulation of renal function and blood pressure in humans and also in several experimental animal models. We studied the renal response to high sodium intake in male and female Wistar rats.

The experiments were performed in intact male (IM), female (IF) and Gonadectomized (GX) Wistar rats at 150 days of life. Half of them were Orchidectomized (ORX) or ovariectomized (OVX) at 60 days of life and supplemented or not with testosterone propionate (ORXTo), 17β estradiol 3-benzoate (OVXE2) or medroxyprogesterone acetate (OVXP4) at 138 days of life , using cholesterol (CHO) as vehicle. During the last 5 days of the study, half of rats received normal sodium (NS, NaCl 0.24%) or high sodium diet (HS, NaCl 1% in drinking water). Glomerular filtration rate (GFR), renal plasma flow (RPF), sodium excretion (mmol/d/g kw) and mean arterial pressure (MAP, mmHg) were measured. To analyze the response of renal function upon HS, mRNA (Atpa1a) expression by RT-PCR and dephosphorylated Na+,K+-ATPase (dNKA), dopamine-D1-receptor (D1R), cytochromeP450A (CYP4A), Na+,K+,2Cl- (NKCC2) and Na+/Cl- (NCC) cotransporters were determined in renal tissue by western blot.

Under HS, both IM and IF do not change MAP and IF excrete more sodium and showed lower medulla dNKA, Atpa1a, cortical NCC and NKCC2 than IM. OVX excrete less sodium and ORX excrete more sodium than their intact ones and both increase MAP (all $p<0.05$).

The increase of MAP in OVX is a consequence of a defective D1R-CYP4A pathway, which results in more active dNKA and to a higher expression of NKCC2 and NCC, whereas it could be due to changes in GFR and RPF in ORX. E2, but not P4 or To prevented the increase in MAP.

There is a sexual dimorphism in renal function and blood pressure. Gonadectomized rats behave as a model of salt sensitivity. Findings provide a better understanding of gender differences in renal function.

Keywords: renal Na+,K+-ATPase; gonadectomy; dopamine; sex hormones; salt-sensitive hypertension.

Soil Transmitted Helminth (STH) infections directly impact nutritional status, educational development, individual productivity, and physical and mental development in human populations. Currently, these infections are controlled through mass drug administration (MDA) programs using albendazole (ABZ) or mebendazole. However, not all programs have demonstrated expected impact on prevalence or intensity of infections. These failures may be related to poor programmatic coverage, suboptimal adherence or the exposure of parasites to sub-therapeutic drug concentrations due to poor drug dissolution, insufficient gastrointestinal absorption and/or systemic availability of the active ingredient.

The aims of the present work were to characterize the serum disposition kinetics and pattern of urinary excretion of ABZ and its main metabolites, ABZ sulphoxide (ABZSO) and ABZ sulphone ($ABZSO_2$) in human volunteers, and to determine the optimal time point where ABZ and/or its metabolites can be measured in urine as an indirect assessment of an individual's adherence to treatment. Venous blood and urine samples were collected from eight (8) volunteers between 2 and 72 h for HPLC analysis of ABZ/metabolites, following administration of a single postprandial oral dose of ABZ (400 mg). The ABZSO metabolite was the main analyte recovered either in serum and urine samples from ABZ-treated human. ABZSO serum concentrations reached its peak concentration (Cmax= 1.20 **±** 0.44 µg/mL) at 4.75 h post-treatment. In urine, ABZSO Cmax value was 3.24 ± 1.51 **µg/mL,** reached at 6.50 h post ABZ administration. The urinary AUC value resulted higher (2.3 fold) compared to that measured in serum. The overall, PK-based information reported here demonstrates that the measurement of ABZSO concentrations both, in serum and urine, could be useful to confirm compliance to ABZ treatment and an objective measurement of program coverage.

(1766) **AZILSARTAN AND ITS Zn(II) COMPLEX. SYNTHESIS, ANTICANCER MECHANISMS OF ACTION AND INTERACTION WITH BOVINE SERUM ALBUMIN**

Azilsartan is the eighth approved member of angiotensin II receptor blockers for hypertension treatment. Considering that some drugs have additional beneficial effects on health when administered, we studied its effects and mechanisms of action on a human lung cancer cell line A549. We have also modified the structure of the drug by complexation with Zn(II) cation and determined the anticancer effect. The crystal structure of the new binuclear Zn(II) complex, for short $[Zn_2(azil)_2(H_2O)_4].2H_2O$ (ZnAzil), was determined by X-ray diffraction methods. A549 and MRC-5 cell lines were used for the anticancer determinations. The results of the MTT assay showed that the complex behaved as good antiproliferative agent (IC_{50} = 155 μM ± 12, p<0.05) without exerting cytotoxic effects on MRC-5 cells. The complex generated reactive oxygen species (ROS) in the cells. This effect was accompanied by glutathione (GSH) depletion and a decrease in the GSH / GSSG ratio. The characteristic apoptotic morphology could be observed by the double staining acridine orange/ethidium bromide and the percentage of apoptotic A549 cells treated with the Zn complex resulted higher (46%, p<0.05) than those of control cells and cells treated with the biometal (10%, p<0.05) and azilsartan (3%, p<0.05). The evaluation was complemented by Western Blot of pro-apoptotic proteins BAX, antiapoptotic BCL-XL and Caspase-9 determinations. The complex showed increase in the Caspase-9 expression and the calculated BAX/BCL-XL ratio (p < 0.05). Additionally, we have evaluated the interactions of the compounds with bovine serum albumin (BSA). Measurements indicated that the complex and the ligand exhibited a strong binding to BSA. All these results suggested that the Zn complex induces apoptosis through ROS-dependent mitochondria pathway in lung carcinoma cells and be effectively transported in plasma. This compound behaved as a potential candidate for alternative cancer treatment.

Keywords: azilsartan, Zn complex, anticancer, BSA binding

(1120) **CHRONIC INTAKE OF *ERUCA VESICARIA* LEAVES EXTRACTS ALTERATES METABOLIC PROFILE AND INTESTINAL EFFLUX TRANSPORTERS ACTIVITY IN RATS**

Martín Ignacio Roma (1), Victoria Schiariti Lampropulos (2), Fernanda Defino (1), Marcela López Nigro (2), Marta Carballo (2), Roxana Noemi Peroni (1)

(1) ININFA, (2) INFIBIOC

Increasing evidence implicates dietary factors in the progression of diseases, including cancer, diabetes and obesity. Diet also regulates ABC transporter expression and function impacting on drug elimination.

The goal of the present study was to evaluate the activity of intestinal ABC transporters and metabolic profile after chronic intake of *Eruca vesicaria* leaves (arugula commercial variety).

Adult male and female Sprague Dawley rats (20 weeks, n = 21) received an oral dose of *E. vesicaria* leaves juice representing human average intake (2g/kg), a methanol extract or saline solution three times a week during 4 weeks. Serosal to mucosal transport of substrates by MRP2, P-gp and BCRP was measured in everted sacs of proximal jejunum, distal jejunum and ileum, respectively. Glycaemia, triglycerides and cholesterol were determined.

Juice intake decreased MRP2-mediated efflux of doxorubicin in males (p<0,05) and females (p<0,001) and increased BCRP-dependent passage of nitrofurantoin selectively in male rats (p<0,01). In turn, methanol extract intake decreased MRP2 activity only in males (p<0,05); while in BCRP a dual behavior was found, increasing its activity in males (p <0.05) and decreasing it markedly in females (p <0.001). In turn, no changes in P-gp activity were observed under any of the treatments. Moreover, methanol extract increased glycaemia in males (p<0,05) and females (p<0,01) as well as triglycerides (p<0,05) in males. No metabolic changes were found after chronic intake of juice.

Present findings indicate that methanol or aqueous extract may enhance and/or suppress xenobiotics or drugs bioavailability and caution should be paid to the possible influence on metabolism. Despite the extracts natural origin, an overall evaluation of the balance between beneficial vs. adverse effects for each secondary active metabolite should be performed.

Keywords: ABC efflux pumps, pharmacokinetics.

(152) **DERIVATIONS FROM PHARMACOKINETIC ANALYSIS OF A CLARITHROMYCIN EXTENDED RELEASE FORMULATION**

Hector Alejandro Serra (1), Eduardo Gallardo (2), Francisco Bagnato (1), Mikhail Morozov (1), Leonardo Rizzo (3)

(1) Cátedra de Farmacología, Ciencias Médicas, UCA. (2) EGCP Global Clinical Practice. (3) Dirección Médica, Química Montpellier SA.

A study on bioavailability of a new clarithromycin extended release formulation (provided by Química Montpellier SA) let some interesting pharmacokinetic data. A more detailed analysis of elimination kinetics showed 2 groups with important differences. The aim of this paper is to describe these findings. 24 both gender healthy volunteers (33% women, age 20-58 years) participated in this typical cross-design bioequivalence study. Each volunteer randomly received clarithromycin 1 g from different oral formulations in 2 separate rounds by 7 days and 11 blood - 5 urine samples were taken per round to determine the antibiotic profile. It were defined Cmax, tmax, AUCt, AUCinf, elimination half-life, mass of antibiotic recovered in urine during that period, and calculated total Vd(F), total Cl(F), renal and non-renal Cl. As both formulations were equivalent, all elimination data were analyzed by t-test. Population covariates were analyzed by chi-square test. Assuming elimination half-life 10 h as cutoff value, 65% of the volunteers (fast eliminators) had lower values; X = 6.94 ± 1.71 h, and the remaining 35% (slow eliminators) had significantly higher values; X = 16.57 ± 5.58 h (p <0.001). Total Cl(F), renal and non-renal Cl per group in L/h, expressed as X ± SD, were respectively: 27.34 ± 8.10 vs. 19.87 ± 4.82 (p <0.001); 7.51 ± 3.25 vs. 7.85 ± 3.25 (ns), and 19.83 ± 8.50 vs. 12.02 ± 5.05 (p <0.001). The aforementioned data were not correlated with age, gender, or body mass index. The results indicate that such differences in the elimination of clarithromycin could be due to non-renal Cl, and other covariates do not influence this behavior. These differences are not clearly reported previously. Subsequent studies should be performed to confirm or rule out these findings.

Keywords: clarithromycin, pharmacokinetics, non-renal clearance

(1228) **DETERMINATION OF THE PHARMACOKINETICS OF CEPHALEXIN 20% ADMINISTERED SUBCUTANEOUSLY IN LACTATING GOATS**

María Mercedes Alonso, Jonathan Rodriguez Paes, Ana Paula Prados, Fernando Suarez Belzoni, Verónica Elizabeth Kreil

Universidad de Buenos Aires, Facultad de Ciencias Veterinarias, Farmacología

The rational use of antimicrobial agents in goats productive systems may contribute to decrease economical lost. Cephalexin is a first generation cephalosporin, active against gram positive microorganism and gram negative bacillus. The sustained release cephalexin formulation (20 %) is used in veterinary medicine, prolonging the duration of the antibacterial activity (long-acting formulations). The aim of this study was to describe the pharmacokinetics of cephalexin 20% after subcutaneous administration in lactating goats. Six healthy lactating goats (weight average 35.52±4.50 kg) received a single dose of 20 mg/kg of a sustained release cephalexin (Cephalexin 20%, Laboratorio Ruminal, Buenos Aires, Argentina) by the subcutaneous route (s.c.) under a skin fold on the lateral of the thorax. Heparinized blood samples (2.5 ml) were collected via jugular venepuncture in preestablished times. Plasma samples were frozen at - 20° C until analysis. Plasma concentrations were determined by the microbiological method, using *Kocuria rizophila* ATCC 9341 as pattern microorganism. Standard curve was validated in plasma for linearity (r2: 0.988), accuracy (13.72%) and precision (3.72%) between 50 and 0.39 *µ*g/ml. The results were analyzed using Graph Pad Prism, Excel and Topfit. The quantification and detection limits of the method were 0.78 *µ*g/ml and 0.39 *µ*g/ml, respectively. Pharmacokinetic parameters were: Cmax: 20.40± 3.24 *µ*g/ml; Tmax: 1.20 ± 0.54 h; t½: 1.29± 0.48 h and TMRinf: 2.44± 0.82 h. The dosage and route of administration are the recommended by the manufacturer for cattle. Cephalexin is a time dependent antibiotic and the pharmacokinetic profile in goats for the sustained released formulation showed that the administration every 12 hours by the s.c. route would be appropiated for the treatment of micro-organisms with MIC £ 1 microgram/ml.

Key words: pharmacokinetics, Cephalexin, goats, lactation

(715) **EFFECT OF FLUNIXIN ON INTRAMUSCULAR ENROFLOXACIN KINETICS IN CALVES**

Guillermo Fermín Prieto (1), Carlos Alberto Errecalde (1), Natalia Urzúa Pizarro (1), María Paula Tonini (1), Carlos Luders (2)

(1) Farmacología, FAV, UNRC. (2) Farmacología, Univ. Temuco, Chile.

Enrofloxacin (EFX) belongs to fluoroquinolone family, targeting gram-negative and some gram-positive bacteria as well as *Mycoplasma* spp. Flunixin (FL) is a nonsteroidal anti-inflammatory drug (NSAID) inhibiting cycloxygenase enzymes in the arachidonic acid cascade, blocking the formation of inflammatory mediators. NSAIDs are frequently coadministered to enhance the rate of recovery in combination with antimicrobial drugs in calves suffering from endotoximia, pneumonia and other viral and bacterial respiratory diseases. However, it has been reported that the distribution and elimination of antimicrobials are altered when they are coadministered with NSAIDs.This work was performed to characterize EFX disposition and establish the influence of the coadministration of FL on kinetic parameters. Lactating calves (N= 6) received 5 mg of intramuscular EFX, a week later 5 mg / kg of EFX and 2.2 mg of flunixin meglumine intramuscularly. At different times for 24 hours blood samples were obtained, centrifuged and stored at -20 °C. The preparative test consisted of extraction of the analyte with 200 µL of plasma, 200 µL of water, 750 µL of methanol: water: acid: phosphoric acid (500: 500: 10: 1 v / v / v / v) and 50 µL of 25% trichloroacetic acid. The whole was stirred 30" in vortex and centrifuged 30 minutes at 13500 rpm at 4 °C. Separation and quantification were performed by reverse phase isocratic elution with C-18 column and reading in fluorescence detector at λex 295 nm y λem 490, mobile phase composed of water, acetonitrile and triethylamine (79: 20: 1 v / v / v) at pH 3. Plasma concentration data were analyzed by PK Solution 2.0 software to calculate robust kinetic parameters. Results indicates rapid absorption and distribution of EFX and moderate permanence in the organism. Statistical non-parametric Mann-Whitney test was used. It can be verified that the coadminstration of FL did not significantly modify (P <0.05), the kinetic parameters of marbofloxacin.

Key words: flunixin, marbofloxacin, pharmacokinetics, calves

(251) **HUMAN PLASMA PROTEIN BINDING OF NOVEL ZIDOVUDINE PRODRUGS: TARGETING SITE 2 OF HUMAN SERUM ALBUMIN**

Mario Alfredo Quevedo, Sergio Román Ribone, Esteban Martín Schenfeld

Unidad de Investigación y Desarrollo en Tecnología Farmacéutica (UNITEFA-CONICET)

The binding of anti HIV drugs to plasma proteins is key to their antiviral efficacy. Human serum albumin (HSA) constitutes the main plasma protein that binds and transport drugs, with several binding sites been reported. In this work, we explore the binding of the zidovudine (AZT) and AZT prodrugs obtained by combination with organic diacids (succinic (Suc), glutaric (Glu) and adipic (Adi) acid) and a methylated phenylalanine moiety. The binding of AZT-Suc-Ph (**1**), AZT-Glu-Ph (**2**) and AZT-Adi-Ph (**3**) to plasma proteins was studied experimental and molecular modeling techniques.

The binding of AZT and **1-3** was measured by incubating solutions of the prodrugs (9*µ*M, 37°C) with human plasma (HP), isolating the free fraction by ultrafiltration. The binding site to HSA was determined using salicylic acid (SA) and diazepam (DZP) as site 1 and 2 markers, respectively. The prodrugs exhibited a significantly increased binding to HP (**1**: 52.1±5.3%, **2**: 59.7±4.3% and **3**: 72.5± 4.3%) compared to AZT (13.8±1.4%), with their bound fraction being slightly displaced by DZP, indicating a high affinity for site 2 in HSA. Molecular docking and free energy decomposition analyses were applied to study the interaction of DZP and **1**-**3**. While DZP maintained the interaction pattern observed in the crystallographic structure, with a binding driven mainly by hydrophobic interactions, prodrugs **1**-**3** positioned the aromatic ring within a highly buried hydrophobic subpocket of site 2, establishing a higher number of interactions. The calculated interaction energies were: -12.26 kcal/mol (DZP), -13.22 kcal/mol (**1**), -14.13 kcal/mol (**2**) and -19.26 kcal/mol (**3**), evidencing that the prodrugs exhibited a more stable interaction with HSA than DZP. A correlation between the bound fractions and the interactions energies was found. In conclusion, the novel prodrugs exhibited a higher affinity for HSA than AZT and a change in

their binding site, which may in turn result in different pharmakinetic properties.

Keywords: Zidovudine, prodrugs, HSA, binding, molecular modeling.

(749) **INTRAMUSCULAR PHARMACOKINETICS OF MARBOFLOXACIN 10% IN WEANING CALVES**

Carlos Alberto Errecalde (1), Guillermo Fermín Prieto (1), Carlos Luders (2), Natalia Urzúa Pizarro (1), María Paula Tonini (1), María Emilia Errecalde (1)
(1) Farmacología, FAV, UNRC, (2) Farmacología, Univ Católica Temuco, Chile.

Marbofloxacin (MBX) is a fluoroquinolone applied only in domestic animals. It exhibits favorable kinetic properties and excellent activity against gram-negative microorganisms and mycoplasmas. This study was to determine kinetic parameters after the single application of MBX (Marbocyl 10%, Vetoquinol, Spain) and to evaluate its therapeutic usefulness. Twelve healthy calves of 29 ± 5 days of age, 46.4 ± 10.5 kg of body weight, clinically healthy, received a single 6 mg / kg dose of marbofloxacin intramuscularly. At different times up to 24 hours post-application blood samples were taken in heparinized tubes, centrifuged and stored until analyzed by HPLC. The preparative test consisted in the extraction of the analyte using 200 μL of sample, 200 μL of water, 800 μL of methanol and enrofloxacin as an internal standard. The assembly was stirred for 30" in vortex and then centrifuged 25 minutes at 13.500 rpm at 4 ° C. Separation and quantification was performed by isocratic elution in reverse phase using C-18 column and fluorescence detector reading set at 295 nm excitation and 490 nm emission, mobile phase composed of water, acetonitrile and triethylamine (79: 19: 1 v / v / v) at pH 3. Plasma concentration data were analyzed by PK Solution 2.0 software to calculate robust kinetic parameters. Intramuscular administration determines prompt absorption, Cmax of 5.0 ± 1.5 µg / ml obtained at 1.7 ± 1.01 hours. MBX exhibits moderate tissue distribution, extensive permanence in the organism according to the parameters of Vd_{area} and TMR. The results obtained agree with the kinetic profile demonstrated by MBX in domestic animals and suggests its application in infectious diseases caused by germs with MIC ≤ 0.13 µg / ml, according to predictors of efficacy used for fluoroquinolones, ABC / CMI and Cmax / CMI.

(892) **IDENTIFICATION OF BENZNIDAZOLE METABOLITES IN URINE FROM PATIENTS WITH CHAGAS DISEASE**

Daniela Marisa Rocco, Carlos Alberto Pérez Montilla, Samanta Moroni, Facundo García Bournissen
Hospital de Niños Dr. Ricardo Gutiérrez

Chagas disease is a major public health problem in Latin America. Benznidazole is an effective treatment but has several side effects.

Information about benznidazole metabolism it is scarce although there is limited evidence that conjugation with glucuronic acid by glucuronosyltransferase (i.e. phase II reaction) is involved, but it is not clear if benznidazole is directly conjugated or an intermediate phase I metabolic step takes place.

The objective of this study was to characterize benznidazole metabolites in human 24 hours urine samples from patients with Chagas disease receiving benznidazole treatment.

Samples from 3 adult female patients in the chronic stage of Chagas disease, treated with benznidazole 7 mg/kg/day for 30 days were obtained near the end of treatment. Urine from 3 healthy female adult were used as controls.

Samples were analyzed using ultra-high performance liquid chromatography coupled to a triple quadrupole mass spectrometer (UHPLC-ESI-QqQ) in Q_1-Full Mass Scan, Neutral Loss (NL) and Multiple Reaction Monitoring (MRM) mode.

Initially samples were studied using Q_1 -Full Mass Scan mode and NL mode to identify mass loss of 176 units corresponding to glucuronic acid loss after fragmentation. Once relevant peaks were identified by comparison to control urine MRM mode was developed using their transitions to confirm results.

Benznidazole glucuronides were not observed, but two different benznidazole metabolites possibly from phase I reactions were observed: aminobenznidazole (m/z 231) and hydroxyaminobenznidazole (m/z 247). Both metabolites were found in free form and conjugated with glucuronic acid (m/z 407 and m/z 423).

Identification of these metabolites opens the door for future studies to clarify the metabolism of benznidazole in patients and its potential consequences including drug interactions.

Keywords: benznidazole, metabolites, mass spectrometry.

(587) **R-SHINY APPLICATIONS FOR PK-PD: CLARITHROMYCIN PK AS AN EXAMPLE**

Mikhail Morozov, Ezequiel Nuske, Héctor Alejandro Serra
Cátedra de Farmacología, Ciencias Médicas, UCA

Population PK-PD models play an important rol in drug research and development. The nonlinear mixed effects model is the most used. R is an open-source programming and data analysis language very useful to predict data behavior, a task that invariably requires simulation. R has several advantages over commercial software such as SAS. However, R shows pitfalls when presenting results, such as the static nature of the output. Thus, interactive elements, as Shiny, have recently been added to R libraries in order to improve the user interface.

This work shows a population PK simulation for clarithromycin in an extended release formulation using R and Shiny. For the kelim and total Cl (F) elimination data from 24 volunteers -0.084 ± 0.041 h^{-1} and 25.0 ± 8.4 L/h provided by a bioavailability study; R simulated using 1000 volunteers a population value of -0.073 and 22.66 respectively.

Using the appropriate model, R-Shiny can simulate and display the interesting changes in covariates or in model parameters quickly, through friendly and intuitive widgets. To construct the Shiny interface, medium-level programming skills are required, but simulating a given situation with Shiny (if it had properly programmed ad hoc) is accessible to all biomedical or clinical researcher.

Keywords: Population pharmacokinetics, R-Shiny program language, nonlinear mixed effects model

(1078) **SPERMATOZOA CAPTURE AND EFFICIENTLY TRANSMIT ZIKA VIRUS TO EPITHELIAL AND DENDRITIC CELLS.**

Augusto Varese, Ana Paletta, Melina Gonzalez Prinz, Federico Remes Lenicov, Fernando Erra Diaz, Alvaro Lopez Malizia, Juan Sabatté, Jorge Geffner, Ana Ceballos
INBIRS

Zika virus (ZIKV) infection was associated to new born microcephaly and to Guillain-Barre syndrome in adults. Surprisingly, it has been reported sexual transmission of ZIKV, changing our view of arbovirus-host interaction. Infectious ZIKV persist in semen after symptoms onset and at higher viral loads than those found in plasma or urine. Knowing that semen is not merely a carrier for sexually transmitted diseases, we developed experiments to evaluate the role of spermatozoa (sp) in ZIKV transmission.

Sp were obtained from healthy donors by swim up purification. Dendritic cells (DC) were obtained from monocytes (GM-CSF/IL-4 5 days); phenotype was analyzed by flow cytometry and cytokines production by ELISA. ZIKV capture and infection was evaluated by qPCR.

Sp (10, 5, 1, 0.5 $x10^6$) were incubated with ZIKV ($5x10^5$ ufp) 90 min, then cells were washed twice to remove free virus. We observed that sp captured ZIKV (n=3 $p<0.05$) and trypsin pretreated sp (15 min 37°C) showed no ZIKV attached (n=3 $p<0.05$), suggesting a protein mediated interaction. To evaluate if sp was able to transmit ZIKV, sp charged with ZIKV were cultured with epithelial cells monolayers or DC ($2x10^5$/200ul) for 72hs. We observed that sp+ZIKV were able to transmit the virus to cells (n=3 $p<0.001$). Even more, when the same quantity of ZIKV was offer to cells without sp, we found the levels of infection were lower (n=3 $p<0.005$), so sp facilitate the infection.

Lastly we analyzed the phenotype and functionality exerted by ZIKV to DC. DC ($2x10^5$/200ul) were infected with ZIKV ($5x10^5$ or $5x10^4$ ufp), 72hs later we found: an increase of CD86, CD83, CD80 and CD40 expression (n=2 $p<0.05$), an enhanced production of IL-12 and IL-1β (n=2 $p<0.05$), and decreased IL-10 (n=2 $p<0.05$). We also observed a higher ability to induce IFN-γ and TNF-α production by alloreactive lymphocytes (n=2 $p<0.05$).

Our observations support the notion that sp facilitate and might affect the early course of sexual transmission of ZIKV infection.

Key Words: Zika Virus, Dendritic Cells, Spermatozoa, Sexual Transmission

(1097) **ROLE OF *BORDETELLA PERTUSSIS* ADENYLATE CYCLASE TOXIN IN OUTER MEMBRANE VESICLES-MEDIATED IMMUNOMODULATION OF MACROPHAGES RESPONSE**

Bruno Blancá, Jimena Alvarez Hayes, Hilario Cafiero, Maria Eugenia Rodriguez
CINDEFI-CONICET-UNLP

Gram-negative bacteria produce and excrete outer membrane vesicles (OMVs) that play a role in the infection process by carrying and transmitting virulence factors into host cells, eventually modulating host defense response. *Bordetella pertussis* (Bp), the etiological agent of whopping cough, is a Gram-negative bacterium that can survive and persist inside human macrophages (MΦ). We previously showed that adenylate cyclase toxin (CyaA) is one of the factors that are involved in modulation of inflammatory host response and intracellular bacterial survival. We recently observed that OMVs released from Bp (Bp-OMVs) induce a decrease in MΦ bacterial uptake. However, once inside the cell, Bp persistence is higher in MΦ treated with Bp-OMVs, suggesting that these vesicles might mediate bacterial host defense manipulation. In the present study we evaluated the potential role of CyaA in this immunomodulatory effect of Bp-OMVs and the related increase of intracellular bacterial persistence. To this end THP-1 MΦ were treated with OMVs isolated from a Bp CyaA deficient mutant (BpΔCyaA-OMVs) or wild type strain (Bp-OMVs) and mRNA was recovered 4 h post-treatment. RT-PCR assays showed that inflammatory cytokine expression, such as IL-8 and TNF-α, was significantly higher in BpΔCyaA-OMVs treated MΦ ($p<0.05$). Accordingly, confocal microscopy studies showed that both bacterial uptake and bacterial colocalization with late endosomal/lysosomal marker LAMP-1 were significantly higher in MΦ incubated with OMVs-BpΔCyaA. In agreement with these results, we observed that the presence of CyaA in the OMVs determined a higher intracellular bacterial persistence over the time of infection. Altogether these results suggest that CyaA plays a key role in Bp host cell response modulation by OMVs and its eventual promotion of intracellular persistence.

Keywords: CyaA, OMVs, macrophages, intracellular survival, *Bordetella Pertussis.*

(1115) **HFQ IS REQUIRED FOR *Bordetella pertussis* ADAPTATION TO THE IRON STARVED HOST ENVIRONMENT**

Jimena Alvarez Hayes (1), Yanina Lamberti (1), Bruno Blancá (1), Kristin Surmann (2), Frank Schmidt (2), Maria Eugenia Rodriguez (1)
(1) CINDEFI-UNLP-CONICET, (2) University Medicine Greifswald.

Bacterial regulation of gene expression based on small noncoding RNA (sRNA) is usually involved in the response to environmental stress, such as iron starvation. Most of Gram-negative bacteria sRNA-mediated regulation requires the cofactor RNA-binding protein Hfq. It was shown that *Bordetella pertussis* (Bp) is iron starved inside its human host in which is able to survive and eventually persist inside macrophages (MΦ). As strategy to study the infective phenotype, we previously characterized Bp iron-starved proteome and showed that this environmental condition induces a remarkable shift in protein composition. Importantly, we observed that this phenotypic adaptation influences bacterial interaction with immune and epithelial cells facilitating the infectious process. In the present study, we examined the requirement for Hfq in the adaptation of Bp to iron starvation in order to evaluate its relevance in bacterial pathogenesis. By mean of shotgun proteomics we compare the iron-starved proteome of a Bp Hfq deficient mutant (BpΔHfq) with the iron-starved proteome of the wild type strain and found that 375 (out of 1325) proteins required Hfq to respond to low iron availability. Among them, we identified proteins involved in LPS and peptidoglycan biosynthesis, metabolism and transport, suggesting that Hfq plays a role in the regulation of many different pathways during Bp adaptation to iron starvation. Importantly, we observed that under this environmental condition Hfq plays a role in the regulation of the expression of several proteins critical during infection, such as iron acquisition systems, proteins involved in oxidative stress resistance and virulence factors. Accordingly, intracellular survival of BpΔHfq inside THP-1 MΦ was significantly lower than wild type bacteria ($p<0.05$), suggesting that this protein not only is important in the regulation of Bp factors involved in host colonization but also is relevant in intracellular persistence inside host cells.

Keywords: B. pertussis, Hfq, proteome, iron starvation, intracellular survival

(1141) **NOVEL GUANIDINE COMPOUND AGAINST MULTIDRUG-RESISTANT CYSTIC FIBROSIS-ASSOCIATED BACTERIAL SPECIES**

Yanina Lamberti (1), Aamed Saeed (2), Alejandra Bosch (1), Mauricio Erben (1)
(1) CINDEFI-CONICET-UNLP, (2) QUAID-I-Azam University

Chronic pulmonary infection is a hallmark of lung disease in cystic fibrosis (CF). Infections dominated by non-fermentative Gram-negative bacilli are particularly difficult to treat and highlight an urgent need for develop new class of agents to treat these infections. In this work, a small library comprising 13 novel thiourea and guanidine derivatives with low molecular weight were synthetized and studied as antimicrobial agents. The identity of the products was confirmed by FTIR, ^{1}H-NMR, ^{13}C-NMR spectra and elemental analysis. All obtained compounds were tested *in vitro* for their minimum inhibitory concentration (MIC) and their minimum bactericidal concentration (MBC) against two standard Gram negative non-fermentative bacilli species, *Pseudomamonas aeruginosa* PAO1 and *Burkholderia cenocepacia* J2315, and a panel of drug-resistant non-fermentative Gram-negative bacilli recovered from patients with CF (n=37). One novel compound, a guanidine derivative bearing adamantane-1-carbonyl and 2-bromo-4,6-difluouro-phenyl substituents (H-BDF), showed a MIC value less than 2 μg/ml against the standard strains and superior activity than the standard drugs tobramycin, ceftazimide and meropenem ($p<0.05$). Moreover, the 68.4% of clinical isolates had MICs values lower than 4 μg/ml with compound **H-BDF** whereas only 36.8%, 26.3% and 0% of isolates had MICs values lower than 4 μg/ml with meropenem, ceftazimide and tobramycin, respectively. The role that different substituents exert in the antimicrobial activity was determined, highlighting the importance of the halo-phenyl group in the guanidine moiety. Moreover, the new compound H-BDF displays low levels of cytotoxicity against THP-I cells with a selective index (SI) > 8, pointing to its potential for further development as a novel antibacterial drug.

Keywords: Antibiotics, guanidines, thioureas, resistance, cystic fibrosis

(1204) **PRESENCE OF CATHELICIDIN LL37 AND IMMUNOENDOCRINE-RELATED COMPOUNDS IN THP1-DERIVED MACROPHAGES INFECTED WITH *MYCOBACTERIUM TUBERCULOSIS* EXPOSED TO CORTISOL AND/OR DHEA**

Bettina Bongiovanni (1), Sara Marín-Luevano (2), Luciano DAttilio (1), Ariana Díaz (1), Rocío del Valle Fernández (1), María Luisa Bay (1), Bruno Rivas-Santiago (2), Oscar Bottasso (1)
(1) Instituto de Inmunología Clínica y Experimental de Rosario (IDICER CONICET-UNR), Rosario, ARGENTINA, (2) Unidad de Investigación Médica, Instituto Mexicano del Seguro Social (IMSS), Zacatecas, MEXICO

Macrophages (Mps) were found to be influenced in their anti-mycobacterial response since treatment with dehydroepiandrosterone (DHEA) of Mps infected with *Mycobacterium tuberculosis* (Mtb) led to a reduction in intracellular bacterial load and increased autophagy. On the other hand, the Mp effector response in the tuberculosis infection is highly related to the production of antimicrobial peptides such as cathelicidin LL37, whose production was found increased during autophagy, as well.

Given this background, THP-1-derived Mps were infected with Mtb strain H37Rv (MOI 5:1) during 3 h in presence or absence of cortisol (Gc, 1 and 0.1μM) and/or DHEA (1; 0.1 and 0.01μM). Upon washing, cells were cultured for 24 h in the same media with or without hormones and the expression of LL37, glucocorticoid receptors -alpha and beta- (GRα and GRβ), enzymes regulating cortisol availability (11-beta-hydroxysteroid dehydrogenase types 1 -11βHSD1- and 2), the pro-apoptotic protein caspase 3, the inflammasome-related protein 3 (NLRP3) were analyzed by qRT-PCR, and IL1β levels by ELISA.

NLRP3 and caspase 3 showed an increase in all infected cultures ($p<0.05$). –In the same sense, Mtb increased IL-1β production ($p<0.01$) and LL37 expression ($p<0.05$) respect the uninfected cultures. Treated cells with Mtb plus DHEA displayed an increase in IL1β levels ($p<0.01$) and GRα expression ($p<0.05$) compared with those only infected. Irrespective of DHEA presence, Mtb-infected cultures exposed to Gc (1μM) revealed a decreased expression of LL37 and 11βHSD1 respect the Gc-untreated counterparts ($p<0.05$). Unlike this, infected cultures subjected to combined treatment with Gc (at a lower concentration) plus DHEA showed and augmented IL-1β production ($p<0.01$) and a slightly increased LL37 expression, as compared to single Mtb-infected cells. The beneficial effect of DHEA on Mp function, which seems to be also related to LL37 production, continues to be present at low Gc doses.

(1272) **PLASMA EXPRESSION LEVEL OF miRNA IS POSITIVELY-ASSOCIATED WITH CHAGAS CARDIOMYOPATHY IN PATIENTS WITH CHAGAS DISEASE**

Silvina R Villar (1), Francisco Callejas Hernandez (2), Ana Rosa Pérez (1), Juan Beloscar (3), Oscar Bottasso (1), Manuel Fresno (2), Nuria Gironès (2)
(1) Instituto de Inmunología Clínica y Experimental de Rosario (IDICER UNR-CONICET), Rosario, Argentina, (2) Centro de Biología Molecular Severo Ochoa, (CSIC UAM), Madrid, España, (3) Cátedra y Servicio de Cardiología, Sección Chagas, Hospital Provincial del Centenario, Universidad Nacional de Rosario, Argentina

The biomarker value of circulating microRNAs (miRNAs) present in the bloodstream has been extensively studied since the discovery of these small non-coding RNA molecules that regulate gene expression. MicroRNA dysregulation has been linked to cancer development, cardiovascular and neurological diseases, lipid metabolism, and impaired immunity. Our study was designed to evaluate miRNA expression levels in individuals chronically infected with *Trypanosoma cruzi* showing different degrees of cardiac damage by Next Generation Sequencing Technologies (small-RNA-seq). Chronic chagasic patients with different degrees of cardiac involvement were classified as: Indeterminate (IND, n=5); Moderate (M, n=5) and Severe (S, n=5). Parallel sex and age-matched healthy volunteers (Co, n=5). miRNAs were extracted from human plasma using standard protocols and sequenced by Illumina MiSeq system. Finally, sequencing results were processed and analyzed by open software and databases such as Bowtie, R, samtools, ensembl. org and mirbase.org. These analyses revealed high abundance of miRNA expression in chromosome 7 in S vs Co (fold change), in agreement with previous results indicating a positive correlation between this chromosome and heart diseases. miRNASeq also showed differential expression of mature miRNAs in IND, M and S compared to Co. On the other hand, most of the smallRNA found among samples correspond to y-RNA, which has been involved in chromosomal DNA replication and cellular responses to stress, making of them new potential diagnostic biomarkers. miRNAs differentially expressed associated to heart failure (S) correspond to miRNA let-7f-5p, miRNA 125a-5p and miRNA 142-3p. Our results show an association between the presence of specific miRNA and the severity of chronic chagasic cardiomyopathy. New studies are needed for their use of follow-up and prognosis markers of the evolution of this disease.

(1317) **NOVEL IRON REGULATED ANTIGEN PROTECTS AGAINST BOTH CAUSATIVE AGENTS OF WHOOPING COUGH**

Juan Marcos Oviedo (1), Jimena Alvarez Hayes (1), Hugo Valdez (1), Juan Laborde (2), Fabricio Maschi (2), Miguel Ayala (2), María Eugenia Rodríguez (1)
(1) CINDEFI, Facultad de Ciencias Exactas, Universidad Nacional de La Plata. (2) Cátedra de Animales de Laboratorio, Facultad de Ciencias Veterinarias, Universidad Nacional de La Plata.

Whooping cough is a highly contagious infectious disease caused by Bordetella pertussis (Bp) and Bordetella parapertussis (Bpp).According to previous studies current acellular pertussis vaccine induces not only low protection against Bp. but also no protection against Bpp. New protective antigens are needed to improve the efficacy of this vaccine against both species. Through the study of proteins induced under physiological conditions, such as iron starvation-our group has identified and cloned two novel antigens protective against B. pertussis. Interestingly, the sequence of these antigens are highly conserved among both previously mentioned Bordetella species, and even more than the sequence of pertactin and FhaB, antigens included in acellular vaccines. In the present work, we studied one of this antigens (Bp1605, AfuA) as a protective immunogen against Bpp. Using western blot and ELISA tests we confirmed that Bordetella parapertussis expresses a homolog of AfuA and that, as found for B. pertussis, it is an iron regulated, surface exposed protein, expressed during infection. This study also showed that antibodies induced by immunization with the recombinant AfuA cloned from Bp (rAfuA) were able to opsonize B. parapertussis and promote bacterial uptake by neutrophils. The inefficacy of current acellular vaccines against Bpp has been attributed to the effect of the O-antigen, absent in Bp. The O-antigenhas been described as a shield that protects Bpp from antibody recognition on the bacterial surface. We here found that the O-antigen has no influence on the recognition of the antibodies raised against AfuA. Accordingly, we found that rAfuA confers protection against B. parapertussis infection in a mouse intranasal challenge model. Taken together, these results point at AfuA as an excellent vaccine candidate for a new generation of acellular vaccines protective against both whooping cough causative agents.

Keywords: Whooping cough, Bordetella parapertussis, Vaccine.

(1385) **ROLE OF PPARγ IN THE GLUCOCORTICOID-MEDIATED EFFECTS ON A MACROPHAGIC CELL LINE STIMULATED WITH *Mycobacterium tuberculosis***

Ariana Díaz (1), Rocío Del Valle Fernández (1), Bettina Bongiovanni (1), Luciano Dattilio (1), Federico Penas (2), Ágata Cevey (2), Marcela Marchesini (3), Clarisa Carmen Batistuta (3), Oscar Bottasso (1), Nora Goren (2), María Luisa Bay (1)

Tuberculosis (TB) is a major health problem characterized by an immune-endocrine imbalance: high plasma levels of cortisol and pro- and anti-inflammatory mediators (IFN-γ, IL-6, TGF-β and IL-10), with low levels of Dehydroepiandrosterone (DHEA). The etiologic agent, *Mycobacterium tuberculosis* (Mtb) is transmitted by air and captured by lung macrophages (MØ). MØ activation along with an efficient cellular immune response is required for Mtb elimination, which at the same time can mediate tissue damage. Glucocorticoids (GCs) are critical elements to counterbalance the immune-inflammatory reaction, with peroxisome proliferator-activated receptors

(PPAR) being also implicated in this regard. The main forms of these receptors are: PPARα, PPARβδ and PPARγ. TB patients showed an increased expression of the PPARγ transcript in their peripheral blood mononuclear cells, which were positively associated with disease severity of the disease and cortisol plasma levels. Given this background, we now investigated whether PPARγ contributes to the inhibitory effect of GC on inflammatory MØs response (adherent human THP-1 cells) to Mtb (strain H37Rv killed by γ radiation -Mtbi-). Stimulated MØs (n=6-8 cultures) showed increased expression of mRNA PPARγ and IL-1 levels respect the unstimulated counterparts ($p<0.05$ and $p<0.001$ respectively). Cultures exposed to Mtbi+cortisol (10^{-6}M) showed decreased levels of IL-1 compared to those only exposed to Mtbi ($p<0.001$). In addition, cells with Mtbi+cortisol plus a PPARγ specific agonist [15-deoxy-delta(12,14)-prostaglandin J2, 2μM] showed lower levels of IL-1 than those without the agonist ($p<0.01$), along with an increased expression of PPARγ transcripts ($p<0.05$). The relation between PPAR*γ* transcripts and cortisol plasma levels in TB patients together with the *in vitro* results, suggest a contribution of this receptor in the anti-inflammatory effect of GC.

(1394) **PENDRIN EXPRESSION IS AFFECTED IN EPITHELIAL AND MACROPHAGES CELLS BY *B. pertussis* INFECTION.**

Hugo Valdez, Yanina Lamberti, Juan Gorgojo, Maria Eugenia Rodiguez
CINDEFI-UNLP-CONICET

Pendrin is a transmembrane anion exchanger (encode by *SLC26A4* gene) whose expression was first described in epithelial cells and later suggested in other cells of the immune system. In the airway, pendrin mediates the uptake of Cl^- from the airway apical surface and the export of both $HCO3^-$ and thiocyanate into the airway surface liquid. The bicarbonate exported by pendrin produces an optimal pH environment for inflammatory mediators activity and favors the secretion of proteins involved in antimicrobial mechanisms in the lung. A transcriptomic study recently demonstrated the up-regulation of pendrin in mouse lung during B. pertussis (Bp) infection in a pertussis toxin-dependent (PTx) manner. Immunohistochemistry of Bp infected mice revealed pendrin expression in the lungs epithelia and possibly in macrophages. In order to gain a deeper insight into pendrin influence in Bp host infection we here examined the expression of pendrin in human bronchial epithelial cell (HBE) and human monocyte cell line (THP-1) during the Bp infection. qRT-PCR results showed that *SLC26A4* expression in HBE cells is up-regulated soon after Bpwt infection. Ptx was found involved in host cell response since the infection with a PTx deficient mutant (BpΔPtx) induced significantly lower pendrin up-regulation. On the other hand, THP1 Bp intracellular infection assays also showed a significant up-regulation of *SLC26A4* early after Bpwt infection. Again, a lower up-regulation was observed in BpΔPtx infection. As the intracellular infection progressed, however, *SLC26A4* level was found down-regulated in macrophages infected with either Bp strain as compared with uninfected cells showing that this pathogen is able to modulate this response in a PTx independent manner. Altogether these results suggest that pendrin might contribute to host defense response during Bp infection but also show that Bp is able to manipulate its expression in macrophage during the development of intracellular infections.

Keywords: Pendrin, Bordetella pertussis, epithelial cells, THP-1 cells

(1397) **ANTIBODIES AGAINST FIMBRIAL SUBUNITS INCLUDED IN ACELLULAR VACCINES DO NOT HAVE BIOLOGICAL ACTIVITY AGAINST *Bordetella parapertussis***

Juan Pablo Gorgojo, Juan Marcos Oviedo, Maria Eugenia Rodriguez
CINDEFI - UNLP – CONICET.

Resurgence of whopping cough is partially due to an increase in the incidence of *B. parapertussis* (Bpp) infections whose start concurs with the replacement of whole cell vaccines by acellular vaccines (AV). AV are formulated with *B. pertussis* (Bp) antigens some of which are homologous to those produced by Bpp. Previous studies, however, showed that most antibodies induced by AV fail to protect against Bpp due to the presence of the O antigen (AgO) on the Bpp surface that impairs antibody access to shared antigens. However, controversial results have been reported regarding the role of AV induced anti-fimbria antibodies against Bpp. Fimbriae are proteins exposed on the surface of Bpp and due to its length it is very unlikely shielded by the AgO. Antibodies against these antigens have shown to be protective against Bp but little is known about the cross protection induced by Bp fimbrial subunits 2 and 3 (Fim2/3) against Bpp. In this study we examined the potential of Fim2/3 as vaccine antigens against Bpp infections. To this end, the biological activity of antibodies induced by a vaccine formulated by Bp Fim2/3 was evaluated against Bpp. Whole cell ELISA showed that anti-Fim2/3 antibodies poorly recognize Bpp. Functional assays showed that these antibodies do not agglutinate Bpp and fail to inhibit Bpp attachment to epithelial cells. The AgO was found not involved in the absence of antibody recognition, agglutination activity or inhibition of Bpp attachment to epithelial cells, as determined by the use of an AgO mutant. Proteomic studies showed that Bpp do not express Fim2/3 and bioinformatics analysis suggested that the lack of biological activity of anti-Fim2/3 antibodies against Bpp might be due to a low degree of homology with Bpp fimbriae. Together with previous results this study demonstrates that none of the components of current acellular vaccines protect against Bpp stressing the need for a new generation of preventive strategies to control whooping cough.

Keywords: Bordetella parapertussis, acellular vaccine, fimbriae, fimbrial subunits, protection.

TOXICOLOGY 1

(102) **BISPHENOL S (BPS) INDUCES STRUCTURAL AND MOLECULAR ALTERATIONS IN UTERUS AND OVARIES IN A RAT MODEL OF PCOS**

Brenda Demacopulo (1, 2), Carolina Canessa (1, 3), Ailen Fidyka (1, 3), Noelia Zamora (1, 3), Romulo Luis Cabrini (1, 4), Erica Lorena Kreimann (1, 2)
(1) Departamento de Radiobiología, Comisión Nacional de Energía Atómica (CNEA). (2) Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET). (3) Universidad CAECE. (4) Facultad de Odontología UBA.

Bisphenol A or (BPA) is the most common component of polycarbonates and it has toxic effects in the reproductive system. In order to reduce BPA exposure, the use of alternative compounds such as *Bisphenol S (BPS)* has been proposed. Unfortunately, BPS also displayed estrogenic, antiestrogenic, androgenic and antiandrogenic actions. Therefore, there is a growing concern about the biological effects of BPS in terms of toxicity, genotoxicity, endocrine disruption and neurobiological levels**.**

Objectives: To study the effect of BPS in the uterus and its role in ovarian cysts development in a known rat model of PCOS.

Materials and Methods: Immature Wistar rats (21-22 days old) were injected with vehicle, dehydroepiandrosterone or DHEA (60 mg/kg), DHEA+BPS and BPS alone (1 ug/kg) for 20 days. Tissues were stained with hematoxylin-eosin (H&E) and immunohistochemistry. Statistical differences were evaluated by the Student T-Test.

Results: BPS induces alterations in uterus such as an increase in tissue elasticity and vacuolization of endometrial cells. The administration of BPS in DHEA treated rats, increased significantly the percentage of vacuolization of the endometrial layer (DHEA/BPS 68.77%±17.87 compared to DHEA: 40.29%±19.06, $p<0.001$, n=10 and 9). At the molecular level, we found changes in the expression pattern of the protein Ezrin which is has been involved in cancer progression and metastasis. DHEA-BPS administration increased the citoplasmatic accumulation of EZRIN in the epithelium of endometrial glands compared with DHEA treated animals (97.88%±18.32 vs. 41.38%±5.62, $p<0.001$, n=10 and 10). In ovaries, BPS administration altered the number of structures such as cysts, precysts, and type III follicles induced by DHEA alone, $p<0.001$).

Conclusion: In summary, our work would show that low doses of BPS induce morphological and molecular changes in the uterus and ovaries of rats bearing a PCOS condition.

3-Methylcholanthrene (3MC), a polyaromatic hydrocarbon, is an environmental pollutant that causes reproductive toxicity and genotoxicity. Previous studies showed that 3MC alters the ovarian function by affecting the follicle integrity in rodents, and causes DNA damage in peripheral blood, bone marrow and oocytes. Now, we studied the effect of daily exposure to 3MC on the oocyte integrity, induction of chromosome aberrations in bone marrow and the ability of alpha-naphthoflavone (**αNF**) to prevent this action. To this end, immature rats were daily injected with a combination of 3MC (0.1 and 1 mg/kg) and αNF (80 mg/kg) for 20 days. Oocyte integrity by morphological parameters, expressed in **µ**m; oocyte viability by fluorescence dyes; and chromosome aberrations (CA) in bone marrow cells were evaluated. All data are expressed as mean±SEM and all statistical analysis were performed by two-way ANOVA with Bonferroni post-test. Levene's test and a modified Shapiro-Wilk test were used to assess homogeneity of variances and normal distribution, respectively. Compared with controls (C), both doses of 3MC increased the area (C 12.42±0.18; 3MC 14.51±0.64; P<0.001), perimeter (C 77.20±0.89; 3MC 96±2; P<0.001): and perivitelline space of oocytes (C 1.61±0.06; 3MC 2.29±0.09; P<0.001) and decreased both the thickness of the zona pellucida (C 1.69±0.06; 3MC 1.13±0.04; P<0.001) and the number of viable oocytes (C 86%±2; 3MC 60%±3; P<0.001). Likewise, 3MC-treated rats, at both doses, exhibited a higher number of CA (C 7%±2; 3MC 19%**±4; P<0.001)**, especially in the number of metaphases with dicentric chromosomes (C 2.40%±0.52; 3MC 8%±2; P<0.001) and fragments of chromosomes (C 0.97%±0.45; 3MC 3.59%±0.38; P<0.001). All these changes were prevented by daily treatment with αNF. In conclusion: i) daily exposure of 3MC alters the oocyte integrity; ii) low doses of 3MC are enough to induce chromosome aberrations in bone marrow; and iii) αNF prevents both the systemic and oocyte toxic effect of 3MC.

Key words: 3-methylcholanthrene, alpha-naphthoflavone, oocyte, bone marrow.

(1297) **TI(I) AND TI(III) PREVENT PC12ADH CELL PROLIFERATION**

Damiana Maria Salvatierra Fréchou, Melisa Debora Potap, Pablo Julio Schwarzbaum, Sandra Viviana Verstraeten
Department Of Biological Chemistry, IQUIFIB, School Of Pharmacy And Biochemistry, UBA, Argentina

Thallium (Tl) induces apoptosis in PC12 cells. However, in a PC12 cell adherent variant (PC12adh), this effect was not observed, although a potential cytotoxic effect of Tl on this cell line could not be discarded.

MTT reduction, evaluated in PC12adh cells incubated in the presence of 10-100 μM Tl(I) or Tl(III) (24-72 h), was significantly decreased after 24 h of cell exposure. Tl did not cause cell necrosis, as evaluated from LDH release or nuclear staining with acridine orange and ethidium bromide. To evaluate if Tl could alter PC12adh cell proliferation, the number of cells was estimated by Trypan blue staining. In control samples, the number of cells increased linearly with time. In contrast, in 100 μM Tl-treated samples the amounts of cells remained constant after 48 h of exposure, and were markedly lower than those of the controls (two-way ANOVA). By using specific inhibitors, we observed that Tl did not affect ERK-, mTOR-, PLC-, PKC-, and p53-dependent proliferative pathways. In contrast, inhibition of PI3K enhanced Tl-dependent prevention of cell proliferation, suggesting that this pathway could partially counteract the effects of Tl. Cell cycle analysis by flow cytometry indicated that both Tl(I) and Tl(III) caused partial arrest of the cycle in G2/M phase, without affecting S phase. Accordingly, the amounts of cells in G0/G1 phase decreased with the time of exposure to Tl. Cell volume (forward scatter) and internal complexity (side scatter) also increased with time, in accordance with the appearance of intracellular vacuoles. Tl did not cause cell senescence, indicated by the lack of activation of senescence-associated β-galactosidase. Together, present results suggest that both Tl(I) and Tl(III) prevent PC12adh cell proliferation, and the signaling pathways affected by these cations remain to be elucidated.

(1627) **EFFECT OF CADMIUM BIOTOXICITY AND SOY PROTEIN DURING RAT GESTATION**

Veronica Biaggio, Maria Sofia Gimenez
Laboratorio de Nutrición y Medio Ambiente - IMIBIO - Conicet - Universidad Nacional de San Luis

Introduction: the placenta is the main known tissue to protect the fetus from environmental toxins, such as cadmium (Cd). This divalent ion is a cytotoxic endocrine disruptor and produces an imbalance in the transport of nutrients through the placenta, thus causing a decrease in fetal birth weight or premature births. Several studies show that at very low doses, Cd can induce fetal growth restriction, thus increasing the risk of neonatal morbidity and mortality or generating in adult life diseases such as diabetes, obesity or coronary heart disease.

Soy protein is becoming increasingly important in the human diet. Santell et al. (1997) demonstrated that isoflavones (genistein) could cause hypertrophy in the rat endometrium and alter reproductive function in numerous species. Objective: to evaluate the possible protective role of the consumption of soy protein compared to the mechanisms by which Cd exerts its toxicity. Materials and Methods: 4 lots of female Wistar rats were used: 2 lots received casein (Cas) and 2 lots soybean (Soy) as protein source. Within each group, 1 lot received regular water (control-Co) and the other, 15 ppm of Cd in the drinking water during pregnancy period (20G). Results: We determined TBARS, catalase (CAT) and glutation peroxidase (GPx) activity, and nitrite concentration. Placenta tissue total RNA was extracted and RT-PCR was performed using the following primers: MT I; MT II; Nrf-2; NOX-2, SOD-2 and CAT. The concentration of Cd increased in both intoxicated groups ($p < 0.001$). In Soy-Cd group GPx activity; the levels of MDA, nitrite and expression of Nrf-2; SOD and MT I increased ($p < 0.05$, $p < 0.001$, $p < 0.05$, $p < 0.05$, $p < 0.01$ and $p < 0.001$). While CAT activity; expression of mRNA NOX-2 and MT II decreased ($p < 0.01$, $p < 0.01$ and $p < 0.001$).

Conclusion: these results would indicate the presence of an oxidative and nitrosative environment, in placenta at 20G, which would suggest possible alterations in the embryonic development.

(638) **HEXACHLOROBENZENE EXPOSURE INDUCES CELL MIGRATION, INVASION AND ANGIOGENIC FACTORS EXPRESSION IN HUMAN ENDOMETRIAL STROMAL CELLS**

(3) CONICET-Universidad de Buenos Aires, Centro de Estudios Farmacológicos y Botánicos (CEFYBO), Laboratorio de Fisiopatología Placentaria, Buenos Aires, Argentina.

Endometriosisis is an invasive gynecological disorder of reproductive women characterized by the growth of endometrial glands and stroma outside the uterus. The disease is associated with chronic pelvic pain, dysmenorrhea, and infertility. Exposure to en-

docrine-disrupting environmental pollutants could play a role in the disease etiology. Hexachlorobenzene (HCB) is an organochlorine pesticide found in maternal milk and in lipid foods, that induces toxic reproductive effects in laboratory animals. Degradation of extracellular matrix by metalloproteinases (MMPs) is a basic step in migration and invasiveness in endometriosis. Recently, we demonstrated that HCB enhances cyclooxygenase (COX-2) expression, MMP2 and 9 activation and prostaglandin E2 secretion in human endometrial stromal cells. Pathological angiogenesis is the hallmark of endometriosis. The pro-angiogenic factor, such as vascular endothelial growth factor (VEGF) in the peritoneum of endometriosis patients supports the growth of the ectopic implants. The present study examined the effect of HCB in human endometrial stromal cell line T-HESC on cell migration (scratch motility assay), cell invasion (transwell Matrigel invasion assay), and expression of angiogenic factor VEGF (WB). Cells were exposed to HCB (0.005, 0.05, 0.5 and 5 μM) or vehicle for 24, 48 or 72h. Results showed that the pesticide increased cell migration (47%, $p<0.05$; 81%, 77% and 96%, $p<0.001$) in a dose response manner and through of aryl hydrocarbon receptor (AhR), COX-2, c-Src and estrogen receptor. Moreover HCB (0.5 μM) induced the invasiveness potential of T-HESC (200% $p<0.05$). VEGF secretion was induced by HCB (0.005-0.05 μM) (130-150%, $p<0.05$), while VEGF intracellular content was decreased at HCB (0.05-0.5 μM) (40-60%, $p<0.05$). Our results indicate that HCB exposure could contribute to maintenance and development of endometriosis promoting cell migration, invasion, and angiogenic factors secretion in human endometrial cells T-HESC.

Glyphosate exposure during critical periods of development induced adverse effects on the reproductive system of male rats, suggesting an endocrine disruption action. In addition, we have shown that the male rat mammary gland is susceptible to endocrine disruption. Here, we evaluated whether perinatal exposure to a glyphosate based herbicide (GBH) alters the mammary gland morphology and endocrine response in postpubertal male animals. Pregnant rats were exposed orally through the diet to vehicle (saline solution), 350 or 3.5 mg/kg/day of GBH from gestational day 9 until weaning. On postnatal day 60, the male offspring were sacrificed and mammary gland and blood samples were collected. Testosterone (T) and estradiol (E) serum levels were measured and, total area, perimeter, longitudinal growth and mammary density were analyzed in mammary gland whole-mounts (WMs). Relative epithelial area, estrogen (ESR1) and androgen receptor (AR) protein expression and proliferation index were also evaluated in histological sections. T and E serum levels were similar between groups; however, the exposure to GBH350 increased the longitudinal growth and reduced the mammary density, without modifying the total area or perimeter of the mammary gland. In accordance with these results, the proliferation index, relative epithelial area and ESR1 expression were also reduced in GBH350-exposed animals, whereas no difference was detected in AR expression. On the other hand, GBH3.5-exposed animals presented similar WM and histological parameters to controls rats. Also, in this last group, ESR1 expression was decreased and AR levels were increased, without altering the proliferation index. Our results demonstrate that perinatal exposure to GBH alters the morphology of the male rat mammary gland long after exposure ended and suggest that the effects may be due to an altered ESR1 expression.

Keywords: Male, Mammary Gland, glyphosate based herbicide

NEONATAL EXPOSURE TO A GLYPHOSATE-BASED HERBICIDE ALTERS UTERINE ADENOGENESIS IN EWE LAMB.

(1) Instituto de Salud y Ambiente del Litoral (ISAL), Facultad de Bioquímica y Ciencias Biológicas, CONICET-Universidad Nacional del Litoral, (2) Instituto de Investigación Agropecuaria, Ambiente y Salud (IIPAAS), Facultad de Ciencias Agrarias, Universidad Nacional de Lomas de Zamora

Abstract: Glyphosate based herbicides (GBH) are one of the most extensively used pesticides in agriculture all over the world. Recently, we showed that a brief exposure to a GBH during the first week of life alters uterine development and induces epithelial hyperplasia in prepubertal rats, and causes post-implantation embryo loss at adulthood. This study investigates the effects of a brief postnatal exposure to a low dose of GBH on the differentiation of the prepubertal ewe lamb uterus. Ewe lambs (Frizone breed) were sc injected from postnatal day 1 (PND1) to PND14 with saline solution (vehicle) or 2 mg/Kg/day of a GBH (reference dose from EPA, USA). On PND45 ewe lambs were hysterectomized and uterine samples were paraffin-embedded or stored at -80°C until mRNA extraction. Cell proliferation was assessed in all uterine compartments by quantifying the expression of Ki-67 protein through immunohistochemistry (IHQ). We also determine the uterine expression of Forkhead box A2 (Foxa2) protein by IHQ, which is involved in the uterine gland development. RT-PCR was performed to evaluate the expression of IGF family genes related with the cell proliferation, i.e., insulin-like growth factor-1 (IGF-1), IGF-2 and its receptor (IGF-1R). GBH treatment decreased the proliferation rate in the subepithelial stroma (7.7±0.9% vs C:12.2±1.5%, $p<0.05$) and in the luminal (7.7±1.1% vs C:16.1±1.1%, $p<0.005$) and glandular epithelium (10.8±0.8% vs C:20.6±2.0%, $p<0.005$). This alteration could not be associated with a deregulation of the IGF pathway, since no changes were detected in gene expression. Foxa2 expression, which is only detected on the glandular epithelial cells, was decreased on the GBH exposed group (2.3±0.4 vs C:3.8±0.6, $p<0.05$). Postnatal exposure to a low dose of a GBH disrupts the uterine development of prepubertal sheep, by decreasing cell proliferation and altering the expression of Foxa2 involved in uterine adenogenesis. These alterations might affect female fertility at adulthood.

(803) **NEONATAL EXPOSURE TO A GLYPHOSATE-BASED HERBICIDE DISRUPTS ANGIOGENESIS IN UTERINE DECIDUALIZATION IN PREGNANT RATS**

Paola Inés Ingaramo (1), Jorgelina Varayoud (1), María Mercedes Milesi (1), Ramiro Alarcón (1), Mónica Muñóz-de-Toro (1), Enrique Hugo Luque (1)

(1) Instituto de Salud y Ambiente del Litoral - UNL – CONICET.

The glyphosate-based herbicides (GBH) are commonly used to control weeds. Recently, it has been shown that neonatal treatment of Wistar rats with GBH alters the uterine development. These rats have reproductive problems as post-implantation failure associated with diminished decidualized area of implantation sites (IS). The aim of present work was to evaluate if decidualization failure in GBH-exposed rats could be caused by defective uterine angiogenesis. Female Wistar pups received saline solution (control, C) or an environmentally relevant dose of GBH (2 mg/kg) by sc. injection on postnatal day (PND) 1, 3, 5 and 7. On PND90 females were mated with fertile males non-exposed to GBH. Pregnant rats were sacrificed on gestation day 9 (GD9) to evaluate angiogenesis process in the IS. The newly formed blood vessels were detected by nestin immunostaining. The mRNA expression of VEGF and NOTCH1 were quantified using qRT-PCR. Macrophages were detected by immunohistochemistry and the results were expressed as volume den-

sity. GBH-exposed rats showed an increase of macrophages in the decidua, specifically in the antimesometrial zone (C: 1.2±0.1% vs GBH: 1.7±0.2%, $p<0.05$). In addition, nestin positive area decreased in GBH-exposed rats (C: 2.9±0.5% vs GBH: 1.6±0.3%, $p<0.05$). Furthermore, the mRNA expression of two angiogenic regulators VEGF and NOTCH1 was decreased in GBH-exposed rats (C: 55±3% vs GBH: 23±5% and C: 21±2% vs GBH: 12±2%, $p<0.05$, respectively). Present results demonstrate that the neonatal exposure to GBH interferes with the mechanism involved in vascular adaptation during decidualization process. The recruitment of macrophages could evidence an inflammatory process linked to decreased angiogenesis during decidualization that might be responsible for the reproductive failures found in neonatal GBH-exposed rats.

(3) Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Laboratorio de Radioisótopos, Buenos Aires, Argentina.

Hexachlorobenzene (HCB) is an organochlorine compound found in maternal milk and in lipid foods. Chlorpyrifos (CPF) is an organophosphate pesticide used for pest control in agriculture. Breast cancer is by far the most frequently diagnosed cancer in women. HCB and CPF act as endocrine disruptors stimulating cell proliferation in different breast cancer models. Vascular endothelial growth factor (VEGF) and cyclooxygenase-2 (COX-2) promote tumor proliferation and angiogenesis. Nitric oxide (NO) and abnormal expression of nitric oxide synthases (NOS1, NOS2, NOS3) are implicated in cancer biology and tumor progression. We examined the action of HCB and CPF on angiogenesis in mammary carcinogenesis *in vivo* and *in vitro*. In a xenograft model with MCF-7(+ERα), HCB (3 mg/kg bw) and CPF (0.1 mg/kg bw) stimulated angiogenic switch (number of vessels/mm^2) (HCB $p<0.01$; CPF $p<0.05$) and increased VEGF expression by WB ($p<0.01$) in mice skin. In MCF-7, HCB (0.005μM) at 3h increased NOS1 ($p<0.05$) and NOS3 ($p<0.01$) levels by WB, while HCB (5μM) at 24h decreased NOS1 and NOS3 expression ($p<0.05$; $p<0.01$). Furthermore, both doses of HCB increased NOS2 levels at 3h ($p<0.05$) while HCB (5μM) decreased such levels at 24h ($p<0.05$). HCB also increased COX-2 and VEGF levels at both doses at 24h ($p<0.01$). CPF (50μM) increased NOS3 ($p<0.01$) and VEGF expression ($p<0.05$), while 0.05 and 50μM increased COX-2 levels at 24h ($p<0.05$; $p<0.01$). Exposure to each pesticide enhances the production of NO (0.005μM HCB at 3h, $p<0.05$, while 0.05μM CPF at 24h, $p<0.01$). Our results demonstrate that both pesticides increase angiogenesis and VEGF expression in a xenograft model and in MCF-7 cell line. At low doses, that induces proliferation, we observed an enhance in NOS expression and NO production, while at high doses that promotes apoptosis, we found a reduction in NOS expression and NO content in MCF-7 cells. Our findings suggest that HCB and CPF may be a risk factor for human breast cancer progression.

Keywords: Angiogenesis, breast cancer, hexachlorobenzene, chlorpyrifos.

(1029) **THE ARYL HYDROCARBON RECEPTOR AGONISTS REACTIVATE LINE-1 RETROTRANSPOSON IN BREAST CANCER CELLS**

Noelia Victoria Miret (1), Daniel Zappia (2), Lorena Zarate (1), Carolina Pontillo (1), Florencia Chiappini (1), Marianela Lasagna (3), Claudia Cocca (3), Federico Monczor (2), Andrea Randi (1)

(1) Universidad de Buenos Aires, Facultad de Medicina, Departamento de Bioquímica Humana, Laboratorio de Efectos Biológicos de Contaminantes Ambientales, Buenos Aires, Argentina, (2) Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Instituto de Investigaciones Farmacológicas (UBA-CONICET), Laboratorio de Farmacología de Receptores, Buenos Aires, Argentina, (3) Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Departamento de Físico-Matemática, Laboratorio de Radioisótopos, Buenos Aires, Argentina.

Breast cancer is the most common cancer worldwide in women and Argentina is the second country of America with the highest mortality rate. Epigenetic changes are more frequent in breast cancer cells than genetic mutations. These alterations affect retrotransposons like the long interspersed nuclear element 1 (LINE-1), which is highly activated in breast tumors. Environmental pollutants ligands of aryl hydrocarbon receptor (AhR) can induce the activation of LINE-1 and epithelial to mesenchymal transition, through the transforming growth factor-β1 (TGF-β1)/Smad signaling pathway. AhR is a transcription factor that modulates processes such as apoptosis, proliferation and migration. We worked with environmental doses of two weak ligands of the AhR: the organochlorine pesticide hexachlorobenzene (HCB) and the organophosphate chlorpyrifos (CPF). Our aim was to study the effect of these pesticides on LINE-1 expression and to elucidate whether the mechanism of action is related to the interaction AhR/TGF-β1, in the human breast cancer cell line MDA-MB-231 (- estrogen receptor α). We have reported that HCB (0.005, 0.05, 0.5 y 5 μM) activates the AhR/c-Src signaling, which subsequently induces the TGF-β1/Smad pathway, promoting MDA-MB-231 cell migration and invasion. Our results showed that LINE-1 mRNA levels, evaluated by RT-qPCR, were enhanced at 0.005 μM HCB ($p<0.01$), but reduced at 5 μM HCB ($p<0.05$) after 24 h. On the other hand, CPF (0.05, 0.5, 5 y 50 μM) increased LINE-1 mRNA content after 48 h ($p<0.01$). Western blot results showed that CPF (0.5 μM) enhanced AhR protein expression ($p<0.05$) at 24 h, as well as c-Src ($p<0.05$) and Smad 2/3 ($p<0.01$) phosphorylation after 15 and 30 min. In conclusion, we demonstrated that these pesticides modulate LINE-1 expression in MDA-MB-231, depending on the dose and the time of exposure. These findings could be linked to alterations previously observed in process like breast cancer cell proliferation, migration or invasion.

Keywords: LINE-1, HCB, CPF, breast cancer.

(1518) **CYSTIC FIBROSIS TRANSMEMBRANE REGULATOR (CFTR) IN HUMAN TROPHOBLAST HTR8/SVNEO CELLS MODULATES SEVERAL PROCESSES OF PLACENTATION**

Gabriela Marino, Alejandra G. Palma, María Fernanda Rubio, Basilio A. Kotsias, Mónica A. Costas

Laboratorio de Canales Iónicos; Laboratorio de Apoptosis y Biología Molecular. Instituto de Investigaciones Médicas Alfredo Lanari, UBA-CONICET.

The expression of different channels and transporters is altered in preeclamptic placentas, including the cystic fibrosis regulatory channel (CFTR), and defective placentation is one of the main features of this gestational disorder.

Our aim was to study the expression and participation of placental CFTR in the proliferation, migration, invasion and apoptosis during placentation.

We observed by Western blot in first trimester extravillous trophoblast cell line (HTR8/SVneo) the typical band of ~160 KDa of CFTR. The silencing of the CFTR with a specific siRNA (50nM) showed a half decrease channel expression compared to control without treatment and the scramble at 48-72h ($p<0.05$, n=4). Expression and localization of the channel was confirmed by immunocytochemistry. The silencing of CFTR by siRNA resulted in the inhibition of ~30% of cell viability at 72h ($p<0.05$, n = 5) by MTT assay and similarity

decreased cell viability by Trypan blue exclusion technique ($p<0.05$, $n = 3$). We evaluated CFTR participation in the migratory capacity of the cells by wound healing assay at 5-6h. We found that cells with the CFTR siRNA covered a smaller area of the wounds (13.6±2.0%) than with the scramble (40.9±2.5%) or with the control (38.8±1.5%) ($n =9$, $p <0.05$). Matrigel-based invasion assay showed that cell invasion ability was significantly attenuated when a CFTR siRNA was used, compared to control and scramble groups ($p<0.05$, $n=3$). After staining the cells with AO and Et/Br, apoptosis cells (orange cells) were observed under the fluorescence microscope. The apoptotic percentage was increased in cells CFTR siRNA treated (46.0±6.5%) with respect to control (19.0±3.3%) and scramble (21.0±3.5%) after of the addition of peroxide for 24h ($p<0.05$, $n=12$).

We conclude that CFTR is present in HTR8/SVneo cells and participates in the proliferation, migration, invasion and apoptosis of these cells, suggesting that alterations in CFTR may be related to an abnormal placentation.

(736) **MODULATION OF CISD1 EXPRESSION BY THE ACTIVITY OF THE CFTR CHANNEL**

Consuelo Mori, Mariángeles Clauzure, María M. Massip-Copiz, Ángel G. Valdivieso, Tomás A. Santa Coloma
Instituto de Investigaciones Biomédicas (BIOMED) UCA-CONICET.

Cystic fibrosis (CF) is a frequent autosomal recessive disease caused by mutations that impair the CF transmembrane conductance regulator (CFTR) protein function, which indirectly affect the expression of a net of genes. We described a new CFTR-dependent gene downregulated in CF cells, CISD1, also referred to as mitoNEET, encoding for the first member of a family of proteins possessing a CDGSH signature. CISD1 is a dimeric mitochondrial outer membrane protein, implicated in many facets of human pathophysiology, but its molecular function remains poorly characterized. We have previously described that *CISD1* gene expression was decreased in a CF cellular model and restored in the same cells ectopically expressing wt-CFTR (CFDE and CFDE/6RepCFTR cells). Now we used another cellular model, human colon adenocarcinoma T84 cells, and by real-time PCR we determined that *CISD1* gene expression was decreased in T84 cells treated with CFTR(inh)172, compared to control cells ($p<0.05$). These results confirmed that CISD1 expression is decreased in CF cells or in cells with impaired CFTR function. We are now studying the possible mechanisms involved in this regulation. Recently, we also report an elevated expression of diverse cytokines in CF cells in culture, including IL-1β. We have previously shown that IL-1β (>2.5 ng/ml) inhibit CFTR mRNA expression in T84 cells. Here we show that externally added IL-1β (5 ng/ml) reduces the CISD1 mRNA expression. Moreover, treatments with IKK inhibitor II (NF-κB pathway) increased the CISD1 mRNA expression. In conclusion, *CISD1* gene expression is decreased in cells with impaired CFTR function. Similar effects were obtained when exogenous IL-1β was added. These results suggest that IL-1β acts as a bridge connecting the CFTR with the CISD1 expression.

The CFTR protein is a cAMP-regulated chloride channel. By using differential display, we have found previously several CFTR-dependent genes, including c-Src, MUC1, MTND4 and CISD1. We also reported the existence of chloride-dependent genes, such as GLRX5 and RPS27. Here, using nigericin and tributyltin to clamp the pH and the intracellular chloride concentration $[Cl^-]_i$ of IB3-1 epithelial cells, we show that IL-1β is also a Cl^--dependent gene that can be modulated by changing the intracellular chloride concentration, in a biphasic way. The IL-1β secretion measured by ELISA also showed a similar pattern of response to changes in $[Cl^-]_i$. The mechanism involves an IL-1β autocrine effect, since in the presence of the IL-1β receptor antagonist IL1RN and anti-IL-1β blocking antibody, Cl^- effects disappeared ($p<0.05$, $n=3$). Similar effects were obtained with the JNK inhibitor, c-Src inhibitor and the IKK inhibitor, suggesting that JNK, c-Src and NF-kB are important mediators of the $[Cl^-]_i$ signaling. Moreover, studying the inflammasome complex by real-time PCR and Western Blot techniques, we found that caspase-1 and NLRP3 expression mRNA and protein was modulated by Cl^- ($p<0.05$, $n=3$). Interestingly, ASC expression is not affected by Cl^-. Inhibitors of caspase-1 or NLRP3 inflammasome abolish the Cl^- stimulation ($p<0.05$, $n=3$), suggesting that Cl^- can modulate the NRLP3 inflammasome. In conclusion, the Cl^- anion act as a second messenger for CFTR, modulating the expression of NLRP3 inflammasome and the resulting secretion of IL-1β, through an autocrine IL-1β loop that involves IKK and JNK kinases. This work was supported by the ANPCYT (grant numbers PICT 2012-1278 and PICT-2015-1031), CONICET (grant PIP 11220150100227CO 2015-2017 and PUE 22920160100129CO), and UCA; also by research fellowships from CONICET.

Keywords: CFTR, Chloride, IL-1β, Caspase-1, NLRP3.

(1745) **HIV-1 TAT PROTEIN DISTURBS THE SIGNALING CASCADE THAT LEADS TO ACROSOMAL EXOCYTOSIS IN HUMAN SPERM**

Anahí Belén Pacheco Guiñazú (1), Diego Masone (1), Bruno Beaumelle (2), Lucas Resa (1), Karina Altamirano (1), Silvia Belmonte (1)
(1) Instituto de Histología y Embriología Mendoza-CCT-CONICET. FCM, UNCuyo. (2) CNRS, UMontpellier2, France.

The acrosome reaction (AR) is a regulated calcium-dependent exocytosis necessary for fertilization. Fertility parameters in HIV-seropositive men are abnormal. The HIV-1 transactivating protein (Tat) is released by infected cells and extracellular Tat enters uninfected cells by endocitosis inducing toxic effects. This protein impairs neurons secretion contributing to HIV pathogenesis. The aim of this work was to determine if HIV-1 Tat was able to enter a non-endocytic cell like sperm affecting gamete function. First, we incubated spermatozoa with recombinant wild type Tat (WT-Tat). By WB and indirect immunofluorescence, we demonstrated that Tat, at physiological concentrations, pass through human sperm membranes.To elucidate the mechanisms involved in Tat internalization we challenged sperm with Tat mutants. We observed that a W11 residue is required in this process. WT-Tat strongly impaired progesterone (Pg)-induced AR as measured by exocytosis assays. Considering that HIV-1 Tat binds phosphatidylinositol (4,5)-bisphosphate (PIP_2) with high affinity and that our laboratory has shown that PIP_2 plays a key role in the sperm exocytic cascade we tested a Tat mutant unable to bind PIP_2. As expected, the mutant did not affect sperm exocytosis. To confirm that the inhibitory effect of Tat on the AR is due to its ability to bind the phospholipid, we rescued Tat-induced inhibition of secretion by adding PIP_2. This suggests that Tat is sequestering PIP_2. We assumed that Pg-induced AR inhibition will occur due to lack of IP_3 synthesis. To test this argument, we resorted to the agonist of IP_3 receptors, adenophostin that rescued Pg-induced exocytosis after Tat inhibition. These findings suggest that Tat requires the W11 residue to permeate through the plasma membrane and when inside the sperm a strong interaction with PIP_2 avoids the AR to proceed. Our findings may provide some clues to elucidate the unsolved issues concerning to male fertility in HIV patients.

(1629) **DNAJC5 Y HSC70 ARE PRESENT AND NECESSARY FOR ACROSOMAL EXOCYTOSIS IN HUMAN SPERM**

Karina Flores Montero (1,2), María Victoria Berberián (2), María Celeste Ruete (1)
(1) Instituto de Histología y Embriología "Dr. Mario H. Burgos". (2) Facultad de Ciencias Exactas y Naturales (FCEN).

Calcium-triggered exocytosis, which releases neurotransmitters and hormones into the extracellular medium, is a key cellular event mediated by the fusion of large and dense secretory granules with the plasma membrane.

The sperm acrosome reaction (AR) is a unique, regulated exocytosis with special characteristics that plays a central role in the fertilization process. The human sperm possesses a single, large, flat granule that is released during AR. Acrosomal exocytosis involves the opening of a large number of fusion pores, merging the outer acrosomal and plasma membranes. In this process, the monomeric SNARE proteins are assembled into *trans* complexes, causing the irreversible docking of these membranes (acrosome and plasmatic). The fusion-competent conformation of the SNARE proteins and the SNARE-complex assembly are maintained by molecular chaperones.

Molecular chaperones DnaJC5 and Hsc70 have been reported to facilitate the correct folding of polypeptides and to regulate the assembly of protein complexes involved in neurons and neuroendocrine cells exocytosis. However, the role of these chaperones in sperm remains unknown. Our goal is to determine the presence, localization and the role of these molecular chaperones in the assembly of *trans*-SNARE complexes in acrosomal exocytosis.

By western blot, immunofluorescence and electronic microscopy, we show that both DnaJC5 and Hsc70 proteins are present in human sperm. Besides, we demonstrate that DnaJC5 is predominantly membrane bound, whereas Hsc70 is cytosolic. Moreover, by functional assays, using anti-DnaJC5 or anti-Hsc70 antibodies, we show that they are functionally active in secretion since they inhibited AR in a concentration-dependent manner. These results therefore assist in our understanding of the role of DnaJC5 and Hsc70 in acrosomal exocytosis.

(628) **ESTRADIOL EFFECTS ON LEPTIN EXPRESSION IS MEDIATED BY THE INTERRELATIONSHIP OF DIFFERENT TRANSCRIPTIONS FACTORS.**

Malena Schanton (1), Maria Fernanda Camisay (1), Antonio Peréz Peréz (2), Bernardo Maskin (3), Victor Sanchez Margalet (2), Alejandra Giselle Erlejman (1), Cecilia Varone (1)
(1) Departamento de Química Biológica, FCEN, UBA, IQUIBICEN, CONICET, Buenos Aires, Argentina. (2) Departamento de Bioquímica Médica y Biología Molecular, Universidad de Sevilla, Sevilla, España. (3) Hospital Nacional Profesor Alejandro Posadas, Buenos Aires, Argentina.

Leptin is a key hormone in placental physiology. It regulates trophoblast proliferation, inhibits apoptosis, stimulates protein synthesis, and regulates fetal growth and development. The mechanisms involved in the regulation of placental leptin expression are not fully understood. Previous results from our lab demonstrated that estradiol (E_2) regulates leptin expression involving genomic and non-genomic effects. In these study we aimed to analyze the effect of Sp1 and NFκB transcription factors and cAMP/PKA signaling pathways in the induction of leptin expression by E_2 in human placental cells. BeWo cells cultured under standard conditions, as wells as human placental explants were used. Western blot, *qRT*-PCR, immunofluorescences, transfections assay with reporter constructs and expression vectors were carried out. We found that the inhibition of the NFκB factor reduced the E_2 action over the leptin expression (P£0,05), and the overexpression of the p65 subunit (Rel A) significantly increases the transcriptional activity of leptin promoter (P£0,05). On the other hand, BeWo-Sh2 cells expressing an shRNA against ERapha protein, show no effect to E_2 treatment nor with SP1 factor or with Rel A, which will suggest that theses factor requires ERalpha so it could exert its effects on E_2 leptin expression. Moreover we observed that Sp1 (P£0,05) and cAMP-PKA (P£0,05) pathway increased leptin promoter activity, instead we can counter this effect with the pharmacological inhibitors H89 (P£0,05) and SQ22536 (P£0,005). Finally by immunofluorescence we observed that there is a strong correlation between the ERalpha and the p65 subunit localization. These findings suggest that leptin expression is tightly regulated and improved the comprehension of the mechanisms where by E_2 regulates leptin expression and leptin function during pregnancy.

(455) **OXER1 ACTIVATION, BUT NOT PKA OR PKC ACTIVATION, INCREASES HUMAN ADRENOCORTICAL CELL MIGRATION**

Maria Isabel Neuman (1, 2), Nicolás Lemiña (1, 2), Fabiana Cornejo Maciel (1, 2)
(1) Universidad de Buenos Aires. Facultad de Medicina. Departamento de Bioquímica Humana. Buenos Aires, Argentina. (2) CONICET - Universidad de Buenos Aires. Instituto de Investigaciones biomédicas (INBIOMED) - CONICET. Buenos Aires, Argentina.

Lipoxygenase-dependent products of arachidonic acid metabolism act through a membrane receptor named OXER1. These compounds are produced in steroidogenic cells and are required for the activation of steroid production. We found that human adrenocortical H295R cells express OXER1 and that, in this cell type, it is involved in the PKA and PKC-dependent stimulation of steroidogenesis. Other authors have postulated that 5-oxo-ETE is a potent activator of human neutrophil migration and of prostate cancer cell proliferation. Both effects are mediated by the activation of its receptor. Here we examined the effect of PKA, PKC and OXER1 signal transduction pathways on the migration of H295R cells. The cells were cultured under different conditions and cell migration was evaluated measuring wound healing 24 h after scratch. Results are shown in arbitrary units as mean ± SEM. Treatment with 5-oxo-ETE (500 nM), agonist of OXER1, produced an increase in cell migration (control 14.3 ± 0.7 vs. 5-oxo-ETE 25.3 ± 2.5, $P < 0.003$). This result was also obtained using a cell line characterized by the stable overexpression of OXER1. In addition, H295R cells treated with 1 mM 8Br-cAMP or 0.1 mM angiotensin II did not change the migration rate (control 14.3 ± 0.7; 8Br-cAMP 10.2 ± 1.8; AII 17.5 ± 1.8). Therefore, the activation of PKA and PKC kinases might not be involved in the activation of the migration process. OXER1 activation might promote cell migration through its own signal transduction pathway. Future experiments should focus on signal transduction pathways triggered by OXER1 activation.

Keywords: OXER1 – PKA – PKC – cell migration – adrenocortical cells

(1185) **2-IODOHEXADECANAL: NEGATIVE MODULATION OF THYROGLOBULIN (TG) VIA PPARGAMMA RECEPTOR.**

Luciano Esteban Rossich (1), Juan Pablo Nicola (2), Lisa Thomasz (1), Leonardo Salvarredi (1), Marina Perona (1), Mario Alberto Pisarev (1), Guillermo Juan Juvenal (1)
(1) CNEA, (2) Universidad Nacional de Córdoba

Introduction: Iodine plays an important role in thyroid physiology and proliferation (Thyroid Autoregulation). The biosynthesis of iodolipids has been observed in the thyroid gland and their participation in thyroid autoregulation has been suggested. 2-iodohexadecanal (2-IHDA) was isolated as the major iodolipid formed in the thyroid and we have shown that this iodolipid can inhibit several thyroid parameters. A possible mechanism of 2-IHDA action would involve the Peroxisome Proliferative Activated Receptors (PPARs). **Objective:** To study the potential role of PPARs in the mechanism of action of 2-IHDA. **Methodology:** In silico analysis of consensus sequences for PPAR binding in the promoter region of relevant genes for thyroid physiology was performed using the PROMO 3.0 application. We decided to study the effect of PPARs on Tg gene expression. FRTL-5 cells were cultured and treated for 24 h with increasing doses of 2-IHDA. Tg mRNA levels were assessed by RT-qPCR. The transcriptional activity of the Tg gene was determined by reporter gene assays using the pTg -688 and the pTg -688 PPAR mutated construct coupled to luciferase. The binding of PPARγ to the Tg pro-

moter was performed by chromatin inmunoprecipitation (ChIP) studies. Since the Tg promoter region has only one site for PPAR gamma, assays were performed applying rosiglitazone maleate agonist, siRNAs and inhibitors (GW9662) to this isoform. **Results:** Reporter gene assays revealed that 2-IHDA promoted the transcriptional activity of PPARγ. The PPARγ agonist mimicked the repressor effect of 2-IHDA on Tg mRNA levels. GW9662 and the PPARγ siRNA reversed the effect of 2-IHDA. ChIP analysis revealed that 2-IHDA promoted an increase in PPARγ interaction with the Tg promoter. Transfection studies showed an inhibition on Tg gene expression caused by 2-IHDA while transfection with the pTg -688 PPAR mutated construct showed no effect. **Conclusion:** 2-IHDA modulates Tg gene expression by inducing PPARγ repressor activity.

(1082) **CHARACTERIZATION OF THE INITIATION TRANSLATION FACTOR eIF4G$_1$ AS A PKA SUBSTRATE IN *Saccharomyces cerevisiae***

Clara Andrea Solari, Adriana Carla Camarano, Pía Valacco, Silvia Moreno, Paula Portela
Dpto. Química Biológica FCEN-UBA/IQUIBICEN-CONICET.

PKA has a central role in the control of the metabolism, stress resistance and proliferation in *Saccharomyces cerevisiae*. In response to nutrient consumption, *S. cerevisiae* arrests cell cycle, decreases global protein synthesis and initiates translation through internal ribosome entry sites (IRES). We have recently demonstrated that PKA connects the nutritional state of the cell with translation at different levels: through interaction with translation factors, by localization in mRNA granules and affecting the protein abundance of translation initiation factor eIF4G$_1$ by a post-translational mechanism. Phosphoproteomic assays have reported that eIF4G$_1$ is a phosphoprotein. The aim of this work was to characterize eIF4G$_1$ as a PKA substrate and to identify the phosphorylation target residues. For this purpose, the full length and different fragments of recombinant proteins derived from GST-eIF4G$_1$ were expressed and purified using a pGEX system. Using these proteins, we assayed *in vitro* phosphorylation with Tpk1 and Ca as the catalytic subunit from *S. cerevisiae* and mammals respectively. The GST-eIF4G$_1$ phosphorylation was studied by western blot using an anti-P-Ser antibody and autoradiography for the incorporation of γ-^{32}P [ATP]. The phosphorylated residues were identified by nano-LC MS/MS applying an iron trap chromatography. Our results demonstrate that eIF4G$_1$ is a PKA substrate *in vitro* and identify Thr^{934} as a novel phosphorylation target residue in eIF4G$_1$. Since, Thr^{934} residue localizes on the RNA-binding domain RNA3 at the extreme C-terminus, we will focus on studying the role of this phosphorylation site over eIF4G$_1$ protein abundance and its recruitment to the 43S preinitiation complex on the mRNA.

BIOPHYSICS 3

(1504) **BIOPHYSICAL BASIS OF MULTIPLE CELLULAR TARGET RECOGNITION BY HPV E6 ONCOPROTEINS**

Irina P. Suarez, Bonhoure Anna, Chebaro Yassmine, Alexandra Cousido-Siah, Andre Mitschler, Alberto D. Podjarny, Gilles Trave
Institute of Genetics, Molecular and Cell Biology (IGBMC), CNRS, INSERM, UdS, Illkirch/Strasbourg, France

Human papillomaviruses (HPVs) are small DNA viruses that infect mucosal or cutaneous epithelia. While “low-risk” HPVs generate only benignant proliferations, the so-called “high risk” HPVs can generate malignant proliferations, which are responsible for 5% of human cancers worldwide.

All HPV types express the E6 oncoprotein, which is a critical player in carcinogenesis induced by HPV. Most E6 oncoproteins share a common molecular property: they recognize short linear motifs containing the LxxLL consensus sequence on their cellular targets. The LxxLL motif adopts a helical conformation to dock into a hydrophobic and positively charged pocket built up by the two zinc-binding domains of E6.

Through LxxLL motif recognition one particular E6 can interact with a pool of different targets. The identity of the targeted proteins varies with the E6 proteins from different papillomaviruses, which could result in different global biological effects. Integrating affinity measurements, X-ray crystallography structures and molecular dynamics data on E6:LxxLL complexes from divergent papillomaviruses we aim to unravel the structural determinants of LxxLL motif recognition that distinguish high-risk/low-risk and cutaneous/epithelial HPV types. Here we present what we learned from two novel high resolution E6 structures from HPV18 and 49 combined with affinity determinations for their complete set of potential cellular targets.

Keywords: HPV, E6, X-ray crystallography

(1498) **EVALUATION OF THE CONFORMATIONAL CHARACTERISTICS OF THE HUMAN LYR PROTEIN ISD11.**

Georgina Herrera (1), Manuel Toribio (1), Karen Cruz (1), Nadia Chiaramoni (2), Javier Santos (1)
(1) IQUIFIB-Universidad de Buenos Aires. (2) Universidad de Quilmes.

Abstract: The leucine/tyrosine/arginine family (LYRMs) is a group of proteins with an adaptor like function essential for cell metabolism. One of them is ISD11 which interacts with the cysteine desulfurase NFS1, a key-component of the Fe-S cluster biogenesis machinery inside mitochondria. This interaction provides stability to NFS1 and it has a central role in the ISCU/HSPA9/HSC20 protein complex that transfers Fe-S clusters from ISCU to target proteins. Recently, it was shown that ISD11 also interacts with the mitochondrial acyl carrier protein (ACP) by electrostatic forces and exhibits alpha helical structure in which an acyl chain (linked via phosphopantetheine cofactor to ACP) is interacting with core residues of ISD11. In this context, our main objective is to understand how ISD11 acquires its structure and stability. Previous results showed that purified (isolated) ISD11 has a high tendency to aggregate. Herein, we present that the addition of the detergent n-Dodecyl β-D-maltoside (DDM) and high concentration of NaCl allows us to obtain soluble protein. By far-UV CD analysis, we observe that the protein is completed folded. We conjecture that the detergent may mimic the acyl group and its structural role, whereas NaCl diminishes the electrostatic repulsion on the surface of ISD11 when protein partners are absent. This result opens the possibility to study the role of the acyl chain on ISD11 stability and the role of ISD11 in the interactions with NFS1 and ACP among others.

To further evaluate ISD11 structure, we obtained the helical regions of ISD11 as three peptides and we evaluated the secondary structure and activity of them in the context of the NFS1-ISD11 complex. By Far-UV CD spectra we have confirmed they present an alpha-helix structure and we have determined that the N-terminal region interacts with negative charged membranes. This suggests that ISD11 may be important for the anchoring the NFS1 protein complex to the mitochondrial membrane.

Keywords: Conformational characterization, peptide-lipid interaction, desulfurase activity.

(1784) **PANNEXIN 1 EXPRESSION IN *XENOPUS LAEVIS* OOCYTES**

Luciano Galizia (1), Juan Guarracino (1), Adriana Losavio (1), Karina Alleva (2), Pablo Schwarzbaum (2)
(1) IDIM-UBA/CONICET. (2) IQUIFIB-UBA/CONICET.

Six subunits of Pannexin 1 (Panx1) form a plasma membrane channel termed ‘pannexon’. The pannexon can function as a small-conductance chloride selective channel, activated by an increase of membrane potential (Vm). Alternatively, a non selective high- conductance mode was reported, where the channel can be activated by increases in extracellular potassium concentration (K^+)e and permeate molecules less than 1.5 kD. In addition to K^+e and Vm, hypotonicity was suggested –but not thoroughly proven- to activate Panx1 activity.

In this context we used Xenopus oocytes as an expression system to express Panx1, and characterize the modulation of Panx1 currents by K^+e and hypotonicity.

Expression of Panx1 was assessed by two-electrode voltage

clamp technique. We employed a voltage step protocol to evaluate the small conductance mode or a continuous pulse protocol to observe the high conductance mode. By applying a voltage step protocol in Panx1 injected oocytes we observed voltage sensitive outward currents that were absent in water injected oocytes (I_{panx1} at 60 mV = 0.60 ± 0.12 μA, n=10 vs I_{water} at 60 mV 0.12 ± 0.01μA, n=7, p<0.05), while addition of CBX (a Panx1 inhibitor) suppressed these currents. Assessment of Panx1 by $(K^+)e$ stimulation was performed in a continuous pulse protocol. A 5-fold increase of currents was evidenced in Panx1 injected oocytes, suggesting the presence of high conductance mode. On the other hand, hypotonic medium (50 mOSM, 1.5 min), as compared to isotonic control, did not alter the magnitude of currents (I_{iso} 60 mV = 0.31 ± 0.12 μA vs I_{hypo} 0.33 ± 0.12 μA, n=5, NS). Results suggest that $(K^+)e$, but not hypotonicity, was able to activate Panx1 into the high conductance mode of pannexon. This data could be relevant in the understanding of the Pannexin 1 role during cell volume changes.

(1376) **PROCYANIDIN DIMERS INTERACTION WITH PORCINE PANCREATIC LIPASE**

Juana Inés Mosele (1), Mariana Larrauri (2), Valeria Nepote (3), Cesar Guillermo Fraga (1), Mónica Galleano (1)

(1) Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Departamento de Química Analítica y Fisicoquímica, Cátedra de Fisicoquímica; CONICET - Universidad de Buenos Aires, Instituto de Bioquímica y Medicina Molecular (IBIMOL). (2) Universidad Nacional de Córdoba, Facultad de Ciencias Agropecuarias, (IMBIV CONICET)). (3) Universidad Nacional de Córdoba, Facultad de Ciencias Exactas, Físicas y Naturales, (IMBIV CONICET).

The aim of this work was to study the effect of procyanidin dimers enriched fractions from peanuts skins on porcine pancreatic lipase (PPL) activity and characterize this interaction. Extracts were obtained from skin peanuts (type Runner from Argentina, crop 2012) subjected to blanching (90ºC, 10 min), extracted with ethanol-water (70:30 v/v) following by an ethyl acetate extraction to obtain three fractions: purple (PF), brown (BF) and yellow (YF). Interaction with PPL was studied in terms of enzymatic activity and quenching of fluorescence. Enzymatic activity was tested by monitoring the cleavage of 1,2-O-dilauryl-rac-glycerol-3-glutaric acid (6-methyresorufin) ester to produce methylresorufin previous incubation of PPL with 0–2.5 mg/ml of fractions. Orlistat and epigallocatechin gallate were used as positive controls. PPL inhibition order was YF ≈ BF > PF with IC_{50} of 1.0±0.1 mg/ml, 1.2±0.1 mg/ml and >2 mg/ml, respectively. Quenching of fluorescence (λ_{exc}= 295 nm) showed a decreased in Intensity without changes in the maximum peak position, suggesting that the microenvironment of the tryptophan residues is not changed. Data obtained from double logarithmic Stern-Volmer equation was applied to calculate binding constants of YF and BF at different temperatures obtaining the thermodynamic parameters. The binding process was spontaneous (ΔG at 298K = -22.0 and -20.8 kJ/mol for YF and BF, respectively), endothermic (ΔH=13.7 and 39.5 kJ/mol for YF and BF, respectively) and with an increase of entropy (ΔS=121 and 203 J/K mol for YF and BF, respectively).

Based on the fractions composition, analyzed by HPLC-ESI-MS/MS, the inhibitory effect was associated to the presence of procyanidin dimers type A, and in a less extent to procyanidin dimers type B. Experiments with purified procyanidin dimers A1, B1 and B2 confirm the results.

These results suggest that compounds isolated from peanut skin can be a useful food ingredient with the potentiality of decrease fat absorption in humans.

(1379) **SPECIFICITY AND REACTIVITY OF MTB PROTEIN KINASES PKNB AND PKNG**

Marisol Natalia Cabrera, Elias Daniel Lopez

Tuberculosis is one of the most important infectious diseases in the world, causing the death of about 2 million people per year, mainly in developing countries. The Pkns are the central protein kinase family of the bacillus, which is composed of 11 proteins, two particularly interesting: pknB and pknG. The cellular processes in which pknG and pknB participate are diverse. However, the axis of this work will be the study of the phosphorylation of garA, a regulator of the tricarboxylic acid cycle. T21 and T22 residues of the garA N-terminus are susceptible to phosphorylation, an event that regulates the activity of the protein. When garA is phosphorylated, phosphorylated residues interact with residues of FHA domain, preventing interaction with other proteins. PknG phosphorylates garA at threonine 21, adjacent to the residue phosphorylated by pknB (T22), and these two phosphorylation events are mutually exclusive. However, until now the reason for the specificity and the functional relevance remains unclear. In the present work, we use Molecular modeling, molecular dynamics simulations, and kinase activity assays to explain the differences in the selectivity on garA phosphorylation. We finally found that amino acid differences at the garA n-terminal are responsible for specificity. We concluded that there are two hydrophobic residues which anchor garA in the pocket of the active site of pknG and one polar residue that anchors in the pocket of pknB.

(407) **STRUCTURAL CHARACTERIZATION OF *Arabidopsis thaliana* GRF3-GIF1 INTERACTION**

Marco César Miotto, Fernando Damián Muzzopappa, Ana Paula Perrone, Javier Fernando Palatnik, Rodolfo Maximiliano Rasia

Institute of Molecular and Cellular Biology of Rosario, Ocampo y Esmeralda, Rosario, Argentina

Plant development is a process that is finely regulated by the action of various molecular mechanisms. One of these mechanisms comprises the activation or repression of the expression of certain genes, through the action of specific proteins. The Growth-Regulating Factors (GRF) – GRF-Interacting Factors (GIF) system is formed by two families of activators and transcriptional coactivators conserved in terrestrial plants. A range of studies have demonstrated the function of the combined action of these proteins on plant development, but there is no biophysical evidence of such protein-protein interaction so far.

Here we present the first structural study of *Arabidopsis thaliana* GRF3 and GIF1. The proteins show a high degree of intrinsic disorder throughout the sequence. To perform a detailed evaluation of their structural features, we designed protein constructs with the regions genetically mapped as essential for the interaction between GRF3 and GIF1, the QLQ and SNH domains, respectively. Using biophysical techniques such as Circular Dichroism and Nuclear Magnetic Resonance, we gathered information on the degree of disorder and the residual structure in these domains. Further information at a residue-specific level allowed us to begin the structural characterization of both the individual GRF3 and GIF1 and the GRF3-GIF1 complex.

Keywords: GRF, GIF, protein-protein interaction, CD, NMR

(45) **STRUCTURE AND FUNCTION STUDY OF PEPTIDES DERIVED FROM *E. Coli* ALPHA HEMOLYSIN FOR THE CONSTRUCTION OF AN IMMUNOTOXIN**

Lucia Cane (1), Fanny Guzmán (2), Sabina Maté (1), Vanesa Herlax (1)

(1) Instituto de Investigaciones Bioquímicas de La Plata (INIBIOLP), CCT- La Plata, CONICET. Facultad de Ciencias Médicas. Universidad Nacional de La Plata. (2) Núcleo Biotecnológico de Curauma, Pontificia Universidad Católica de Valparaíso, Chile

Abstract: Escherichia coli alpha hemolysin (HlyA) is a pore-forming protein which belongs to the family of 'Repeat in toxins'(RTX). On the basis of experimental data and structural predictions, four

peptides derived from HlyA were synthesized: PEP 1: transmembrane domain described as hemolytically active; PEP 2: also a transmembrane domain which sequence corresponds to a cholesterol binding domain (CARC); PEP3: similar to PEP2 but with residue Y^{347} substituted by A and PEP4: similar to PEP2 but with a CRAC sequence ("cholesterol recognition/interaction amino acid consensus domain"). The aims of this work were to study the participation of CRAC and CARC in the stabilization of HlyA monomers in membranes by their interaction with cholesterol, to evaluate the role of Y^{347} in the interaction with membrane, and finally to find a cytotoxic peptide for the construction of an immunotoxin. Peptides were synthesized by the solid phase peptide synthesis method (Fmoc strategy), purified by HPLC (C-18 column), the molecular mass was determined by mass spectrometry and peptide structure by circular dichroism. The hemolytic activity of peptides was measured using human erythrocytes, and cytotoxicity using the MTT reduction method on the breast cancer cell line MCF-7. Results describe PEP2 as hemolytic and cytotoxic, which is promising and encourage us to use it in the design of immunotoxins. PEP3 was found not to be cytotoxic suggesting residue Y^{347} is fundamental for the interaction of HlyA with lipidic membranes. PEP4 was found not to be hemolytic nor cytotoxic, which implicates the CRAC sequence added was unfavorable for peptide activity.

In conclusion, we synthesized, and study the structure and activity, of four peptides derived from HlyA of *E. coli*. Also, we found a peptide that it is both cytotoxic and hemolytically active, which leads our group to the design and construction of an immunotoxin comprising PEP2 and an antibody that specially recognizes tumoral cells.

Keywords: immunotoxins, cancer, *E. Coli.*

(79) **THE INTERFACIAL PROPERTIES OF THE HIV-1 GAG MATRIX DOMAIN ARE MODULATED BY PROTEIN MYRISTOYLATION AND NUCLEIC ACID BINDING**

Luis Benito Pérez Socas, Ernesto Ambroggio
Centro de Investigaciones en Química Biológica de Córdoba

Abstract: The specific traffic and assembly of the HIV-1 GAG protein at the plasma membrane (PM) is tightly regulated by the myristoylation of its matrix domain (GAG_{MA}) and its binding to RNA. When GAG reaches the PM a perfect protein monolayer is formed. Understanding how this layer is constituted and stabilized is relevant to develop new strategies aiming to interrupt the gemmation of new viral particles at the membrane. For this reason, we studied the stability, thermodynamics and the topography if this first protein layer from Langmuir monolayers composed of the myristoylated or unmyristoylated versions of GAG_{MA} in the presence or the absence of a single strand DNA (ssDNASel25), an analog of the Sel25 RNA sequence, that tightly binds GAG_{MA}. We also used a similar approach to study monolayers of GAG_{MA} -derived peptides (first 21 resides of GAG_{MA}) in their myristoylated and unmyristoylated forms. Our results show that the protein/peptide films are destabilized by the presence of ssDNASel25, inducing solubilization of the film components into the bulk phase. In addition, the oligonucleotide affects the protein-protein or peptide-peptide lateral interactions provoking interfacial topography changes of the monolayers, visualized by Brewster angle microscopy. Additionally, we show how the myristoyl group has major effects on the lateral stability and the elasticity of the monolayers. Altogether, here we propose a general model for GAG_{MA} interfacial association, considering the effect of myristoylation and the interaction with oligonucleotides. The model proposes a new role of GAG_{MA} based on the lateral stabilization of protein monolayers.

Keywords: Human immunodeficiency virus, HIV-1 GAG matrix domain, Oligonucleotide interaction, Brewster-angle microscopy, Langmuir monolayers.

(881) **THERMAL STABILITY AND INACTIVATION OF THE CATALYTIC DOMAIN FROM THE COPPER ATPASA OF THE THERMOPHILIC *ARCHAEOGLOBUS FULGIDUS***

Santiago Agustín Martinez Gache
IQUIFIB

Abstract: The copper (I) ATPase from *Archaeoglobus fulgidus* (*Af* CopA) is an integral membrane protein composed of the following cytoplasmic domains, catalytic (ATP-PN), actuator and two metal binding domains. The independently folding catalytic domain is responsible for the ATPase activity at 70 ^{0}C. We evaluate the thermal inactivation of ATP-PN as a function of the time at several temperatures, through activity, intrinsic fluorescence and circular dichroism measurements. In all the temperatures tested, high amounts of residual secondary structure after the decrease or even full loss of the ATPase activity where found. Comparison between *Af* CopA and his isolated ATP-PN shows more resistance of the former to thermal inactivation than *Af* CopA. Thermal stability was evaluated through bioinformatics and structural analysis of ATP-PN and his orthologs in hyperthemophilic, thermophilic, mesophilic and pscychrophilic microorganisms. Our results show similar hydrophobic, aromatic, glycine and proline amino acid composition among the different microorganisms evaluated. Increased number of charge residue and decrease number of polar residue was observed from psycrophilic to hyperthermophilic. Structural analysis reveals different distributions and numbers of electrostatics and hydrogen bond interactions between the microorganisms evaluated.

Keywords: thermal stability, inactivation, functional, structural, bioinformatics.

(1801) **HIS-TAG β-GALACTOSIDASE IN HETEROGENOUS SYSTEM**

Sandra Soledad Flores Mamani, Milagro Mottola, Maria Angelica Perillo, Julieta Maria Sanchez
Instituto de Investigaciones Biológicas y Tecnológicas (IIByT), CONICET, Cátedra de Química Biológica, Departamento de Química, Facultad de Ciencias Exactas, Físicas y Naturales, FCEFyN, Universidad Nacional de Córdoba

The *Escherichia coli* β-galactosidase (β-Gal) is a widely used enzyme for basic and applied research. Usually, the enzyme activity is measured in heterogeneous media. In our laboratory, we demonstrated that β-Gal can interact with lipid/water interfaces. In this condition we observed an enhanced catalytic activity, an increase in thermostability and the prevention of β-Gal proteolysis. Currently we are producing a recombinant $\beta\text{-Gal}_{His}$ (6 histidine residues at the carboxy terminus). These additional histidines (His-tag) decreases significantly (circa 50%) the catalytic activity of the protein. On the other hand, in the presence of lipid interfaces an important superactivation (up to 100%) is also observed. Since at the working pH 6.8 an important population of histidine residues are dissociated and conferred additional positive charges to the enzyme, we evaluated the ability of negatively charged interfaces to modulate $\beta\text{-Gal}_{His}$ activity. Interestingly the superactivation exerted by DOPC:DOPG (80:20, molar ratio) MLVs is even greater than that induced by zwitterionic bilayers of pure DOPC. The molecular organization of those lipid mixtures at the air-water interface served as membrane models and were studied through surface pressure–mean molecular area compression isotherms. Monolayers were composed of pure DOPC, pure DOPG or DOPC:DOPG mixtures at different molar ratios (80:20, 60:40, 40:60 and 20:80). Mixtures showed a non-ideal behavior with positive deviation from ideality (repulsive interaction between the components). Our results suggest that, beyond the attractive electrostactic interactions between the positively charged His tag and the negatively charged surface, the higher sensitivity to the negative interface is being favored by the reduction of the surface free energy associated to the $\beta\text{-Gal}_{His}$–membrane binding. This contributes to an increased surface density of $\beta\text{-Gal}_{His}$ at the membrane which translates into an increased specific activity.

Keywors: β-galactosidase, interfaces lipidic, monolayer

STRUCTURAL AND FUNCTIONAL BIOCHEMISTRY 3

(76) **STUDIES ON THE LIPID A STRUCTURE OF *BRUCELLA SUIS* AND *BRUCELLA ABORTUS* LIPOPOLYSACCHARIDE**

Adriana Cristina Casabuono (1), Cecilia Czibener (2), Mariela G Del Giudice (2), Ezequiel Valguarnera (2), Juan E. Ugalde (2), Alicia S. Couto (1)

TECH, CONICET, Universidad Nacional de San Martín, Buenos Aires, Argentina

Abstract: Brucellae are Gram-negative bacteria that cause brucellosis, one of the most worldwide distributed zoonosis, transmitted to humans by contact with either infected animals or their products. The lipopolysaccharide (LPS) exposed on the cell surface is considered a major virulence factor of *Brucella,* and it induces a strong antibody response during infection when whole cell vaccines are used. LPSs present three regions with different chemical and biological properties: the lipid A, the core oligosaccharide and the O-antigen. In the last years although some studies go deeper into the structures of the core and the O-antigen of these LPS, no analysis of the lipid A has been performed. In this context, we have analyzed in depth the structure of the lipid A isolated from *Brucella suis* and *Brucella abortus* LPSs. The lipid A moieties were released by acid hydrolysis from both LPS and analyzed by MALDI-TOF mass spectrometry in the positive and negative ion modes, using different matrices. Interestingly, a new feature was detected: the presence of a pyrophosphorylethanolamine residue (PPEtN) substituting the backbone. LID-MS/MS analysis of some of the detected ions allowed to assure a Lipid A structure composed by a diGlcN3N disaccharide, mainly hexa-acylated and penta-acylated, bearing one phosphate and one PPEtN residue. As one mechanism of antimicrobial peptide resistance is to modify the cell surface with positively charged moieties, the finding that *B. abortus* and *B. suis* contain one PPEtN on their lipid A moieties may open new possibilities for exploring into the not fully elucidated set of mechanisms involved in Brucellae virulence that include the ability to escape prompt detection by innate immunity during the initial stages of infection.

Keywords: Brucella, lipopolysaccharide, Lipid A, MALDI-TOF MS.

(502) **INHIBITION BY PRODUCT. A DIFFERENTIAL MODE OF REGULATION BETWEEN FERREDOXIN-NADP⁺ REDUCTASES**

Paula Monchietti, Eduardo A. Ceccarelli, Daniela L. Catalano-Dupuy
Instituto de Biología Molecular y Celular de Rosario

Ferredoxin-NADP⁺ reductases (FNR) are flavoenzymes involved in biologically relevant processes. FNR catalyzes the reversible electron transfer between NADP(H) and ferredoxin or flavodoxin. The reaction involves a hydride exchange with the pyridine nucleotide and then an electron transfer to or from the other substrate. We have previously identified that *Escherichia coli* FNR is purified with the substrate/product NADP⁺ tightly bound. The nucleotide binding produces an inhibition of the enzyme activity which is lost when NADP⁺ is released. Our findings suggest that this inhibition may have a regulatory function on this bacterial FNR and would implicate a different catalytic mechanism than the one reported for the plastidic enzymes. *E. coli* FNR belongs to one of the three plant-type FNR groups in which these enzymes can be classified. These groups have well-identified structural differences. One of the most relevant is located in the carboxyl terminus of FNR, where NADP⁺ binding and catalysis occur. We have comparatively studied the catalytic properties of FNR from different pathogenic bacteria: *E. coli*, *Pectobacterium carotovorum*, *Brucella abortus* and *Leptospira interrogans*, in order to determine if the phenomenon observed in *E. coli* reductase is a unique process of bacterial FNR. We found that all the aforementioned reductases, except *L. interrogans* FNR, contain NADP⁺ bound. Moreover, kinetic analyses of these enzymes allowed establishing a direct correlation between the ability of high-affinity binding of NADP⁺ and a decrease of their catalytic efficiences. It is important to note that *L. interrogans* possesses a plastidic FNR. We propose that this regulation would be an important aspect of the functionality of the enzymes and, therefore, in the regulation of redox homeostasis in bacteria. From these results, we propose using this high-affinity binding as a differential target for the inactivation of metabolic pathways in which FNR participate in pathogenic bacteria.

Keywords: Ferredoxin-NADP⁺ reductase, inhibition, electron transfer, catalytic mechanism

(505) **MOLECULAR AND BIOCHEMICAL CHARACTERIZATION OF PYRUVATE DECARBOXYLASE IN THE FRUCTOPHILIC NON-*SACCHAROMYCES* YEAST *STARMERELLA BACILLARIS***

Francisco Conti, María Laura Raymond Eder, Alberto Luis Rosa
IRNASUS-CONICET-UCC

S. bacillaris is a fructophilic non-*Saccharomyces* yeast ubiquitously present in grapevine ecosystems. *S. bacillaris* is a promising species to be used in mixed alcoholic fermentations with *S. cerevisiae* to reduce alcohol content of wines. We have recently proposed that pyruvate decarboxylase (PDC), a key enzyme at the branch-point of the respiratory versus fermentative pathways, may show genetic and phenotypic diversity among grapevine yeasts evolving in different *Vitis* ecosystems. In this work we present our preliminary characterization of the structural gene encoding PDC and the PDC enzyme from *S. bacillaris* strains isolated from *V. vinifera* and *V. labrusca* fermenting grape musts. PDC activities were determined on total cell protein extracts, coupled with alcohol dehydrogenase and measuring the oxidation rate of NADH at 340 nm. Kinetic parameters (i.e., substrate activation, $K_{0,5}$, V_{max} and K_{cat}) of *S. bacillaris* PDC were established on two selected indigenous strains. PDC activity in *S. bacillaris* and *S. cerevisiae* strains, isolated from *V. vinifera* and *V. labrusca* ecosystems, was determined in cells growing in media supplemented with glucose or fructose as carbon sources. Similar PDC activities were observed in *S. bacillaris* cells growing in both media. *S. cerevisiae* cells, on the other hand, showed a much higher PDC activity when cells were grown in media containing glucose versus fructose. These results could highlight the underlying metabolic control of PDC activities in a fructophilic (*S. bacillaris*) versus a glucophilic (*S. cerevisiae*) yeast species. This preliminary study contributes to the recognition of the biodiversity of PDC in wine yeast species, evolutionary adapted to alternative *Vitis* ecosystems.

Keywords: Vitis, yeast, *S. bacillaris*, *S. cerevisiae*, pyruvate decarboxylase

(784) **BIOCHEMICAL AND PHYSIOLOGICAL CHARACTERIZATION OF A 3-METHYLCROTONYL-COA CARBOXYLASE COMPLEX FROM *Xanthomonas***

Lautaro Diacovich, Betiana Garavaglia (1), Mauro Tomassetti (1), Cecilia Vranych (1), Natalia Gottig (1), Jorgelina Ottado (1), Hugo Gramajo (1)
(1) IBR

The phytopatogen *Xanthomonas axonopodis pv. citri* (Xcc) produce canker, pathology that affects citric. Xcc, as an obliged plant parasite, is unable to survive out of its host for long periods of time. Nevertheless, during the epiphytic survival state, over the leaf, many metabolic and nutritional aspects remain unknown. Branched-chain aminoacids catabolism prevents their over-accumulation, facilitates branched-chain fatty acids biosynthesis and provides energy for the cell. The enzymatic complex 3-methyl-crotonyl-CoA carboxylase (MCC) is essential for leucine degradation pathway. MCC carboxylates 3-methyl-crotonyl, as a substrate, to finally generate acetyl-CoA and acetoacetate, which are latter incorporated into different metabolic pathways. MCC complexes belong to the biotin-dependent acyl-CoA carboxylases (ACCases) group. The objective of this work was characterized a MCC complex from Xcc. We identified by bioinformatics two genes that encode two subunits of an ACCase complex in *Xanthomonas*, and others gram negative bacterial pathogens. We purified the two ACCases subunits, AccC and AccD, by affinity columns and reconstituted the enzymatic activity *in vitro* using different acyl-CoAs as substrate. For this we used two methods, including fixation of radiolabeled bicarbonate and a coupled assay. We determined the kinetic parameters and confirmed that these proteins conform a MCC complex. Furthermore, we had shown, by using a mutant analysis, that this MCC complex is relevant for the survival of Xcc *in planta*.

(878) **LIPOATE BIOSYNTHESIS IS ESSENTIAL FOR *CAENORHABDITIS ELEGANS* DEVELOPMENT**

Antonela Lavatelli, Diego de Mendoza, María Cecilia Mansilla
Instituto de Biología Molecular y Celular de Rosario

Lipoic acid is a universally distributed sulfur containing cofactor. It is derived from octanoic acid and it is essential for the functioning of multienzymatic complexes involved in oxidative and one-carbon metabolism. It is also a potent antioxidant. The ways in which prokaryotes proteins become post-translationally modificated with LA are very well understood. On the contrary, eukaryotes lipoylation pathways are not clearly characterized, even in simple organisms such as yeast. There are several reports of human patients defective in protein lipoylation who died in early life or survived but with severe neurological disorders. Treatment for those patients was just to alleviate symptoms. Our goal is to elucidate how proteins become lipoylated in the nematode *Caenorhabditis elegans* in order to understand the process in humans and develop new therapies. By complementation assays we have already demonstrated that *C. elegans* M01F1.3 protein is the worm lipoate synthase. We also reported that its depletion by interference RNA (RNAi) caused a larval arrest phenotype in the second generation of N2 worms. Here we show that this experiment carried out in a RNAi hypersensitive strain also generates a larval arrest phenotype, but in the first generation ($p<0.01$). Notably, the addition of exogenous lipoate was unsuccessful to restore the normal life cycle. Worms subjected to RNAi treatment that were incubated in presence of Fe (II) exhibited a lower resistance to oxidative stress compared to control animals ($p<0.05$). RNAi experiments were also performed with strains that allow tissue-specific knockdown, and we found that M01F1.3 expression is necessary in neurons for the correct development of worms. These results support that M01F1.3 is essential for the correct development of the worms and suggest that its expression is crucial in neurons.

Keywords: lipoic acid, nematode, RNA interference

(909) **STUDY OF THE SYNTHESIS AND DEGRADATION OF THE CARBON RESERVE POLYMER IN *EUGLENA GRACILIS***

Robertino José Muchut, Rodrigo Daniel Calloni, Diego Gustavo Arias, Alberto Alvaro Iglesias, Sergio Adrian Guerrero
Lab. Enzimología Molecular - IAL (CONICET-UNL)

Euglena gracilis is a fresh water protist able to grow photosynthetically or heterotrophically using a diverse array of organic compounds as the sole source of carbon and energy for growth. *E. gracilis* is a suitable source for the generation of several compounds used for the production of cosmeceuticals, nutraceuticals, food, paramylon and wax esters. When grown aerobically it produces an insoluble β1,3glucan as storage polymer. Synthesis of carbon reserve polymer (paramylon) occurs via UDP-glucose, a key metabolite of the carbohydrate pathways present in most organisms, generated in a reaction catalyzed by UDPglucose pyrophosphorylase (EC 2.7.7.9; UDP-GlcPPase).The enzyme from *E. gracilis* was expressed in *Escherichia coli* cells. The purified enzyme was kinetically characterized, catalyzing UDP-glucose synthesis with a V_{max} value of 3350 U/mg, and affinity for substrates of 0.24 mM and 0.17 mM for glucose1P and UTP respectively. We have also performed, for the first time, confocal microscopy assays to visualize the intracellular location of UDP-GlcPPase.

On the other hand, degradation of paramylon is catalyzed by β-1,3-glucanases. We found several transcripts corresponding to endo-β-1,3-glucanase (EC 3.2.1.39) belonging to different glycoside hydrolases (GH) families. Activity β-1,3-glucanase were measured achieving 0.05 U/mg from soluble fractions of crude extract and 0.03 U/mg from membrane fractions solubilized with detergent. In order to deepen the knowledge in the degradation of the paramylon, we performed the novo synthesis and molecular cloning of two genes coding for two endo-β-1,3-glucanase, one from GH 17 family and the other one from GH 64 family. These genes were used for recombinant expression in *Escherichia coli* cells.These results obtained allow us to improve our understanding about carbon reserve metabolism in *Euglena gracilis* for biotechnological purpose.

Granted by ANPCyT (PICT´15 1149 y PICT´15 1767).

Keywords: Euglena gracilis, paramylon, UDP-glucose pyrophosphorylase, endo-β-1,3-glucanase.

(914) **ENZYMATIC CHARACTERIZATION OF A BETA-D-GLUCOSIDASE FROM *THERMOANAEROBACTER BROKII.***

Alem Storani, Alberto Alvaro Iglesias, Sergio Adrian Guerrero
IAL-CONICET-UNL

Abstract: Beta-glucosidases (EC 3.2.1.21), catalyze the hydrolysis of glycosidic bonds to terminal non-reducing residues in beta-D-glucosides and oligosaccharides, with release of glucose. These enzymes are powerful tools for degradation of lignocellulosic residues in biofuels production, as well as in a number of other biotechnological applications. The gene coding for the β-D-glucosidase (*cglT*) of *T.brokii* was obtained by *de novo* synthesis, after which it was cloned into a pET22b(+) expression vector. The gene was heterologously expressed in Escherichia coli BL21 (DE3) cells and the recombinant enzyme fused to a His-tag (C-term) was chromatographically purified by a His Trap™ IMAC HP column. The purification yield was of 14.7 mg of electrophoretically pure recombinant protein per litre of culture. The pure enzyme was biochemically characterized. Its enzymatic activity was optimal at pH 6.0 and between 65-70°C. The enzyme showed thermal stability, retaining 73% of the activity after incubation at 70 °C during 1 h. The enzyme kinetics was analyzed by using 4nitrophenyl-β-D-glucopyranoside and cellobiose as substrates, obtaining the respective kinetic parameters of V_{max} 63.9 U/mg and 177 U/mg; $S_{0.5}$ 0.10 mM and 1.12 mM. These properties make this enzyme an attractive candidate for being used as a component in a pilot process of enzymatic degradation of lignocellulosic residues to obtain ethanol or hydrogen based bioenergy. Molecular modeling of this protein is underway to determine structure to function relationships useful for the design of specific modification to obtain an enzyme optimized for application in biorefinery processes.

Keywords: Beta-glucosidase, hydrolysis, biofuels.

(933) **ON THE METABOLISM OF GLYCERALDEHYDE-3-PHOSPHATE IN *NITROSOMONAS EUROPAEA***

Maria Cecilia Corregido, Claudia Vanesa Piattoni, Matías Damián Asencion Diez, Alberto Álvaro Iglesias
Instituto de Agrobiotecnología del Litoral (CONICET-UNL)

Nitrosomonas europaea is a chemolithoautotroph that obtains energy through the oxidation of ammonia to nitrite in the presence of oxygen and fixes CO_2 through the Benson-Calvin cycle (BCc). In the BCc, ATP and NADPH are utilized to reduce 3P-glycerate (3PGA) to glyceraldehyde-3-phosphate (Ga3P); this being opposite to what occurs in glycolysis, where Ga3P is oxidized to 3PGA to produce energetic or reductive power. In this metabolic enclave, Ga3P dehydrogenases (Ga3PDHases) play a critical role. In plants, four Ga3PDHases were identified: GAPA/B (EC 1.2.1.13, chloroplastidic), GAPC (EC 1.2.1.12; both, plastidic or cytosolic) and GAPN (EC 1.2.1.9, cytosolic). Based on sequence homology we identified in the *N. europaea* genome the genes *Neu0327* and *Neu2000* as coding for putative GAPC and GAPN, respectively. To further explore the probable role of these two genes in triose-P metabolism in the bacterium we cloned and expressed them in *E. coli*; then we purified the proteins and characterized them kinetically. *Neu0327* expression produced a typical GAPC like Ga3PDHase, catalyzing the reversible oxidation of Ga3P to 1,3bisP-glycerate, using specifically NAD^+ as cofactor and with ~6-fold higher activity in the glycolytic direction of reaction. On the other hand, the protein product of *Neu2000* irreversibly oxidized Ga3P to 3P-glycerate using NAD^+ or (preferentially, with 33-fold higher catalytic efficiency) $NADP^+$, thus resembling a GAPN enzyme. However, the activity of the latter with Ga3P was negligible when compared to that assayed using succinate semialdehyde (SSA) as a substrate; which suggests that *Neu2000* codes for an SSA dehydrogenase (EC 1.2.1.16, SSADHase). Altogether, our results support a scenario for *N. europaea* where only one NAD^+/NADH dependent Ga3PDHase is involved in the metabolism of triose-P (via the BCc as well glycolysis/gluconeogenesis); while the protein product of *Neu2000* would preferentially act as an SSADHase with low potential to have a GAPN function.

Key words: glyceraldehyde-3-phosphate, succinate semialdehyde, *Nitrosomonas europaea*, Benson Calvin cycle, glycolysis.

(1465) **RE-ROUTING GLUCOSAMINE-1P FATE TOWARDS ALTERNATIVE ENZYMATIC STEPS IN *Rhodococcus jostii***

Antonela E Cereijo (1), Matías Damián Asencion Diez (1), Héctor M Álvarez (2), Alberto A Iglesias (1)
(1) Instituto de Agrobiotecnología del Litoral (CONICET-UNL). (2) Instituto de Biociencias de la Patagonia (CONICET-UNPSJB).

The amino sugar glucosamine (GlcN), 2-amino-2-deoxy-D-glucose, is an essential component of glycosaminoglycans and glycoproteins. Together with *N*-acetylglucosamine (GlcNAc) are among the most prevalent sugars in the biosphere and a major component in cell envelopes of fungi and bacteria. Consistent with the ubiquity of these sugars, pathways for their metabolism (including catabolic and anabolic processes) are conserved in bacteria. GlcN is biosynthesized from fructose6-P and is further acetylated to GlcNAc. The balance between GlcN and GlcNAc is essential for bacterial growth and involves GlcN-1P as a mere intermediary. Curiously, we recently discovered that GlcN-1P is efficiently used as a substrate by enzymes related to glycogen metabolism in *Rhodococcus jostii*. ADP-glucose pyrophosphorylase (ADP-GlcPPase, EC 2.7.7.27) activates Glc-1P to ADP-Glc which acts as glucosyl donor for glycogen synthase (GlgSase, EC 2.4.1.21). GlcN-1P is a substrate of ADP-GlcPPase (mainly after activation), which represents a unique feature among this enzyme from different organisms. Also, the actinobacterial GlgSase uses ADP-Glc and Glc-1P to synthesize maltose-1P as a key metabolite in these organisms. We found that a *R. jostii* GlgSase accepts GlcN1P (but not other hexose-1P) to the same extent that Glc-1P. The fact that the two enzymes catalyzing consecutive metabolic steps in the classical GlgAC pathway are able to efficiently utilize GlcN-1P suggest a role for the amino sugar different than the routing towards GlcNAc synthesis in *R.jostii*. Even more, we found that one of the annotated UDP-GlcPPases (EC 2.7.7.9) reacts 10-fold faster with GlcN-1P than Glc-1P supports the above assertion. Results presented in this work revisit GlcN metabolism in this biotechnological relevant organism. In addition, they are an important source to study the evolution of carbohydrate related enzymes and, most importantly, a source for in vitro synthesis of new compounds.

The continuous advance of metabolic syndrome and its associated pathologies (type 2 diabetes and cardiovascular disease) brought adipose tissue (AT) research back to the spotlight. In response to caloric excess, adipose tissue remodeling leads to chronic inflammation and persistent stress. In turn, these phenomena result in adipocyte hypertrophy, increased angiogenesis, immune cell infiltration, and extracellular matrix overproduction. The mechanisms and clinically relevant pathways underlying systemic chronic inflammation associated with obesity are not completely understood, Galectin-12 (Gal-12) is a tandem-repeat member of the galectin family, preferentially expressed in lipid droplets of adipocytes, with known ability to suppress lipolysis. To further understand its biological significance, we have cloned and expressed recombinant murine Gal-12 (mGal-12) in *Escherichia coli*, biochemically characterized its lectin activity and identified with preferential affinity towards Lewis X structures. Here we demonstrated the pro-angiogenic role of this lectin in transwell migration assays using human endothelial cells (HUVEC), an effect which was prevented by competition with specific saccharide ligands. Expression of m-Gal12 was stimulated in 3T3L1 adipocytes by hypoxic microenvironments. Altogether, these data indicate that mGal-12 not only regulates adipogenesis but also angiogenesis in adipose tissue, highlighting a new potential target for development of specific therapies for obesity-related disorders.

Keywords: adipose tissue, Galectin-12, angiogenesis, Lewis X, hypoxia.

ONCOLOGY-ONCOIMMUNOLOGY 7

(190) **DOWN-REGULATION OF GALECTIN-8 AND ITS LIGAND ALCAM ("*ACTIVATED LEUKOCYTE CELL ADHESION MOLECULE*", CD166) REDUCES *IN VIVO* TUMOR GROWTH IN A MURINE MODEL OF BREAST CANCER.**

Fatima Eneida Del Valle Ferragut (1), Lucas Luis Colombo (2), Clara Sánchez Terrero (3), Vanina Vachetta (1), Carlota Wolfenstein-Todel (1), María Fernanda Troncoso (1), Gabriel Adrían Rabinovich (4), María Teresa Elola (1)

Galectin-8 (Gal-8) is a '*tandem-repeat*'-type galectin, with two carbohydrate recognition domains. We previously showed that the *activated leukocyte cell adhesion molecule* (ALCAM), which is a cell adhesion molecule, serves as a Gal-8 ligand. The aims of this work were: 1) To analyze cell surface effects of the Gal-8/ALCAM axis on adhesion and migration of human MDA-MB-231 breast cancer cells; 2) To investigate Gal-8 and ALCAM effects on cell proliferation and spheroid formation; 3) To evaluate Gal-8 and ALCAM effects in a murine model of breast cancer. We established MDA-MB-231 cell lines in which Gal-8 (MDA-shGal8) and/or ALCAM expression (MDA-shALCAM) were stably knocked-down with specific shRNA; scrambled-shRNA was used for controls (MDA-shControl). Our results showed that cell adhesion onto immobilized Gal-8 was significantly reduced after ALCAM silencing in MDA-shALCAM (26.3±7.0%) and MDA-shALCAM-shGal8 (25.6±6.8%) as compared to MDA-shControl cells (100%), $p<0.05$. In migration assays onto immobilized Gal-8, wound-closure percentages were significantly reduced after ALCAM silencing in MDA-shALCAM (23.2±1.3%) and MDA-shALCAM-shGal8 (22.8±1.2%) as compared to MDA-shControl cells (40.8±2.5%), $p<0.001$. ALCAM down-regulation, but not Gal-8 silencing, significantly reduced cell proliferation by MTT (MDA-shALCAM: 0.39±0.19 and MDA-shALCAM-shGal8: 0.38±0.03 versus MDA-shControl cells: 0.48±0.31, $p<0.001$) and spheroid volume (80%, $p<0.001$). Tumor growth in *nude* mice indicated that tumors generated by MDA-shALCAM, MDA-shGal8 and MDA-shALCAM-shGal8 cells were significantly smaller than those produced by MDA-shControl cells at 60 days post-inoculum ($p<0.05$); tumors derived from MDA-shALCAM-shGal8 (291.2±89.8 mm^3) showed smaller volume than those from MDA-shALCAM cells (1075.8±388.9 mm^3) ($p<0.05$) at 90 days. Our results demonstrate that there are ALCAM-Gal-8 interactions at the cell surface, and that depletion of Gal-8 and ALCAM delays primary tumor growth.

Keywords**:** Galectin-8, ALCAM, breast cancer.

(1188) **FIRST EVIDENCE OF CHANGES IN THE TCRB REPERTOIRE FROM A CUTANEOUS MELANOMA PATIENT IMMUNIZED WITH THE CSF-470 VACCINE**

Mariana Aris (1), Alicia Inés Bravo (2), María Betina Pampena (1), Paula Alejandra Blanco (1), Daniel Isaac Koile (3), Ibel Carri (4), Patricio Yankilevich (3), María Marcela Barrio* (1), José Mordoh* (1, 5)

Fundación Instituto Leloir-IIBBA-CONICET (CABA, Argentina)

We have developed the allogeneic vaccine CSF-470, tested in a Phase-II study for post-surgery adjuvant treatment in stage IIB-III patients (CASVAC-0401, NCT01729663). The aim of this work was to analyze the peripheral and tumor-associated immune infiltrate and the TCRβ immune repertoire in a cutaneous melanoma patient (#006) immunized with the CSF-470 vaccine that developed a cutaneous metastasis at the end of the 2-year protocol. *Methods:* PBMC at 0, 12, 24 and 48 months after protocol start, primary tumor and metastasis biopsies were obtained. Peripheral and tumor-associated immune populations were analyzed by flow cytometry and immunohistochemistry. CDR3-TCRβ sequencing of PBMC and metastasis was performed by NGS. *Results:* from immunization, a sharp increment of NK cells followed by an increase in $CD4^+$ and $CD8^+$ cells by the end of the protocol were detected in blood. Analysis of pre- and post-CSF-470 vaccine biopsies revealed a marked increase in $CD8^+$, $CD4^+$ and $CD20^+$ lymphocytes, with low Tregs. Regarding the TCRβ immune repertoire in blood throughout CSF-470 immunization, an increase in diversity and clonality was observed, as shown by a shift with expansion of selected pre-existing and new arising clones while diminution of others (n=125836). In tumor infiltrating lymphocytes (n=1382), the prevalent clones were the ones which were expanded after CSF-470 immunization, both new and pre-existing ones (50%). These clones persisted in time, since 2-years after completing immunization, 51% of the clones present in the resected metastasis were still detected in blood. *Conclusion:* this is the first report of the TCRβ repertoire from a cutaneous melanoma patient immunized with the CSF-470 vaccine. The immune population changes observed in peripheral blood as well as in the local compartment following immunization of this patient suggest that the CSF-470 vaccine induced a specific anti-tumor adaptive immune repertoire that reached the tumor lesions.

(1758) **IMMUNE CELLS ASSOCIATED TO LUNG METASTASIS CAN BE MODIFIED BY THE CONSUMPTION OF A PROBIOTIC FERMENTED MILK**

Virginia Emilce Méndez Utz, Alejandra De Moreno De Leblanc (1), Gabriela Perdigón (1)
(1) CERELA.

Lung metastases (MTS) are common from breast cancers. Immune cells associated to MTS can help tumor cell growth or can response against them. Previous studies showed that milk fermented by probiotic *Lactobacillus casei* CRL431 (PFM) modulated the immune response in mice bearing breast tumor and decreased tumor growth and MTS. The aim of this study was to evaluate the effect of PFM (administered after tumor surgery) against immune cells associated to lung MTS. Female BALB/c mice were injected 4T1 cells to induce breast tumors and when tumors reached volume near to $0.3cm^3$ were surgically removed. After that, mice were divided into 2 groups: one received PFM and the other, milk (M). Healthy mice given milk were used as control (C). Mice were euthanized (60d after tumor injection); the lungs were removed for histology and for the isolation of immune cells. Cells were cultured to measure cytokine releases after the in vitro stimulation with 4T1 cells or they were analyzed by flow cytometry to evaluate macrophages and $CD4^+$ and $CD8^+$ T lymphocytes. PFM administration diminished the nodes in the lungs compared to M group. Cells from lung of PFM group decreased significantly ($p<0.05$) the concentration of IL-10, TNFα and IL-6 (71.3±0.3; 363.7±20.2; 766.07±100) in culture supernatants compared to M group (118.4±6.5; 489.4±40; 2899.9±300). Macrophages decreased significantly ($p<0.05$) in PFM group (26.6%±3.6) compared to M group (50.5%±16.8), maintaining percentages similar to C group (27.5%± 2.14). PFM group showed the lowest percentage of $IL\text{-}10^+$ macrophages. The percentages of $IL\text{-}12^+$ macrophages and $CD8^+$ cells were similar in both PFM and M group. The highest percentages for $CD4^+$ and $CD4^+CD8^+$ cells were observed in PFM group. Conclusion: Consumption of PFM after tumor surgery decreased lung MTS by modulating the immune response in the lungs. The decrease of macrophages has a key role in this modulated response, especially through the reduction of IL-10 producing macrophages.

(911) **IMMUNE-CHECKPOINT INHIBITORS AND ANTI-TUMOR VACCINES SUPPORT THE IMMUNOSTIMULATORY THEORY OF CANCER**

Paula Chiarella (1), Daniela Montagna (1), Ariel Strazza (1), Monica Vermeulen (2), Raúl Ruggiero (1)
(1) Oncología Experimental - IMEX - CONICET - ANM Buenos Aires, (2) Inmunología Oncológica - IMEX - CONICET - ANM Buenos Aires

Immune-checkpoint inhibitors and antitumor vaccines produce tumor-inhibitory and stimulatory effects on growing tumors depending on the stage of tumor growth at which treatment was initiated. These paradoxical results can be understood by the immunosurveillance postulates but might be explained by the Immune Stimulatory Theory of Cancer, that was originally proposed on the basis that the immune response (IR) induced by immunogenic murine tumors was not monotonic but biphasic, with strong IR producing inhibition and weak IR inducing stimulation of tumor growth. In a previous work we have demonstrate that most spontaneous murine tumors (ST) studied grow in an accelerated way in pre-immunized hosts and more in immunodepressed mice; that the interaction of specifically-immune T cells and target tumor cells at low stimulatory ratios enhanced the production of rantes and MIP1α and when Winn tests were carried out in indomethacin-treated tumor bearing mice or TLR4KO tumor bearing mice, the stimulatory effect was not observed. We extended those observations to understand better the mechanism. We observed in ST an increase of PDL1 and an activation of TLR4 and p38 signaling pathways, which recruit more macrophages and other inflammatory cells that would produce pro-inflammatory cytokines, TNFα ($p<0.02$); IL1β ($p<0.01$) and IL6 ($p<0.02$), leading to an accelerated tumor growth ($p<0.05$). At medium and large-sized tumors, different anti-tumor immunological schedules were attempted therapeutically against a strongly-immunogenic MCC (low PDL1) and a weakly-antigenic LB (high PDL1): a) *Vaccines and immune-depressors p<0.05*, b) antiCTLA4 and/or antiPDL1 $p<0.01$, and c) *Counteraction of the tumor-immunostimulatory effects* (indomethacin or anti-p38), $p<0.01$. This produced a significant inhibition of tumor growth. These results were encouraging and could be an interesting contribution to the use and management of different types of immunological treatments against the tumor. **Key words:** murine tumors, immunostimulatory theory, immunosurveillance, anti-tumor vaccines, immune-checkpoints inhibitors.

(842) **IMMUNOMODULATORY ROLES OF HISTAMINE H4 RECEPTOR IN BREAST CANCER**

Helena Andrea Sterle (1), Melisa B. Nicoud (1, 2), Noelia A. Massari (3), Mónica A. Táquez Delgado (1), Ximena Hildebrandt (1), María V. Herrero Ducloux (3), Graciela A. Cremaschi (1, 2), Vanina A. Medina (1, 2)
(1) Instituto de Investigaciones Biomédicas (BIOMED, UCA-CONICET), Buenos Aires, Argentina, (2) Laboratorio de Radioisótopos, Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires Buenos Aires, Argentina, (3) Facultad de Ciencias Naturales y de la Salud, Universidad Nacional de la Patagonia San Juan Bosco, Chubut, Argentina.

Histamine regulates the growth and development of different types of tumors. Although the role of histamine H4 receptor (H4R) in immune cells is extensively investigated, its immunomodulatory function in cancer is completely unknown. This study aimed to investigate the role of H4R in antitumor immunity in a model of triple negative breast cancer (TNBC). We evaluated growth parameters, histological characteristics of tumors and the composition of tumor, splenic and tumor draining lymph nodes (TDLN) immune subsets in a syngeneic model TNBC developed orthotopically with 4T1 cells in H4R knockout (H4R-KO) and wild-type (WT) mice.

Mice lacking H4R show reduced tumor size and weight (1.6±0.2 g vs. 0.9±0.1 g, P=0.003) and decreased number of lung metastases. Tumors of H4R-KO mice exhibit a more differentiated histopathological pattern (grade 2) compared to WT mice (grade 3, highly aggressive potential) and display a significant decrease in the mitotic index

and angiogenesis. H4R-deficency is associated with a decrease in the percentage of $CD4^+$ tumor infiltrating T cells ($p<0.001$) and an increase of $CD19^+$ lymphocytes ($p<0.01$) and NK cells ($p<0.05$). A positive correlation was detected between the percentage of $CD8^+$ infiltrating T cells and tumor weight ($R=0.8924$, $p<0.05$) while MDSC negatively correlated with tumor growth ($R= -0.8862$, $p<0.05$) just in H4R-KO mice. Likewise, TDLN of H4R-KO mice show decreased CD4+ T cells ($p<0.05$), but increased percentage of NK cells ($p<0.05$). Tumor weight was negatively correlated with NK cells ($R=-0.8874$, $p<0.05$) as well as B lymphocytes ($R=-0.8604$, $p<0.05$), but positively correlated with CD8+ T cells ($R=0.7730$, $p<0.05$) in TDLN of H4R-KO mice.

These results suggest an interplay between H4R expressing immune cells in tumor microenvironment and cancer cells, which has implications in breast cancer progression.

Keywords: histamine H4 receptor, breast cancer, antitumor immunity

(935) **IMMUNOTHERAPY BASED ON THE TLR3 LIGAND POLY A:U MODIFIES THE TUMOUR-ASSOCIATED MYELOID COMPARTMENT UPREGULATING PDL1 SPECIFICALLY ON $MHCII^-$ MONOCYTES ON A TYPE I IFN-DEPENDANT MANNER**

Emiliano Roselli (1), Paula Araya (2), Nicolas Gonzalo Nuñez (2), Cinthia Stempin (1), Eliane Piaggio (3), Mariana Maccioni (1)

(1) CIBICI-Dpto.Bioquimica Clinica-FCQ-UNC, (2) University of Zurich - Institute of Experimental Immunology, (3) Institut Curie - U932 Laboratoire d'immunologie.

Poly A:U (pAU) is a synthetic dsRNA which signals through TLR3 to modulate an immune response by inducing the release of type I IFNs on a broad range of cells including cancer cells and tumour-associated myeloid populations. Relying on this, pAU can be exploited as an immune-adjuvant on cancer therapy to improve an antitumor immune response. In this work, we evaluated the effect of pAU treatment on a murine B16 melanoma cancer model focusing on the myeloid compartment, including tumour-associated macrophages (TAMs - $CD45^+$; $CD11b^+$; $F4/80^+$; $LyC6^-$; $CD24^-$), tumour-infiltrating DCs ($CD45^+$; $CD11b^+$; $CD24^+$; $CD11c^+$; $MHCII^+$), together with tumour-associated monocytes ($CD45^+$; $CD11b^+$; $Ly6C^+$; $CCR2^+$) which can be divided into MHCII+ and MHCII- monocytes. We demonstrated that a three-dose regime of intratumoral treatment with pAU (100µg/tumour) significantly decreases tumour size from 0.33g to 0.15g ($p<0.05$) compared to PBS-treated mice. Within tumour-infiltrating leukocytes, plasticity and cell polarization of TAMs are key aspects to define a final antitumoral (M1-like) or protumoral (M2-like) outcome and here we observed that pAU significantly decreases the total number of M1-like macrophages ($MHCII^{high}$; CD206-) and M2-like macrophages ($MHCII^{low}$; CD206+) the latter being the population accounting for most of the intratumoral IL10 production as seen by FACS. We determined that both MHCII+ and MHCII- monocytes were a key source of intratumoral TNFα, which was upregulated after pAU treatment ($p<0.05$). Strikingly, when we evaluated the expression of PDL1, expressed by APCs and tumour cells, we observed a significant upregulation ($p<0.05$) of this ligand specifically on MHCII- monocytes after the treatment with pAU and very little impact on other tumour-infiltrating cells. Finally, most of the effects described after pAU administration on the myeloid compartment were lost in IFNAR-/- mice, suggesting that pAU-induced type I IFNs directly modulate myeloid cells in the tumour.

Abstract: BRAF is mutated in 50% of melanoma patients. BRAF is a component of the RAS/RAF/MEK/ERK pathway and BRAF or MEK inhibitors increase progression-free and overall survival in BRAF- mutant patients. However, most patients relapse with acquired resistance and ~20% of patients present intrinsic resistance. Preclinical and translational studies have shown that targeting the RAS/BRAF/MEK/ERK pathway has effects on the expression of immunomodulatory pathways. Macrophages are key players within the tumor microenvironment and their functional profiles control responses to a variety of therapies. Whereas M1 macrophages efficiently present antigens to T cells and promote tumor destruction, M2 macrophages promote tumor progression, immune evasion and angiogenesis. Most patients who develop resistance to targeted therapies derive little benefit from anti-CTLA-4 and anti PD-1 based immunotherapies. Our preliminary findings based on glycophenotyping, transcriptomics data analysis, western blotting and functional studies show changes in the galectin/glycan axis in melanoma resistance to BRAF inhibitors (BRAFi). Particularly we found in patient tumor biopsies collected prior to and on/following treatment with the BRAFi vemurafenib that M2 macrophage density (as defined by CD163+/CD68+) was increased after treatment ($p=0.02$, $n=7$). Initial *in vitro* data supports a direct interaction between tumor cells and peripheral blood monocytes, with BRAF inhibitor-resistant cells driving monocyte differentiation towards a CD163+ phenotype. Moreover, the glycosylation profile of BRAFi resistant cells show an increase in asialo core 1 O-glycans and augmented levels of polylactosamines. Additionally, resistance to BRAFi decreases α(2,6) sialylation levels ($n=3$, $p<0,05$). We hypothesize that there are specific galectin/glycan interactions that could be the drivers of an M2-macrophage immunosuppressive microenvironment in the resistant tumors preventing response to immunotherapy treatment.

Glioblastoma multiforme (GBM) is the deadliest and most common type of human primary brain tumor. This tumor is defined by the hallmark features of uncontrolled cellular proliferation, diffuse infiltration, robust angiogenesis, resistance to apoptosis and genomic instability. Acetylcholine is a neurotransmitter which can also modulates cell survival, proliferation and differentiation in neuronal and non-neuronal cells such as immune cells, which has been referred to as a "non-neuronal cholinergic system". The aim of this work was to elucidate the relevance of the non-neuronal cholinergic system in the interaction between immune and GBM cells. We first evaluated the expression of acetylcholine receptors in human GBM cell lines by fluorescence microscopy. We found that both U251 and U373 human GBM cells express acetylcholine muscarinic receptors M1 and M3. In order to evaluate whether the cholinergic system affects the cross-talk with immune cells, human U251 cells were co-cultured

with human dendritic cells (DC) in the presence of cholinergic agonists (carbachol and muscarine). Mononuclear cells were isolated from buffy coats of healthy adult nonsmoker volunteer and CD14+ cells were then isolated by positive selection and then were cultured with GM-CSF and IL-4. The co-cultures were incubated in the presence of carbachol 10^{-8} M) and muscarine (10^{-8}M). We found that U251 cells upregulated the expression of CD86 in DCs as assessed by flow cytometry in presence of carbachol and muscarine with respect to control co-cultures ($p<0.05$). Human U251 and U373 GBM cells were cultured in presence of a cholinergic agonist (carbachol) to evaluate their expression of the coactivation marker ligand OX40 ligand (OX40L) as assessed by flow cytometry, but no differences were observed between the cells treated with carbachol and controls. Conclusions: our findings suggest that the non-neuronal cholinergic system is present in GBM cells and could modulate their cross-talk with the immune system.

(142) **ROLE OF RET RECEPTOR TYROSINE KINASE AT THE POST-LACTATIONAL TRANSITION, A WINDOW OF NORMAL MAMMARY GLAND DEVELOPMENT WITH HIGH INFLAMMATION AND CANCER POTENTIAL**

Under the influence of hormones, the mammary gland undergoes repeated cycles of proliferation, differentiation at lactation, and regression to involution, a process through the gland reverts back to virgin females. Those changes permanently alter the morphology/molecular characteristics of the breast and lead to important, yet poorly understood changes in cancer risk. Her2, a member of the receptor tyrosine kinases (RTK) family is well known to promote aggressive breast cancers. We have reported that Ret, another RTK member, is overexpressed in about 40% of human tumors. It is well known that RTKs, e.g. the Her2, also have roles in normal breast, but nothing is known about the function of Ret. We found that Ret is highly expressed in the mouse glands during mid-lactation. Blocking Ret activity in lactation by in vivo administration of Ret inhibitor reduces pup size, suggesting its potential role in this period.

We generated a mouse strain (Ret/MTB) with the MMTV mammary gland specific promoter controlling Ret expression in an inducible system, allowing induction of Ret by feeding mice with doxycycline. We found that abnormal Ret overexpression outside of the lactation, leads to the development of tumors that recapitulates human luminal carcinoma, with an inflammatory component and an active Stat signaling (phospho-Stat1/3). Since Ret expression can be turned-on in an inducible manner, we used this model to express Ret at different developmental stages. Indeed, Ret appears to have a role in the post-lactation transition to involution. When Ret is induced early in lactation we observe enhanced kinetics of involution. The involution period is well known to drive cancer progression. By RNA-seq we found that Stat signature is increased in Ret-overexpressing glands, which was confirmed by several techniques. Thus, our results suggest that if Ret expression is deregulated during the post-lactational transition this might contribute to breast cancer development.

Chronic Lymphocytic Leukemia (CLL) is a disease characterized by the clonal proliferation and accumulation of mature, typically CD5-positive B-cells within the blood, bone marrow, lymph nodes, and spleen. Leukemic transformation is initiated by alterations that impair apoptosis of clonal B-cells and the pathways engaged in programmed cell death involve several Bcl-2 family proteins. It has been described that Bcl-2–family proteins may regulate autophagy. This degradative pathway has dual role in cancer depending of the type of tumor. Therefore, autophagy can be exploited for promote survival, or cell death, as well. Whereas autophagy can be regulated by Toll like receptors (TLRs), and these receptors participate in the CLL progressive pathogenesis, we hypothesize that TLR2 activation modulate autophagy in CLL cells. This effect may influence the expression of genes and proteins involved in CLL pathogenesis. We analyzed LC3B expression in peripheral blood mononuclear cells isolated from CLL-patients. Pam3CSK4 (TLR2 ligand) induced increased LC3B II expression in CLL cells and this effect was potentiated by co-stimulation with Pam3CSK4 plus Fludarabine. Interestingly, Pam3CSK4 modulated CLL cell death induced by Fludarabine.

On the other hand, MDP (ligand for the innate immunity receptor NOD2) induced similar effects on CLL cells.

These preliminary results suggest that innate receptors may affect autophagy and leukemia cell survival.

(298) **ANTI-TUMOR ACTIONS OF PACLITAXEL PLUS CARBACOL ON HUMAN TRIPLE NEGATIVE BREAST CANCER CELLS**

Agustina Salem, Yamila Sanchez, María Elena Sales, Alejandro Español
CEFYBO-UBA-CONICET

Abstract: The administration of low doses of cytotoxic drugs alone or combined with repurposing drugs scheduled with short inter-dose intervals is called metronomic therapy (MT). MT is a new strategy in cancer treatment, since it exhibits high effectiveness and low incidence of side effects. The most aggressive type among human breast tumors is triple negative (TN), probably due to the absence of a specific target for pharmacological treatment. Here, we analyzed the effect of a combination of subthreshold concentrations of carbachol (CARB) (10^{-12}M) with paclitaxel (PX) (10^{-8}M) on MDA-MB231 cell line derived from a TN breast cancer patient during 40 h. By MTT assay we observed that the addition of 10-6M PX, a concentration similar to that used in conventional chemotherapy increased tumor cell death by 40±2% ($p<0.001$ vs. control) but also increased by 33±2% ($p<0.001$ vs. control) cell death in non-tumorigenic mammary cells MCF-10A. On the other hand, the combination of CARB with PX increased cytotoxicity by 27±3% ($p<0.01$ vs. control) without affecting MCF-10A viability. In addition, CARB plus PX reduced MDA-MB231 tumor-induced neovascularization (N°vessels/mm^2 skin) in nude mice skin (skin: 3.17±0.05; tumor: 4.14±0.23 $p<0.001$ vs. skin; tumor+CARB+PX: 3.16±0.35 $p<0.001$ vs. tumor) and the expression of vascular endothelial growth factor-A in tumor cells ($p<0.05$). Using a xenogeneic model, nude mice were inoculated with MDA-MB231 tumor cells ($3x10^6$) in the left flank and after tumor palpation, animals were treated with CARB plus. PX (i.p.). The combination significantly reduced tumor growth in relation to control (untreated mice; $p<0.001$). These results suggest that CARB plus PX at low doses could be a new strategy to treat TN breast tumors in humans.

Keywords: cancer; metronomic-therapy; angiogenesis

(1522) **ANTITUMORAL AND ANTIMETASTATIC ACTIVITY OF MAITAKE D-FRACTION IN TRIPLE-NEGATIVE BREAST CANCER CELLS.**

Eliana Noelia Alonso, María Julia Ferronato, Norberto Ariel Gandini, María Eugenia Fermento, Josefina Alejandra Guevara, Florencia Mariani, María Marta Facchinetti, Alejan-

dro Carlos Curino
Laboratorio de Biología Del Cáncer, Instituto de Investigaciones Bioquímicas de Bahía Blanca (INIBIBB), Universidad Nacional del Sur (UNS) Conicet, Departamento de Biología, Bioquímica y Farmacia (UNS), Bahía Blanca, Argentina

D-Fraction is a proteoglucan extracted from *Grifola frondosa* (Maitake) mushroom. Previously, we reported that D-Fraction decreases breast cancer (BC) cell viability regardless of hormone receptors and HER2 status of cells. Furthermore, D-Fraction reduces tumor burden and lung metastases in a murine model with hormone-independent LM3 cells. In triple-negative (TNBC) MDA-MB-231 cells, we also demonstrated that D-Fraction decreases their migration and invasion capacity. The purpose of the current study is to identify the cellular and molecular mechanisms by which D-Fraction decreases the migratory/invasive potential of MDA-MB-231 cells. In addition, we propose to evaluate the antitumoral effect of D-Fraction in 4T1 cells, another cell line representative of TNBC subtype. By western blot, we found that D-Fraction increases E-cadherin expression in MDA-MB-231 cells compared to vehicle treatment ($p<0.05$). By immunofluorescence, we detected that D-Fraction decreases the presence of β-catenin in the cytoplasm/nucleus ($p<0.001$) and promotes its membrane localization ($p<0.01$). Also, we found that D-Fraction increases the adhesion of MDA-MB-231 cells to substrate ($p<0.05$). By zymography, we detected that D-Fraction decreases MMP-2 and MMP-9 activity by 53.59 % ($p<0.001$) and 27.31 % ($p<0.05$) respectively, compared to vehicle treatment. On the other hand, manual cell counting and WST-1 assay were performed in TNBC 4T1 cells. D-Fraction decreases the viability of 4T1 cells in a dose- and time-dependent manner ($p<0.05$). Wound healing assay demonstrated that D-Fraction decreases the migratory capability of 4T1 cells ($p<0.001$). By transwell Matrigel assay, D-Fraction reduces the invasive capability of these cells ($p<0.001$). In conclusion, our results suggest that D-Fraction decreases the viability and metastatic potential of TNBC cells: promoting an epithelial phenotype; reducing the capability of tumor cells to degrade extracellular matrix and increasing cell-substrate adhesion.

Keywords: D-Fraction, Maitake, triple-negative breast cancer, antitumoral, antimetastatic.

(1332) **CDC42 REVERTS AGGRESSIVENESS OF A TRIPLE NEGATIVE BREAST CANCER CELL LINE TROUGH METHYLATION OF ID4 PROMOTER**

Daniela Lucia Nasif, Sergio Laurito, Emanuel Campoy, María Roqué Moreno, María Teresita Branham
IHEM-CONICET

Breast cancer constitutes a group of diseases characterized by different morphologies and biological behaviors. Molecularly they can be classified as luminal A, luminal B, human epidermal growth factor receptor 2, and triple-negative breast cancers (TN); lacking ER/PR/HER2. Clinically, the TN subtype has an aggressive nature, higher rates of relapse and shorter overall survival. TN tumors affect younger patients and are more prevalent in African-American and Latin women. Cdc42 is a plasma membrane-associated small GTPase which is involved in the regulation of several cellular functions and its expression is dysregulated in several tumor types. Here we show that Cdc42 overexpression reduced TN aggressive phenotype through the methylation of ID4 (inhibitor of Differentiation) promoter. Briefly, MDA-MB321 cell lines were transfected with a Cdc42-GFP vector and afterwards ID4 methylation status was measured by droplet digital and conventional Methyl Specific PCR. MS-MLPA assay revealed that ID4 methylation increased significantly in the Cdc42 transfected cells and interestingly, the methylation values of other genes remained unchanged. WB assay revealed that ID4 protein expression decreased after cdc42 transfection. Since ID4 inversely regulates BRCA1 expression in breast tumors, we evaluated BRCA1 status after transfection. Our results show that BRCA1 protein expression increased in the Cdc42 transfected cells. Migration and Apoptosis assays by wound healing and flow cytometry determined that the transfected cells migrated less ($p<0,001$) and had increased apoptosis ($p<0.05$), in line with a reduction in aggressive behavior. In silico studies from TCGA data revealed that Cdc42 expression was significantly associated with the expressions of: HDAC3, MBD2, MBD1 and YY1. Remarkably, all these genes participate in the regulation of gene transcription. Taken together our results show that cdc42 induces ID4 methylation and reverts aggressiveness in a TN cell line.

Key words: Triple negative breast cancer; Cdc42; Methylation; ID4

(1857) **CROSS-TALK BETWEEN ANDROGEN RECEPTOR AND ErbB-2 SIGNALING PATHWAYS IN TRIPLE-NEGATIVE BREAST CANCER**

Mariela Lenze, Florencia Chervo, Mauro Cenciarini, Santiago Madera, Mara De Martino, Sofía Bruni, Florencia Mercogliano , Roxana Schillaci, Rosalía Cordo Russo, Cecilia Proietti, Patricia Elizalde
Laboratorio de Mecanismos Moleculares de Carcinogénesis, Instituto de Biología y Medicina Experimental, Ciudad Autónoma de Buenos Aires, Argentina.

Triple negative breast cancer (TNBC) encompasses tumors without clinically significant levels of estrogen/progesterone receptors and membrane ErbB-2 (MErbB-2) overexpression or gene amplification. TNBC tumors have poor prognosis and neither established biomarkers nor therapeutic targets. On the one hand, we and others have shown that MErbB-2 (tyrosine kinase receptor) migrates to the nucleus of BC cells (nuclear ErbB-2, NErbB-2) where it binds to promoters/enhancers of target genes to regulate BC proliferation and migration. Interestingly, we have previously shown that NErbB-2 is required for in vitro and in vivo TNBC growth. On the other hand, several reports have proposed the androgen receptor (AR), another member of the steroid receptor superfamily, as a new target in TNBC. AR is expressed in 10-53% of TNBC and was proved to be critical for BC proliferation. We and others have shown a functional interplay between growth factors and steroid hormone receptors signaling pathways in BC. We propose the existence of a cross-talk between AR and ErbB-2 signaling pathways which regulates the expression of genes involved in TNBC growth. The experimental model used was the human TNBC cell line MDA-MB-453 which displays high expression levels of AR and NErBb-2. By Western Blot, we evidenced that dihydrotestosterone (DHT) treatment for short times (minutes) induced tyrosine phosphorylation of ErBb-2 (at residues 877, 1221/1222 and 1248). By confocal microscopy, we observed that DHT also induced ErBb-2 and AR nuclear translocation and co-localization. Finally, both DHT and HRG (heregulin, one of the ErbBs' ligands) up-regulated Erk5 protein levels, an ErBb-2 target gene that we have previously shown to be involved in BC proliferation. Our findings evidence that DHT-activated AR induces ErbB-2 rapid activation, nuclear translocation and co-localization, suggesting a functional cross-talk between both receptors which drives Erk5 regulation.

Keywords: androgen receptor, NErBb-2, cross-talk, TNBC.

(1794) **SUBCELLULAR DISTRIBUTION OF BETA-CATENIN IN CISPLATIN-TREATED TRIPLE NEGATIVE BREAST CANCER CELLS**

María Evelyn Cordoba (1), Gisela Pennacchio (1), Mariángeles Ávila Maniero (1,2), Laura Vargas-Roig (1), Silvina Nadin (1), Mariel Fanelli (1)
(1) IMBECU. (2) QUIANID.

Triple negative breast cancer subtype (TNBC) accounts for about 15-20% of all invasive breast tumors. TNBC lacks expression of estrogen receptor (ER), progesterone receptor (PR) and Epidermal Growth Factor type 2 Receptor (HER2). To date not a single therapy has been applied, conventional cytotoxic chemotherapy is currently the only treatment option for TNBC. Unfortunately, some patients respond but others become resistant or eventually relapse. New therapeutic approaches are focused in the search of other molecular target and anticancer drugs not classically used for breast cancer treatment, such as platinum analogues (cisplatin). Aberrant expression of beta-catenin has been linked to tumor progression and has become a promising target for cancer therapy. The aim of this work was to study the functionality of beta-catenin exposed to cisplatin in human cell lines, MDA-MB231 (TN) and MCF10A (non-

tumorigenic epithelial cell line). Cisplatin toxicity was evaluated by MTT. The localization of total and active beta-catenin was analyzed by confocal microscopy and the expression levels by WB. The IC50 doses for MDA-MB231 and MCF10A were 91,48μM and 55,80μM, respectively. Cisplatin treatment induced localization of total and active beta-catenin from the plasmatic membrane/cytoplasm to the nucleus in MDA-MB231, but no changes were observed in MCF10A cells. Expression levels of total and active beta-catenin decreased significantly ($p \leq 0,05$) with cisplatin exposure in MDA-MB231 cells whereas the levels of these proteins were not significantly modified in MCF10A cells. Our preliminary data show altered subcellular localization and expression levels of beta-catenin by cisplatin in TNBC cells.

Key words: cisplatin, beta-catenin, triple negative breast cancer, subcellular distribution

(1643) **RUNX1 GENE EXPRESSION REGULATION IN TRIPLE NEGATIVE BREAST CANCER**

Sofía María Sosa (1), María Virginia Dansey (2), Santiago Rodriguez Segui (1,3), Natalia Rubinstein (1,3)
(1) IFIBYNE-CONICET. (2) UMYMFOR-CONICET, QB-FCEN. (3) DFBMC-FCEN.

Triple negative breast cancer (TNBC) is a heterogeneous group of diseases associated with early recurrence and low survival rates. Treatment options are limited due to the lack of specific therapeutic targets and are consequently managed with standard chemotherapy. Additionally, TNBC is associated with epithelial-mesenchymal transition (EMT). EMT is considered a process implicated in the metastatic cascade involving cellular conversion toward an invasive cell type and recent evidences strongly suggest that EMT process might be involved in tumor chemoresistance. It was found that RUNX1 protein expression correlates with poor prognosis in TNBC patients. Results from our group demonstrate that RUNX1 protein is able to up regulate the expression of RSPO3 (oncogene) and down regulate GJA1 (tumor suppressor gene) on TNBC cell lines. We demonstrate that RUNX1 is necessary for mammary tumor cell migration. Our main goal was to evaluate how RUNX1 gene expression is regulated in TNBC. Here we show that RUNX1 gene expression and transcriptional activity is significantly up regulated in Py2T after TGFβ treatment ($p<0.05$), and could be responsible of EMT in TNBC. To study how RUNX1 gene expression could be regulated we explored and found several DNA binding sites for the glucocorticoid receptor (GR) in silico. RUNX1 expression was significantly up regulated after dexamethasone (GR agonist) treatment on Py2T and MDA-MB-231 ($p<0,05$). Furthermore, RUNX1 gene expression was significantly downregulated after mifepristone (GR antagonist) treatment on the same cells ($p<0,05$). Interestingly, mifespristone has been described as a potential adjuvant in TNBC treatment. Here we propose a novel way to regulate RUNX1 expression, aiming at sensitizing tumor cells to known synthetic drugs. These data strongly suggests that **RUNX1 could be responsible of EMT and a potential target of GR** and, after further research**,** we could be able to find **a new therapeutic target to control TNBC progression.**

Keywords: TNBC, RUNX1, GR, EMT

(462) **RUNX2 REGULATES THE HORMONE REQUIREMENT AND THE METASTATIC / POTENTIAL OF T47D BREAST CANCER CELLS *IN VIVO*.**

María Sol Rodriguez, Claudia Lanari, Cecilia Pérez Piñero
Laboratorio de Carcinogénesis Hormonal, Instituto de Bilogía y Medicina Experimental-CONICET

Abstract: We have previously shown that FGF2 increases the proliferation of MCF-7 and T47D breast cancer cells activating FGFR2, progesterone and estrogen receptors alpha (PR and ERα respectively). It has been reported that FGF2 increases RUNX2 expression in bone cells and few reports suggest that this might also occur in breast cancer cells. Since high RUNX2 levels were detected in murine mammary carcinomas which acquired a hormone independent phenotype, we are currently exploring the role of the FGF2-FGFR-RUNX2 axis in breast cancer progression.

The aim of this study was to evaluate if RUNX2 overexpression was able to bypass the hormone requirement of non metastatic T47D breast cancer xenografts which express ERα and PR. We stably transfected T47D cells with an expression plasmid carrying RUNX2 (RUNX2 cells) or with the empty vector (control cells). RUNX2 cells showed an increase in FGFR2 and FGF2 expression, supporting the hypothesis that FGF2 increases RUNX2, and RUNX2, in turn increases FGF2 expression, maintaining a positive loop. Both cell types were s.c. inoculated with Geltrex into the flank of NSG mice in the presence or absence of 17-β-Estradiol (E2 pellets; 0.5 mg). In untreated mice, only RUNX2 cells proved to be tumorigenic, although tumors remained with small sizes during the experiment. In E2-treated mice, RUNX2 xenografts grew faster and with a more aggressive phenotype as compared with control tumors ($p<0.001$). Lung metastases were only encountered in mice bearing the RUNX2 xenografts. To evaluate endocrine responsiveness, RUNX2 xenografts growing in E2-treated mice, were treated with Fulvestrant (0.5mg/week) or MFP (6 mg pellets). RUNX2 tumors did not respond to endocrine therapy and all animals showed lung metastasis. We conclude that RUNX2 promotes tumor progression and it may play a role in the acquisition of endocrine resistance. Further studies are required to elucidate the role of FGF2/FGFR2 in the establishment of this phenotype.

Keywords: RUNX2, FGF2/FGFR2 axis, metastasis, breast cancer.

(685) **THE FLAVONOID 2'NITROFLAVONE SUPPRESSES HUMAN TRIPLE-NEGATIVE BREAST CANCER CELL GROWTH *IN VITRO***

Vanina Sol Vachetta, Fatima Ferragut, Pablo Carabias, Mariel Marder, Maria Teresa Elola, Maria Fernanda Troncoso
IQUIFIB, Facultad de Farmacia y Bioquímica, UBA.

Abstract: In addition to the human epidermal growth factor receptor 2 (HER2)-positive subtype, triple-negative breast cancer (TNBC) is one of the most aggressive subtype of mammary tumor. Owing to its lack of estrogen receptor, progesterone receptor and HER2, neither endocrine nor anti-HER2 molecular targeting therapy yield promising results, and standard chemotherapy is the backbone of systemic treatment. Flavonoids are a group of polyphenolic compounds considered potential chemopreventive candidates for cancer treatment. Previously, we synthesized the flavonoid 2'nitroflavone (2'NF) and it was demonstrated to induce LM3 murine mammary adenocarcinoma cell apoptosis and to act as an anti-tumor agent *in vivo*. Our aim was to evaluate 2'NF effect on human TNBC cell growth *in vitro*. 2'NF exerted a dose- and time-dependent inhibitory effect on MDA-MB-231 and MDA-MB-468 cells (MTT assay). The half maximal inhibitory concentration (IC_{50}) was 3.13±0.39 and 6.97±1.37% μM at 72h for MDA-MB-231 and MDA-MB-468 cells, respectively. Maximal inhibition of MDA-MB-231 cell growth (66.27±5.24%, vehicle control: 100% $p<0.001$) was obtained at 10 μM after 72h-treatment with 2'NF (higher concentrations produced a similar effect). For MDA-MB-468 cells maximal inhibition of cell viability (94.16±1.14% $p<0.001$) was obtained after incubation with 40 μM 2'NF for 72 h. Using clonogenic survival assays in MDA-MB-231 and MDA-MB-468 cells treated with 1.25 μM 2'NF for 10 days, colony formation rendered 66±21 and 65±2% respectively, as compared to the corresponding control cells (100%). In conclusion, 2'NF inhibited MDA-MB-231 and MDA-MB-468 cell growth *in vitro*. Thus, we propose 2'NF as a novel potential candidate for TNBC therapy.

Supported by CONICET (PUE-046).

(237) **TRISTETRAPROLIN (TTP) PROMOTES SURVIVAL OF HC11 MAMMARY EPITHELIAL CELLS**

Micaela Nadia Stedile (1), Goddio María Victoria (1), Lourdes Pérez Cuervo (2), Carolina Shere Levy (1), Edith Kordon (1, 2)
Instituto de Fisiología, Biología Molecular y Neurociencias (IFIBYNE). (2) Departamento de Química Biológica FCEN – UBA.

A common feature among relevant RNAs in mammary gland cancer is the presence of sequences enriched in adenine and uracil (AREs) situated in 3´untranslated regions (3´UTR). The stability of

RNAs with AREs is regulated by proteins that bind these regions, like tristetraprolin (TTP). This protein promotes degradation of mRNAs with AREs in their 3´UTR such as proinflammatory cytokines and invasiveness-associated factors.

We have previously reported that TTP is expressed in the mammary gland, reaching the highest levels during lactation. More recently, in conditional TTP-***knockout*** mice in which expression of this protein is down-regulated specifically during lactation, we found increased cell death and augmented expression of inflammatory cytokines in the secretory epithelium. We concluded that TTP expression is required for lactation maintenance.

Then, to determine whether this protein is also relevant for the survival of undifferentiated mammary cells, we analyzed cell viability of HC11 clones that were stably transfected with specific TTP-shRNAs (TTP-KD cells). Using the 3-(4,5-dimethylthiazol-2-yl)-5(3-carboxymethonyphenol)-2-(4-sulfophenyl)-2H-tetrazolium (MTS) assay, we determined that TTP-KD cells were less viable ($p<0,001$) than HC11 control cells, stably transfected with sh-scramble sequences (control cells). Similar results were obtained in the presence or absence of epidermal growth factor (EGF) or steroids in the culture medium. In addition, it was determined that the diminished viability could be, at least partially explained by the increase ($p<0,001$) of spontaneous apoptosis (analyzed by TUNEL assay) associated with higher levels of Bax protein ($p<0,001$), tested by Western Blot, in TTP-KD vs. control cells.

Taking together, these results indicate that TTP expression is relevant for both differentiated and undifferentiated mammary cell survival. We are presently analyzing the mechanisms underlying this effect.

Key words: HC11, tristetraprolin, cell survival, apoptosis

(1388) **ANTIPROLIFERATIVE EFFECT OF THE COMBINATION OF 2´NITROFLAVONE AND SAFINGOL IN MAMMARY TUMOR CELLS**

Florencia Celeste Gentilcore, Mariel Marder, Leonor Roguin, Julieta Marino, Viviana Blank

*Instituto de Química y Fisicoquí*mica Biológicas, Departamento de Química Biológica, Facultad de Farmacia y Bioquímica, Universidad d*e Buenos Aires*

In a previous work, we have demonstrated that the synthetic flavonoid 2´nitroflavone (2´NF), obtained in our lab, inhibited tumor growth by inducing apoptosis *in vitro* and *in vivo* in the murine mammary tumor model LM3. Some authors have proved that certain flavonoids induce apoptosis through an increase in the amount of ceramides. It has also been reported that the sphingosine kinase inhibitor safingol prevents ceramide catabolism, contributing to tumor cell death. Based on these results, in the search of new drug combinations that enhance the effect of each drug, we decided to explore the antiproliferative effect of the combination of 2´NF and safingol in LM3 cells. Cells were incubated with different concentrations of 2´NF and safingol alone or combined for 48 or 72h. IC_{50} values were 21±3 µM (48h) and 8±1 µM (72h) for 2´NF, and 1.4±0.5 µM (48h) and 1.1±0.4 µM (72h) for safingol. Proliferation of NMuMG normal murine mammary cells was not affected after 72h of incubation with concentrations of 50 µM (2´NF) or 5 µM (safingol). In order to quantitatively characterize the interaction between 2´NF and safingol, dose-effect curves were analyzed by Compusyn software. Results obtained showed that combination indexes were 0.72±0.06 (48h) and 0.71±0.01 (72h), indicative of synergism, in cells incubated with 5 µM of 2´NF and 0.6 µM of safingol. Additionally, when cells were treated with the same drug combination for 24h, an increase in the number of cells with apoptotic characteristics was observed by fluorescence microscopy after ethidium bromide and acridine orange staining. Furthermore, an increment of hypodiploid cells was detected by flow cytometry analysis. In conclusion, we demonstrated that a specific combination of safingol and 2´NF synergistically inhibited mammary tumor cell proliferation. This finding encourage us to study the molecular mechanisms involved in this effect and to consider this drug combination as a potential therapy for mammary cancer treatment.

(318) **TRANSMEMBRANE-DOMAIN SHAPE IS A NOVEL ENDOCYTOSIS SIGNAL FOR SINGLE-SPANNING MEMBRANE PROTEINS**

Ayelén Gonzalez Montoro, Gonzalo Bigliani, Javier Valdez Taubas

Depto. Química Biológica, CIQUIBIC, CONICET, Fac. de Cs Químicas, Univ. Nac. de Córdoba

Endocytosis is crucial for all cells as it allows them to incorporate material from the extracellular space and control the availability of transmembrane proteins in the plasma membrane. The classical model for endocytosis of membrane proteins involves cytosolic signals that interact with adaptor proteins, driving active concentration of cargo in endocytic vesicles. In yeast, endocytosis followed by recycling to the plasma membrane results in a polarised distribution of membrane proteins by a kinetic mechanism. Here we report that increasing the volume of the residues that constitute the exoplasmic half of the transmembrane domain in the yeast SNARE Sso1, results in its polarised distribution at the plasma membrane. Expression of this chimera in strains affected in either endocytosis or recycling revealed that this polarisation is achieved by endocytic cycling. A bioinformatics search of the *Saccharomyces cerevisiae* proteome identified several proteins with high-volume exoplasmic hemi-TMDs. Our experiments indicate that TMDs of these proteins can confer a polarised distribution to the Sso1 cytoplasmic domain, indicating that the shape of the TMD can act as a novel endocytosis and polarity signal *in yeast.* Additionally, high-volume exoplasmic hemi-TMDs can act as an endocytosis signal in mammalian cells in culture.

(556) **ATP RELEASE DEPENDS ON AUTOPHAGIC STIMULATION AND RAB21 IN HELA CELLS**

María Carolina Barbosa (1), Sebastién Nola (2), Thierry Galli (2), María Isabel Colombo (1), Claudio Marcelo Fader Kaiser (1)

ATP exocytosis has emerged as an important autocrine/paracrine signal to trigger responses regarding platelet aggregation, inter-astrocytes communication, cell migration, differentiation, etc. The molecular mechanisms underlying this process have not been well defined so far. In addition, autophagy-dependent ATP release was shown to be an important process involved in immunogenic cell death and inflammation. Autophagic exocytosis has been also implicated in IL-1β, IL-18, galectin-3 secretion and presentation of antigens to the major histocompatibility complex. The regulation of this process is poorly understood. Our group has previously shown that there is an important role of the v-SNARE protein VAMP7 in the autophagic ATP exocytosis. Since there is a close connection between VAMP7, the small GTP-ase Rab21 and autophagy we decided to investigate the role of this Rab protein, its guanine-nucleotide exchange factor VARP and another Rab related to VARP (Rab32) in the autophagic exocytosis of ATP. HeLa cells were transiently transfected with GFP-Vector, YFP-Rab32wt, YFP-Rab32T39N (negative dominant mutant), GFP-Rab21wt, GFP-Rab21T33N (negative dominant mutant) and/or RFP-LC3. Then we incubated this cells in full medium, resveratrol 50nM and rapamycin 50nM for 4 hours or starvation medium for 2 hours. We used LC3B or VARP antibodies to detect endogenous proteins. Lysotracker red was put 30 minutes before the incubation finished. For ATP release assays, we used the luciferin-luciferase kit to measure the amounts of ATP in the extracellular medium. We took samples at 0, 30, 60, 90, 120, 180 and 240 minutes after the autophagic stimulus began. We found that autophagy leads to a redistribution of Rab32 or Rab21 molecules to the cell periphery, where they colocalized with LC3 and VARP. ATP release was significantly increased in starvation and in less content

in resveratrol condition. Our results suggest a role for Rab21, Rab32 and VARP in the autophagic exocytosis of ATP.

Keywords: Rab21, ATP release, Autophagy, Rab32, VARP

Maria Celeste Gauron (1), Maria Isabel Colombo (1)
(1) Instituto de Histología y Embriología de Mendoza, CONICET, FCM, UNCuyo. Mendoza. Argentina.

Staphylococcus aureus is a microorganism that causes serious diseases in humans and it is known to induce an autophagic response in the host cell upon infection. We have previously demonstrated that the virulence factor a-hemolysin (Hla) is responsible of this autophagic response and it is used by the microorganism for escaping from its containing phagosome labelled with the autophagic protein LC3. We have further demonstrated that the autophagy induced by this bacterium is independent of the canonical PI3K/Beclin1 pathway and, instead, it is regulated by an AMPc/Epac/Rap2b pathway. In the current work we studied the implication of this pathway in the maturation of the *S. aureus* phagosome. We have found that treatment of infected cells with the second messenger cAMP, besides of regulating the autophagic response induced by *S. aureus,* also regulates its phagosome maturation by altering the recruitment of the small GTPase Rab7. We further found that the cAMP analogue, 8pCPT, which is able to specifically activate Epac1 also alters Rab7 association to the *S. aureus* phagosome. Likewise, overexpression of YFP-Epac1 itself has the same inhibitory effect. However, when we analyzed the effects of Rap2b, a downstream target of Epac1, the recruitment of Rab7 wasn't impaired. Therefore, our results indicates that cAMP regulates the maturation of the *S. aureus*-containing compartment in an Epac dependent but Rap2b independent-manner suggesting that other effectors might be involved.

Keywords: Staphylococcus aureus, phagosome, Rab7, cAMP.

(793) **THE *C. elegans* DAUER LARVA UNCOVERS A ROLE FOR CHD7/8 IN AUTOPAGHY REGULATION**

Diego Martin Jofre (1), Esteban Salvatore (1), Fabiana Rossi (2), Mario Rossi (2), Judith Yanowitz (3), Daniel Hochbaum (1)
(1) Departamento de Biodiversidad y Biología Experimental. FCEN. Universidad de Buenos Aires. CABA, Argentina, (2) IBioBA-Conicet. CABA, Argentina, (3) Department of Obtestrics, Gynecology & Reproductive Sciences. Uniersity of Pittsburgh, PA. USA.

Abstract: In harsh environments, the nematode *C. elegans* develops into a dauer larva, a stress-resistant, metabolically altered and long-lived variant of the L2-stage larva. The nuclear hormone receptor DAF-12 plays important roles in development and aging and is required for dauer formation. We identified DAF-12 target genes by chromatin immunoprecipitation. To address the relevance of these genes, we conducted an RNAi screen for dauer suppressors. Inhibition of *chd-7* (chromodomain helicase DNA-binding protein) leads to developmentally arrested, abnormal dauers that are sensitive to SDS and have impaired fat accumulation. Notably, the allele *chd-7(gk290)* forms abnormal dauers with these same features, validating our screen. Longevity of *daf-2(e1370)* and *glp-1(e2144)* mutants is significantly impaired by *chd-7(gk290)* and *chd-7* overexpression increases lifespan. Loss of *chd-7* function resembled mutations in autophagy genes allowing us to uncover roles for *chd-7* and its mammalian ortholog in this process. Specifically, both *chd-7(gk290)* worms expressing the autophagy sensor GFP::LGG-1 and electron micrographs of *daf-2(e1370);chd-7(gk290)* mutants display abnormal autophagosome accumulation. Hela cells expressing the related autophagy sensor GFP-LC3 also show abnormal autophagosomes upon Chd7 knockdown, suggesting a conserved role for Chd7 in autophagy regulation. Based on structural and sequence conservation, CHD-7 shares more that 60% homology with human CHD7 and CHD8, which are related with a spectrum of human disease phenotypes. Mutations in Chd7 are associated with CHARGE syndrome, a neurodevelopmental disorder with no known treatment and disruptive mutations in Chd8 have been related with autism spectrum disorders (ASDs). Our ability to exploit *C. elegans* to analyze *chd-7* in the context of dauer formation creates an opportunity to identify relevant pathways misregulated by this class of evolutionarily conserved chromatin modifiers.

Keywords: Caenorhabditis elegans, *chd-7*, autophagy, dauer, longevity.

(1619) **FOCAL CALCIUM RELEASE DURING ACUTE UNFOLDED PROTEIN RESPONSE**

The Endoplasmic Reticulum (ER) is a multi-functional organelle that plays a critical role in a variety of processes, where the ER Ca^{2+} acts as a key messenger. Under resting conditions, the luminal Ca^{2+} concentration reflects a balance between active uptake by Ca^{2+}-ATPases and passive efflux pathways of which the translocon can play a prominent role). The translocon is an aqueous pore, primarily formed by the Sec61α core spanning the ER lipid bilayer,that is blocked by the ribosome on the cytosolic side and by the ER chaperone, BiP, on the luminal side. We hypothesize that during the acute phase of the UPR (Unfolded Protein Response), immediately after accumulation of unfolded protein in the lumen, the Ca^{2+} ER eflux through the translocon is increased. To test this mechanism of action, we performed cytosolic Ca^{2+} measurements in primary cultures of human astrocytes, expressing the Ca^{2+} indicator GCaMP6 tethered to the ER membrane, after induction of the UPR by Tunicamycin (Tm, glycosylation inhibitor). We observed focal release of Ca^{2+} (microdomains) in stressed astrocytes that was significantly inhibited by translocon blockers (emetine or anisomycin). In addition, the Tm-induced Ca^{2+} signal was amplified by pre-treatment either with AB5 cytotoxine, which specifically hydrolyses BiP, or with the translocon opener puromycin. The effect of these pharmacological tools was corroborated by co-immunoprecipitations that showed changes in the interactions either between Sec61α and BiP or Sec61α and the ribosomal protein S6. Important to note that the likehood of obtained Tm-induce local Ca^{2+} events, increase by using either the slow chelator EGTA-AM or Xestospongin C and Ryanodine ($InsP_3$ and Ry Receptors inhibitors, respectively). Taken together, these data, strongly suggest that the chaperone BiP and the ribosome are dissociated from the translocon increasing Ca^{2+} permeability.

(1638) **INDUCTION OF AUTOPHAGY PROMOTES CRUZIPAIN PROCESSING DURING *Trypanosoma cruzi* DIFFERENTIATION.**

Antonella Losinno, Patricia Romano
IHEM-CONICET

T. cruzi is the causative agent of Chagas' disease. During its life cycle, this parasite present four developmental stages: epimastigotes (epi), metacyclic trypomastigotes (MT), bloodstream trypomastigotes and amastigotes. Reservosomes are organelles of epi that accumulate proteins and lipids ingested by endocytosis. This content is digested by hydrolases to supply energy during the differentiation of epi to MT (metacyclogenesis). The autophagic pathway of *T. cruzi* is activated during starvation and differentiation. Cruzipain (Cz) is the major cysteine protease of *T. cruzi* and a key enzyme for nutrition, differentiation and host cell infection. Cz is synthesized as a zymogen, processed and delivered to reservosomes. The aim of this work was to evaluate the participation of autophagy in the distribution and function of Cz during metacyclogenesis. Epimastigotes (Y strain) were kept in BHT medium (control) or subjected to nutritional stress under TAU medium for 2 h followed by dilution in TAU3AAG medium for 72 h. By confocal microscopy, we observed that starvation induces the accumulation of Cz in compartments located at the posterior region of the parasite. Colocalization of these compartments with Atg8 and DQ-BSA (**autophagic and hydrolyt-**

ic markers respectively) increased by nutritional stress. Western blot analysis showed that the Cz zymogen was recognized in both control and starvation conditions (2 h), although the latter had decreased zymogen levels at 72 h. We also detected the mature form of Cz and a band corresponding to the carboxyl-terminal fragment only under starvation condition (72 h). When we used autophagy inhibitors, Cz did not accumulate in reservosomes. K777, a Cz inhibitor, induced a Cz distribution at the cell surface, avoiding their accumulation in the reservosomes and the differentiation into TM. These findings indicate that induction of autophagy by starvation triggers cruzipain activation and processing, and promotes *T. cruzi* differentiation.

(991) **THE EFFECTS OF AN EXCESS OF AMINO ACIDS ON LIFESPAN EXTENSION IN PROTOTROPHIC YEASTS**

Juan Facundo Gulías, Jenniffer Valencia-Guillén, Sebastián Aníbal Muñoz, Mariana Bermúdez-Moretti, Susana Correa-García

Departamento de Química Biológica, FCEN, UBA; IQUIBICEN, CONICET. CABA, Argentina

Lifespan extension has been a human challenge since ever. Aging is a multifactorial and complex process characterized by a progressive damage of cellular functions that inevitably leads to death. It is regulated by numerous nutrient-sensing pathways. Amino acids levels are sensed by at least two evolutionarily conserved and intersecting mechanisms: one involving Gcn2 kinase and the other involving the TORC1 kinase. Dietary interventions are effective strategies for preventing aging and diseases and many of them are linked to amino acid and protein levels and their regulation. The aim of this work was to study how an excess of amino acids affect longevity in prototrophic yeast cells and to determine which nutrient-pathways are involved. Chronological lifespan (CLS) was measured using the colony forming unit spot assay in cells grown in the absence and in the presence of all amino acids. We used wild type cells and cells deficient in the kinase Tor1 and in the transcription factor, Gcn4, a key regulator of amino acid biosynthesis and the main target of the kinase Gcn2. Longevity was affected neither by growth conditions nor by mutant genotypes assayed. When tolerance against thermal stress was analysed during the aging process, we found that cells lacking *GCN4* were less resistant to thermal stress than the other strains used and that amino acids had a protective effect; however, no differences during aging were observed when cells were subjected to oxidative stress. Also, we determined stress tolerance, autophagy and the activity of the unfolded protein response (UPR) pathway in cells at the exponential and stationary growth phases. Differences found before aging started did not explain the similar CLS behaviour observed. Altogether these results allow us to conclude that lifespan extension does not result solely from increased stress resistance, UPR or autophagy activation, supporting the idea of the complexity of the aging process.

Keywords: lifespan, yeast, amino acid

(1865) **DUPLICATION AND POSITIVE SELECTION DROVE UGGT-2 NEOFUNCTIONALIZATION IN *CAENORHABDITIS***

Olga Alejandra Castro (1,2), Diego Caraballo (1,3), Gabriela Acosta (1,2), Silvia Miranda (4,5), María Susana Rossi (1,3)

(3) CONICET- Universidad de Buenos Aires, Instituto de Fisiología, Biología Molecular y Neurociencias (IFIBYNE). (4) Universidad de Buenos Aires, Facultad de Medicina. (5) CONICET-Universidad de Buenos Aires, Inst. de Investigaciones Cardiológicas "Prof. Dr. Alberto C. Taquini" (ININCA).

UGGT (UDP-Glc::glycoprotein glucosyltransferase) discriminate folded from misfolded glycoproteins, is the key component of the quality control mechanism of glycoprotein folding that ensures that only properly folded proteins exit the ER. In vertebrates and in the nematode genus *Caenorhabditis* there are two homologous genes encoding UGGT-like proteins. Expression of both *Caenorhabditis* genes in *S. pombe* mutants devoid of UGGT activity showed that UGGT-1 is active while UGGT-2 although being an essential protein in worms apparently does not display a canonical UGGT activity. The aim of this study was to explore the origin and evolution of both *Caenorhabditis* UGGTs. Bayesian phylogenetic analyses were carried out in 189 UGGT sequences representing all major eukaryotic groups. The *Caenorhabditis* and the vertebrate clades are reciprocally monophyletic, and both split into two identical subtrees, revealing that UGGT went through independent duplications in these two lineages. Conservation and selection analyses were performed within the *Caenorhabditis* clade applying codon-based and lineage-based approaches analyzing the two protein domains separately, reflecting a generalized background of purifying selection in both UGGTs, suggesting that the two gene copies have been subjected to functional constrains. The catalytic domain is highly conserved as a consequence of a strong negative selective pressure, and shows almost no evidences of positive selection. In contrast, the recognition domain has undergone a positive diversifying selection process, wich showed evidences of Episodic Diversifying Selection in UGGT 2. A probable outcome of the observed selective scenario is that UGGT 1 retained the canonical function, while UGGT 2 may have retained only the catalytic domain and consequently may recognize a different substrate. In this sense, UGGT 2 would have experienced a neofunctionalization driven by diversifying (positive) selection.

(578) **LEUKEMIA: INTRACELLULAR CHANGES IN LRP-1 RECEPTOR TRAFFIC AND AUTOPHAGIC RESPONSE.**

Rubén Adrián Grosso (1), María Cecilia Sánchez (2), Gustavo Alberto Chiabrando (2), María Isabel Colombo (1), Claudio Marcelo Fader (1)
(1) Instituto de Histología y Embriología - Facultad de Ciencias Médicas, Universidad Nacional de Cuyo – CONICET. (2) Centro de Investigaciones en Biquímica Clínica e Inmunología - Facultad de Ciencias Químicas Universidad Nacional de Córdoba – CONICET.

Modification of cell membrane proteins is an important event during erythropoiesis. Under maturation stimulus, erythoid cells active intracellular process such as, nuclear extrusion, autophagy of non-necessary organelles and regulating membrane protein. In leukemia cells this maturation response is impaired. Low density lipoprotein related-receptor protein-1 (LRP1) is a transmembrane receptor involved in numerous mechanism of cancer cells like migration, survival and apoptosis regulation. We recently demonstrated that hemin (a maturation inductor) can stimulate erythroleukemia cells and activate autophagy and elimination of mitochondria. LRP1 is responsible of hemin cellular uptake. The aim of our work is to study whether hemin is able to stimulate LRP-1 traffic and by this regulate important intracellular changes in chronic leukemia cells through LRP1 signal. For this we performed an intracellular localization of LRP1 by immunofluorescence of K562 leukemia cell line. Different vesicles of endocytic and autophagic pathway were tagged with specific proteins such as Rab5, Rab7, Rab11, CD63, lysosomes and autophagosomes. Also a Golgi marker was used. We evaluate both early and late times. Moreover we study if hemin stimulates autophagy though LRP1 by western blot using silencing RNA against them and measuring levels of LC3-II protein (specific for autophagy). Importantly our results showed that hemin significantly modifies LRP1 normal intracellular localization from early endosomes and recycling vesicles to late endosomes and lysosomes in a time dependent manner. Likewise LRP1 is associated to autophagic vesicles under hemin incubation and its silencing downregulate over 50% the autophagic response. Taken together this results led us to think that hemin could regulate LRP1 activity and that this receptor is involved in crucial process as autophagy in leukemia cells. LRP1 modification may be important in cancer malignancy prognosis and therapeutics advances.

Key words: LRP1, leukemia, autophagy, cancer.

(990) **THE ROLE OF RAB24 IN AUTOPHAGY**

Emiliano Germ Gomez, Celina Amaya, María Isabel Colombo
IHEM, CONICET, FCM, UNCuyo, Mendoza Argentina

Autophagy is a highly-conserved eukaryotic degradation pathway in which cytoplasmic materials, such as molecules and organelles, are sequestered by autophagosomes and transported to the lysosome for digestion. The autophagic pathway maintains the cells' basal homeostasis and supports adaptation during stress; thus, deregulation of this process contributes to several human diseases, including cancer, bacterial or viral infections, and neurodegeneration. It is therefore critical that autophagy is properly regulated. This process requires the Rab GTPases for accurate membrane trafficking, since they control vesicle budding, targeting and fusion. Our laboratory has already shown that Rab24 participates in central vesicle trafficking events like endosome degradation and autophagy. Besides the fact that Rab24 is essential for the endosome-lysosome fusion process, little is known about the role and molecular mechanism of Rab24 in autophagy. Consequently, in the present study, we explore, in cellular models, the participation of Rab24 in autophagosome formation and maturation. For this purpose, we performed several techniques, such as protein transfections and RNAi knockdown, Western blot-based assays to monitor LC3 lipidation, and fluorescence microscopy-based methods to study the distribution of autophagosomal protein markers and molecular tandem probes. Overall, our findings reveal that Rab24 is a novel regulator of autophagy and elucidate significant insights about the role of Rab24 in specific stages of this process.

Keywords: autophagy, vesicle trafficking, Rab GTPases, Rab24.

(1525) **CHARACTERIZATION OF MICRORNAS IN *Neospora caninum* ISOLATES WITH DIFFERENTIAL PHENOTYPE BY QUANTITATIVE REALTIME PCR.**

Ludmila Sol Lopez Arias (1), Lucia Maria Campero (2), Andrea Dellarupe (2), Magdalena Rambeaud (2), Cecilia Venturini (2), Marisa Farber (1), Silvina Wilkowsky (1)
(1) Instituto de Biotecnología, Centro de Investigaciones en Ciencias Veterinarias y Agronómicas, INTA. (2) Laboratorio de Inmunoparasitología, Facultad de Ciencias Veterinarias, Universidad Nacional de La Plata.

Neospora caninum, a major cause of abortion in cattle, is an obligate intracellular parasite phylogenetically related to *Toxoplasma gondii*. A wide range of *N. caninum* isolates with specific host preferences and differential virulence has been characterized. Small non-coding RNAs play an important role in parasites, as regulatory molecules associated with physiology, infection and manipulation of immune response. Previous studies in *T. gondii* revealed the existence of a large repertoire of miRNAs, some of which were associated with virulent strains. In this regard, our aim was to explore the presence of miRNAs in *N. caninum* and the potential association with different strain phenotypes.

Four families of miRNAs (miR-15, miR-40, miR-60 and miR-61) were selected from *T. gondii* transcriptomic data. For reverse-transcription reaction, miRNAs specific stem-loop primers were designed. On the other hand, RNA and cDNA were obtained from *N. caninum* tachyzoites: Nc-6 Argentina (moderate virulent isolate) and Nc-1 (highly virulent isolate). Quantitative Real-time PCR was performed using SYBR Green master mix, 4 miR-specific forward primers and a universal reverse primer from a consensus sequence within the stem-loop.

The results showed that all the selected miRNAs were expressed in both *N caninum* isolates. Particularly, differential expression was detected for miR-15 and miR-60, being highly transcribed in the less virulent isolate (Nc-6 Argentina). On the contrary, the higher expression of miR-60 has been previously associated with increased virulence in *T. gondii* isolates.

To our knowledge, our work is the first description of miRNAs in *N. caninum* isolates. Additionally, we demonstrated the differential expression of two of the targeted miRNAs in the phenotypically diverse isolates. These results represent a promising starting point for further research on the study of regulatory role of non-coding RNAs in *N. caninum* virulence strategies.

Keywords: *Neospora caninum*, microRNAs, RTqPCR.

(1469) **CODON USAGE IN THREE SPECIES OF THE GENUS *Echinococcus.***

Lucas Luciano Maldonado, Laura Kamenetzky, Mara Rosenzvit
IMPaM - UBA – CONICET.

Species of the genus *Echinococcus* are Platyhelminthes parasites causatives of hydatid diseases in animals and humans all over the world. They have complex life cycles which comprise an intermediated and a definitive host, and such hosts infections specificity or preference seems to depend on the *Echinococcus* species.

The codon usage bias is the non-random usage of synonymous codons for coding amino acids. The synonymous sites are under weak selection, and codon usage bias is kept by the equilibrium in mutational bias, genetic drift and selection pressure. The differential codon usage choices are also relevant to human infecting by many pathogens organisms.

Previously we have sequenced and annotated the genomes of three *Echinococcus* species which have allowed to perform several analyses such as orthology studies, genetic variability and microRNA/target genes repertory. Here we performed codon usage analyses using a whole genome datasets for comparative genome analysis of *E. canadensis*, *E. multilocularis* and *E. granulosus* by applying codonW, CodonO softwares and principal component analysis (PCA) on 3000-4000 genes and we evaluated the nucleotide content in each position of the codons.

As demonstrated by PCA and Enc analyses many genes have non-random selection of codon for coding proteins. Indeed genes with strong codon bias seem to be expressed at a higher level compared to other genes. However most of the genes appear not to have a biased codon usage and the frequencies of codons among the *Echinococcus* species are similar and exhibit a strong RSCU correlation among each other. On the other hand the use of UAG as a stop codon signal is absent for all the genes, otherwise the stop codons UAA and UGA comprises the 46.4% and 53.6% of termination signal respectively.

Comparative analysis of codon usage among the *Ehinococcus* species could reveal genes responsible for specie-specific phonotypes and host preference infections.

Keywords: *Echinococcus,* codon usage, genes

(1799) **DEVELOPMENT OF SIMPLIFIED INDUCIBLE EXPRESSION SYSTEMS FOR TRYPANOSOMATIDS.**

Gabriela Niemirowicz, Juan José Cazzulo, Vanina Eder Alvarez, León Alberto Bouvier
Instituto de Investigaciones Biotecnológicas Dr. Rodolfo A. Ugalde - Instituto Tecnológico de Chascomús (IIB-INTECH). Universidad Nacional de San Martín (UNSAM). Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET).

In trypanosomatids, inducible expression systems are based on the sequential use of two types of genetic manipulation vectors. First, wild type strains have to be transfected with plasmids that code for regulatory elements such as bacterial repressors and polymerases. It is only after establishing these cell lines that is possible to modulate the expression of sequences of interest carried in the second type of plasmid that make up the system. In addition, since the discovery of highly processive RNA transcription of bacteriophage polymerases in *T. brucei*, these enzymes have been included in almost all inducible expression systems developed so far, although endogenous promoters that allow constitutive as well as regulatable expression have been described.

In this work we conceived a simplified inducible expression system based entirely on endogenous promoters with operators for bacterial repressors. It is worth noting that along with reporter genes and selectable markers the latter represent the only included foreign elements. This reduced set, made possible to accommodate the entire system together with the sequence of interest in a single vector and

thus, the obtention of an inducible cell line can be accomplished by one step transfection of a wild type strain.

Due to the fact that *T. brucei* is more amenable to genetic manipulation, initial prototypes were designed for this organism and transfected in procyclic Lister-427 trypomastigotes. After selection, Western blot analysis revealed a 35-fold expression induction of the reported GFP gene compared to non-induced cells.

The system described here will represent a useful molecular genetic tool that, independently of the strain background, will enable tightly-regulated protein expression and stem-loop based RNAi strategies. Once established, it will constitute the starting point for the development of equivalent systems for other trypanosomatids.

Keywords: genetic manipulation, inducible expression, trypanosomatids.

(1672) **THE HYPERVARIABLE REGIONS OF kDNA MINICIRCLES IN THE 6 MAIN LINEAGES OF *Trypanosoma cruzi*: A NEXT GENERATION SEQUENCING APPROACH**

Fanny Rusman (1), Nicolás Tomasini (1), Noelia Floridia Yapur (2), Paula Gabriela Ragone (1), Patricio Diosque (1)
(1) Instituto de Patología Experimental. (2) Cátedra de Química Biológica, Facultad de Ciencias Naturales, Universidad Nacional de Salta.

The kinetoplastic DNA of *Trypanosoma cruzi* consists of dozens of maxicicles (analogous to the mitochondrial DNA of other eukaryotes) and about 30,000 minicircles. Each minicircle (≈ 1.4 kb) is organized into four conserved regions (≈ 120 bp) located 90° apart and intercalated by an equal number of hypervariable regions (≈ 240 bp) known as mHVR (minicircle hypervariable regions). There are few known mHVR sequences, possibly due to technical difficulties for sequencing this kind of DNA regions in the past. Nowadays, the Next Generation Sequencing (NGS) techniques open the possibility of a deeper knowledge of the mHVR sequence diversity. In the present work, we describe our general approach for the study of the diversity of mHVR sequences in the main 6 DTUs of *T. cruzi*, the generation of libraries of these regions and the sequence diversity obtained by NGS. These are the first results in the framework of a broader work that aims to study the diversity of mHVRs and their evolution, as well as the searching for lineage specific sequences in order to be used in genetic typing.

Keywords: *T. cruzi,* DTUs, mHVR, NGS.

(233) ***TRYPANOSOMA CRUZI* LONG READS BASED ASSEMBLY: REVEALING THE REAL EXTENT OF GENOME COMPLEXITY**

Luisa Berná, Matías Rodriguez (1), Maria Laura Chiribao (2), Adriana Parodi (3), Gastón Rijo (2), Fernando Alvarez-Valin (1), Carlos Robello (2)
(1) Sección Biomatemática, Unidad de Genómica Evolutiva, Facultad de Ciencias, Universidad de la República, Montevideo, Uruguay. (2) Unidad de Biología Molecular, Institut Pasteur de Montevideo, Montevideo, Uruguay. (3) Sección Genética, Facultad de Ciencias, Universidad de la República, Montevideo, Uruguay.

Although the genome of the *Trypanosoma cruzi* (CL Brener strain) is available since 2005, and those from some additional strains were later reported, very high-quality genomic sequences are not yet available due to the intrinsic genome complexity of this parasite. This limitation poses a number complications for diverse types of analyses that require high degree of precision. Third-generation sequencing technologies are particularly suitable to address the challenges associated with the high degree of repetition of *T. cruzi*̂s genome since they allow obtaining sequencing reads of 15 kb in length and many larger than 30 kb. This opens the possibility to directly determine the full sequence of large clusters of repetitive sequences (without collapsing them), as well as determining the single copy sequences that surround both sides of these clusters. As a consequence assembly fragmentation is largely avoided. Furthermore this approach allows separated assembly of homologous chromosomes, namely haplotypes are retrieved as separate contigs/scaffolds instead of a unique mosaic sequence. We present the genome of the hybrid *T. cruzi* strain TCC, sequenced using PacBio SMRT technology. Its final assembly consists in a diploid genome of 86.7Mb, the 9% of which being composed by a well known satellite of 195pb. The remaining genomic regions are distributed in only 692 contigs with an N50 of 300Kb, the longer ones being larger than 1 MB and correspond to entire chromosomes. New tandem and disperse repetitive sequences were identified, including some located inside coding sequences. A total of 30947 genes were identified, 62% having an assigned function. The quality of this new *T. cruzi* genome allows one to separate the two parent halpotypes as well as to identify the centromeres, the real extension of repetitive elements and genes.

(1599) **CRISPR-CAS9 TARGET VALIDATION OF *Trypanosoma cruzi* BROMODOMAINS**

Alejandro Pezza (1), Teresa Cruz Bustos (2), Victoria Alonso (1), Luis Tavernelli (1), Roberto Docampo (2), Esteban Serra (1)
(1) IBR-CONICET. (2) ctegd-UGA.

Trypanosoma cruzi is a protozoan parasite and the causative agent of Chagas´ disease. This parasite has a complex life cycle with two intermediate hosts, a triatomine insect and a mammalian vertebrate. Nuclear gene organization in *T. cruzi* is atypical from other eukaryotic cells. Genes arrange in long tandems that are transcribed polycistronically from a small number of initiation sites. The transcription is driven by a limited number of basal nuclear factors and its regulation depends on chromatin structure. Among the usual proteins that participate in epigenetic regulation, a small number of genes coding for acetylases, deacetylases and bromodomains are present in the *T. cruzi* genome. Bromodomains are conserved protein modules capable of binding acetylated lysines and found in many proteins associated with chromatin. *T. cruzi* has at least six genes that encode for bromodomain-containing factors (TcBDF1-6). The overall objective of the project is to explore bromodomains as drug target in *T. cruzi*, by assaying their essentiality using a CRISPR/Cas9 gene deletion approach. Briefly, target sequences (SgRNA) were cloned into the expression plasmid pTREX-Cas9-neo. Parasites were transfected by electroporation and drug selected. Deletion of the target genes were determined by PCR. We obtained mutated parasites for all the genes tested but only for Bdfx we got the homozygous population, which mean that this gene is not essential for epimastigotes growth. For the rest of the genes we detected less amount of protein for mutated cultures but we couldn´t get homozygous null mutants, and only one of them showed a detrimental growth rate. We are evaluating the essentiality of these genes in the other life cycle stages as well as testing the expression of dominant-negative mutants approach for some of the genes. Altogether these results suggest that except Bdfx, bromodomains genes could be crucial for *T. cruzi* normal growth.

(1828) **IDENTIFICATION OF A RARE DORMANT SUB-POPULATION OF *TRYPANOSOMA CRUZI* AMASTIGOTES ABLE TO REASSUME PROLIFERATION, INFECTION AND GENERATION OF NEW QUIESCENT FORMS**

Fernando Valdez, Angel Padilla, Rick Tarleton
Center for Tropical and Emerging Global Diseases, University of Georgia, Athens, Georgia, USA.

Benznidazole (BZ), the primary drug used to treat Chagas disease, fails to provide parasitological cure in the majority of cases, despite long treatment times (up to 60 days). In a number of infections, drug treatment failures have been linked to the presence of subpopulations of pathogens that become physiologically inactive or dormant. These so-called persister cells may be stochastically generated in pathogen populations and have been hypothesized to serve as a survival mechanism against possible catastrophic events that could eliminate an entire metabolically active population. In our

analysis of persisting parasites in mice with chronic *T. cruzi* infection, we consistently observed the existence of rare amastigotes not undergoing active proliferation, as assessed by the incorporation of the thymidine analog 5-ethynyl-2´-deoxyuridine (EdU) into amastigote DNA. Quiescent amastigotes were also evident *in vitro* even after prolonged incubation with EdU (72hr). TUNEL assays determine that these dormant parasites were not dead within host cells. Incorporation of EdU into DNA can impact DNA replication, so we used labeling with fluorescent dyes as an alternative protocol to monitor amastigote replication. We not only confirmed *in vivo* and *in vitro* results, but also found that non-proliferating amastigotes were able to resume proliferation: differentiate to trypomastigotes, infect new host cells, replicate and generate again a progeny of dormant forms. Remarkably, the screening of adipose tissue from infected mice treated with BZ revealed the resistance capacity of dormant parasites. Replicating amastigotes are sensitive to drug and could not been detected. The cause of this arrest and the link between these parasites and drug treatment failures *in vivo* will be the subject of future studies.

Keywords: Trypanosome; dormancy; quiescence; proliferation; amastigotes.

(1902) **NUCLEAR ARCHITECTURE AN CHROMOSOMOC INTERACTIONS IN T.CRUZI**

Martin Ciganda (1), Beatriz Garat (1), José Roberto Sotelo (2), Pablo Smircich (2)
(1) Facultad de Ciencias, Universidad de la República, Montevideo, Uruguay. (2) Instituto de Investigaciones Biológicas Clemente Estable, Montevideo Uruguay.

Trypanosoma cruzi es un parásito protozoario responsable de la enfermedad de Chagas en las Américas, desde el sur de Estados Unidos hasta el cono sur Sudamericano. La enfermedad afecta con más dureza las zonas rurales y pobres, donde el insecto vector hematófago aparece asociado a viviendas precarias. La transmisión ocurre principalmente a través de insectos de la familia *Reduvidiae*, de forma congénita de madres portadoras y por tranfusiones sanguíneas y trasplantes de órganos o tejidos. La enfermedad crónica tiene a menudo como manifestación la miocarditis chagásica, que es la forma de falla cardíaca de origen infeccioso más común a nivel global. En tripanosomátidos se considera que el principal mecanismo de control de la expresión génica es post- transcripcional. No se han identificado secuencias promotoras de la ARN pol II (con la excepción del promotor del gen del spliced leader o SL). El genoma de *T. cruzi* (de 60.3 Mb) consiste en 41 cromosomas (con hasta 50% de secuencias repetidas) en los que los genes se organizan en clusters de transcripción policistrónicos. A diferencia de los policistrones procariotas, éstos contienen genes no necesariamente relacionados funcionalmente. Estas unidades transcripcionales pueden estar presentes en una u otra hebra y la transcripción tiene lugar de forma bidireccional entre dos clusters divergentes adyacentes. Las regiones de cambio de hebra codificante se denominan SSR (Strand Switch Regions). Los mRNA se generan a partir del procesamiento de los transcritos policistrónicos mediante trans-splicing y poliadenilación. Nuestra hipótesis es que la regulación génica en *T. cruzi* involucra, entre otros, aspectos epigenéticos a nivel de la conformación de la cromatina. Es razonable predecir que exista una arquitectura nuclear dinámica en *T. cruzi* que incluya interacciones a distancia de las

SSR entre sí y/o con otros elementos reguladores. Para definir las regiones de interacción genómica con SSRs, estamos utilizando como aproximación técnica la captura de conformación de la cromatina (C4). Las SSRs pueden ser bidireccionales divergentes, bidireccionales convergentes, o unidireccionales. Para sistematizar nuestro análisis, seleccionamos una SSR correspondiente a cada categoría. Generamos moléculas circulares cerradas de ADN conteniendo las regiones interactuantes correspondientes a cada una de las regiones *bait* seleccionadas. Valiéndonos de una base de datos con las regiones de cambio de hebra de *T. cruz*i construida previamente, diseñamos oligonucleótidos específicos para las regiones *bait*, y amplificamos los productos interactuantes para cada categoría. Los productos están siendo analizados por secuenciación masiva.

(309) **MOLECULAR DISSECTION OF THE APICOMPLEXA CENTROSOME; A SMALL ORGANELLE WITH BIG POTENTIAL**

Maria Eugenia Francia
Instituto Pasteur de Montevideo.

The centrosome is a key organelle orchestrating many cellular processes. It is involved in coordinating chromosome segregation, intracellular vesicle trafficking, signaling cascades, and the assembly of the cortical cytoskeleton and of the basal body and its associated flagella. In previous work we demonstrated that the centrosome in Apicomplexan parasites, a phylum which encompasses several human and veterinary pathogens, is responsible for coordinating the progression of the division cycle through the assembly of multiple cell-cycle specific physical tethers. These tethers ensure that nuclear mitosis and cytokinesis occur synchronously; their individual ablation leads to futile division cycles, and parasite death. In addition we, and others, have shown that the structure and organization of the ApiCentrosome is unique and divergent. Moreover, the ApiGenomes do not appear to encode for the canonical regulators of centrosome biogenesis found in the mammalian hosts. Thus, we propose that the ApiCentrosomes constitute a relatively unexplored rich source of potentially drugabble targets. Here, we set out to explore the molecular composition of the ApiCentrosome by identifying its proteome, and the interactomes of previously identified centrosome components in the model Apicomplexa *Toxoplasma gondii*. Our results will shed light onto the biology of a critical organelle for parasite survival, and will broaden our knowledge on the molecular composition and evolutionary history of this important organelle.

(1934) **MDR1 POLYMORPHISMS IN HIV INFECTED INDIVIDUALS. ITS INFLUENCE IN PORPHYRIA CUTANEA TARDA TRIGGERING**

Ana Maria Buzaleh (1,2), P. Pagnotta (1), J. Zuccoli (2), V. Parera (2), M.v. Rossetti (2), J. Lavandera (3), A. Batlle (2), V. Melito (1,2)

(3) Cátedra de Bromatología y Nutrición, Facultad de Bioquímica y Ciencias Biológicas, Universidad Nacional del Litoral, Santa Fe, Argentina.

A high association of Porphyria Cutanea Tarda (PCT) with HIV infection (17%) is found in our country. To date slight evidence exists about if triggering factors of PCT, a rare toxicogenetic disease, in HIV patients are related to the infection and/or therapy. The Multidrug Resistance protein (MDR1) is involved in the transport of xenobiotics and antiretroviral drugs. Some polymorphisms in MDR1 gene are of clinical importance, among them: exon 12 (c.1236C>T), 21 (c.2677G>T/A) and 26 (c.3435C>T) with high incidence in Caucasians. The frequency of these SNPs was previously studied in control, PCT and PCT-HIV individuals. The aim was to complete this research analyzing HIV patients without PCT by PCR-RFLP assay. The analysis of 1236T-2677T/A-3435T haplotypes was performed. The polymorphic allelic frequencies were 0.45 (exon 26), 0.36 (exon 12) and 0.37 (exon 21). Genotypic frequencies were as follows: exon 26: CC 25.0%, CT: 59.4%, TT 15.6%; exon 12: CC 28.1%, CT 71.9%, TT 0%; exon 21: GG 40.0%, GT 43.3%, TT 13.3%. In HIV population, the frequency of T allele for exon 26 was lower than PCT and PCT-VIH groups, although differences were not significant. For exon 21, T allele frequency was significantly minor ($p<0.05$) in HIV than PCT-HIV group. For exon 12, the mutant allele in HIV group had a less frequency ($p<0.05$) respect to PCT cohort. The genotypic analysis showed that the allele T of exon 26 and 21 is presented in homocigosis with a minor frequency than PCT-HIV group; the same observation was found for exons 26 and 12 in HIV cohort but in comparison with PCT group. Our previous results showed the same conclusions suggesting that the polymorphism of exon 21 could be involved in the manifestation of PCT in HIV individuals related to the antiretroviral therapy used in these patients; while in exon 12, T allele could be associated with other risk factors in the onset of PCT.

INATA 3 / IMMUNOLOGY (INNATE IMMUNITY) 3

(111) EXPRESSION, INTRACELLULAR LOCALIZATION AND PTMS IN DIFFERENT CELL LINES OF THE MRNA DECAY REGULATORS OF THE ZFP36 FAMILY

Cristian Jorge Alejandro Asensio
Biomed CONICET UCA

Abstract: 3 nucleo-cytoplasmic shuttling, mRNA binding, CCCH zinc finger, PPPP containing, low-abundant phosphoproteins (zfp36, zfp36L1, zfp36L2) compose the zfp36 family. In the cytosol trough 2 central tandem zinc fingers, they bind to AU-rich elements (ARE) in the mRNA´s 3'UTR resulting in mRNA instability/ degradation by other proteins. Several ARE-containing mRNAs, especially of inflammatory mediators, are stabilised by the p38 pathway through inactivating phosphosites in these proteins. To understand the elusive particular role(s) of the L1 member, different cell lines were studied assessing their expression by WB and qPCR. Several antibodies were tested. Zfp36 protein was detected for the first time in HeLa by an improved WB and IP. L1 and L2 were KD in HeLa by RNAi. The effects on p38-regulated inflammatory mediator expression were examined. L1 function was investigated in L1 -/- cell lines (n=17). L1 or L2 did not contribute to post-transcriptional regulation of inflammatory mediators by the p38 pathway in HeLa or L1 null cells. L1 null cells over-expressed IL-6 protein/mRNA but L1 was not regulating IL-6 mRNA stability. Instead, IL-6 underwent fastest transcription in the L1´s absence suggesting that the IL-6 transcript is an indirect target through some factor being itself a L1 target. On the other hand, L1 and Zfp36 showed reproducible ($p \leq 0.01$, n=19) inverse basal protein expression levels in macrophages, with L1 increasing and Zfp36 decreasing during differentiation, suggesting that L1 has actually a role in sustaining a Mc-MΦ differentiation switch. Concerning PTMs, the phosphorylation extent was regulating the intra-cytosolic localization with hyperphosphorylated forms of Zfp36 and L1 becoming insoluble in the cytosol and putatively associated with the cytoskeleton. Other results suggest roles for Pro isomerisation and for electrostatic interactions in the fine-tuning, rheostatic regulation of the activity, level and localization of these proteins.
Keywords: mRNA

(169) GLYCAN RESIDUES ARE INVOLVED IN THE RECOGNITION AND IMMUNOGENICITY OF S-LAYER GLYCOPROTEIN FROM *Lactobacillus kefiri*

Mariano Malamud (1), Paula Carasi (1), Teresa Freire (2), María De Los Angeles Serradell (1)
(1) Cátedra de Microbiología, FCE, UNLP, La Plata, Argentina. (2) Laboratorio de Inmunomodulación y Desarrollo de Vacunas, Departamento de Inmunobiología, Facultad de Medicina, UdelaR, Montevideo, Uruguay.

Surface layers are (glyco)-proteinaceous cell envelopes ubiquitously found in different bacterial species, including potentially probiotic *Lactobacillus kefiri*. In previous studies, we showed that S-layer glycoprotein from *L. kefiri* CIDCA 8348 (SLP-8348) was not able to induce the activation of macrophages by itself, but it favored the LPS-induced response, since there was a significant increase in the expression of co-stimulatory molecules, IL-6 and IL-10 in comparison with LPS-stimulated cells. In this study, we aim to investigate the role of glycan residues in SLP-8348 internalization by murine macrophages as well as in its immunogenicity. SLP-8348 was removed with 5 M LiCl and exhaustively dialyzed against PBS. Atto-647N-labeled SLP-8348 was incubated with RAW 264.7 macrophages both at 4°C (to evaluate binding) and at 37°C (to evaluate internalization), and fluorescence intensity was measured by flow cytometry. RAW 264.7 cells internalized the SLP-8348 in a process that was mediated by carbohydrate-receptor interactions since it was inhibited by glucose, mannose or EGTA, a Ca+2 chelating agent. These results correlated with the recognition of SLP-8348 by ConA. Moreover, EGTA completely abrogated the effect of SLP-8348 on LPS-stimulated RAW 264.7 cells. To test the SLP-8348 immunogenicity, one dose (10 μg/mouse) of SLP-8348 or oxidized SLP-8348 (SLPOx-8348) in combination with incomplete Freund´s adjuvant was subcutaneously injected into the right flank in front of the hind leg on BALB/c mice. After ten days, cells from inguinal lymph nodes were labeled with CFSE and stimulated *in vitro* with SLP-8348 (10 μg/ml) for five days. Proliferation index of $CD4^+$ T cells as well as secretion of IFN-γ were significantly lower in the group of mice treated with SLPOx-8348 respect to SLP-8348-treated mice. This is the first report showing that glycan chains are involved in the uptake of a SLP by macrophages and are crucial in the immunogenicity of this glycoprotein.

(527) DEVELOPMENT OF INNATE T CELLS IN THE THYMUS UNDER INFECTIOUS/INFLAMMATORY SYSTEMIC CONDITIONS

Natalia Baez, Constanza Savid Frontera, Fabio Cerbán, Ximena Volpini, Cristina Motrán, María Cecilia Rodríguez Galán
Departamento de Bioquímica Clínica, Facultad de Ciencias Químicas, UNC. CIBICI-CONICET.

Our previous work demonstrated that during the acute stage of certain infections with a strong Th1 component (*Trypanosoma cruzi* or *Candida albicans*), SP CD8 thymocytes alter their differentiation from "conventional" to "innate" lineage. Innate $CD8^+$ cells express a particular phenotype ($CD44^{hi}$ $CD122^{hi}$ $EOMES^{hi}$), produce high levels of IFNγ and have high cytotoxic activity. The switch in the SP CD8 lineage occurs by the inflammatory process since we obtained similar data when we induced systemic expression of IL-12 and IL-18 by hydrodynamic injection of their cDNAs. The aim of our work is to determinate the stage at which innate $CD8^+$ T cells develop in the thymus and the molecular mechanisms that are involved in this differentiation. Our data demonstrate that the innate phenotype give rise as early as the double positive (DP) stage since when we co-cultured DP or SP CD8 $CD45.1^+$ control thymocytes with $CD45.2^+$ *T. cruzi*-infected thymocytes we observed that $CD45.1^+$ cells adopt the mentioned innate features ($p<0,05$).

The canonical Wnt/β-catenin signaling pathway is involved both in the differentiation of CD8 T cells and the generation of functional CD8 T cell memory. To investigate if this particular pathway is involved in the generation of innate $CD8^+$ cells, we co-cultured $CD45.1^+$ control thymocytes with $CD45.2^+$ control or *T. cruzi*-infected thymocytes in the presence of Lithium chloride, an inductor of canonical Wnt pathway and we observed up-regulation of CD44 and EOMES regardless of the infection ($p<0,05$), while in the presence of iCRT, an inhibitor of β-catenin signaling, $CD45.1^+$ control thymocytes down-regulate CD44 and EOMES in both control or infected conditions ($p<0,05$).

The development of innate $CD8^+$ T cells in the thymus under Th1 systemic processes may have implication in the output and the repertoire of T cells in secondary immune organs. Canonical Wnt pathway can be implicated in this deviation, but more experiments are necessary.

Keywords: Thymus; innate T cells; inflammatory/infectious processes; IL12 plus IL18; Wnt/β-catenin.

(672) EXTRACELLULAR ACIDOSIS DRIVES THE DIFFERENTIATION OF HUMAN MONOCYTES INTO DENDRITIC-LIKE CELLS

Fernando Erra Díaz, Ezequiel Dantas, Gabriel Duette, Juan Sabatté, Jorge Geffner
INBIRS- Facultad de Medicina – UBA.

Differentiation of monocytes into macrophages and dendritic cells (DCs) is likely determined by the properties of the inflammatory milieu, however, little is known about the identity of the factors that control the polarization of monocytes toward each of these fates. Extracellular acidosis is a common feature of inflammation and the tumor microenvironment. Here, we analyzed the ability of extracellular acidosis to modulate monocyte's differentiation profile. Culturing PBMCs or isolated monocytes(>85% purity) for 7 days in medium supplemented with 10% FCS adjusted to pH 6.5, in the presence of PHA (2 μg/ml) or allogeneic lymphocytes (monocyte-lymphocyte

ratio 1:4), resulted in the appearance of an adherent spindle-shaped population of cells displaying a DC-like phenotype, characterized by the expression of CD1a, CD1c, DC-sign, HLA-DR and low/undetectable CD14. This effect was not observed in cells cultured at neutral pH. Taking the expression of CD1a as a marker of DCs, we found that isolated monocytes cultured with PHA for 7 days, at pH 6.5 or 7.3, resulted in 70±10% vs 0.8±0.6% of CD1a+ cells respectively (mean±SE,n=6,p<0.001). A similar phenotype was observed for isolated monocytes cultured for 7 days at pH 6.5 in medium supplemented with 0.1% BSA, in the absence of any other stimulus: 40±10% vs 2±1% of CD1a+ cells, (pH 6.5 vs 7.3 respectively, n=15, p<0.001). These CD1a+ cells significantly (p<0.01) up-regulated the expression of HLA-DR and CD86 upon LPS stimulation, suggesting the acquisition of a DC-like mature phenotype. Moreover, they were shown to be able to stimulate the proliferation of allogeneic CD4 T cells with much more efficiency than monocyte-derived macrophages obtained by treatment with M-CSF (p<0.01), and in a similar fashion than DCs differentiated under traditional conditions (in the presence of IL-4 + GM-CSF). Our results suggest that local acidosis might be a relevant trigger of DC differentiation during the course of inflammatory processes.

(696) **DIFFERENTIAL EFFECTS OF LACTIC ACID BACTERIA PEPTIDOGLYCANS ON LUNG EPITHELIAL CELLS AND ALVEOLAR MACROPHAGES**

Yanina Kolling (1), Mariana Ferrero (2), Susana Salva (1), Pablo Baldi (2), Susana Alvarez (1)
(1) CEREA-CONICET. (2) IDEHU-UBA-CONICET.

We demonstrated that peptidoglycan from *Lactobacillus rhamnosus* CRL1505 (Pg05) is as effective as viable strain for improving systemic and respiratory humoral immune response against *Streptococcus pneumoniae* in malnourished mice. These immunomodulatory capacity cannot be extrapolated to peptidoglycans (Pgs) from other strains. The aim of this work was to study the interactions of Pgs obtained from different lactobacilli, with mice lung epithelial cells (LEC) or alveolar macrophages (AM), in order to elucidate the mechanisms involved in the differential effect of Pg05. We compared Pg05 with Pgs from the non-probiotic *L. rhamnosus* CRL534 (Pg534) and from the probiotic *L. plantarum* CRL1506 (Pg06). AM or LEC were cultured 24h or 24-48h with different concentrations of Pg05, Pg06 or Pg534, in the absence or presence of *S. pneumoniae*. In addition, we studied the cytokines production of LEC with conditioned medium from AM pre-stimulated with Pgs. The results showed that 90% of LEC and AM remained viable after the treatments with Pgs. Pg05 (50 ug/mL) and Pg06 were able to differentially modulate the cytokines production in AM and LEC. Unlike other Pgs, Pg05 significantly modulated the activation of AM by an increase of IL-1β, KC and IL-10 with a decrease of TNF-α (p<0.05). In the same way, although Pg05 and Pg06 induced an increase of IL-17 in LEC, only Pg05 was able to increase IL-10. Stimulation of LEC with AM conditioned medium showed a diferential production of cytokines between pgs, with an pro-inflammatory profile to Pg06 and Pg534, and an immunomodulatory profile to Pg05.Pam-3-cys (TLR1/TLR2 agonist) increased the effect of the Pgs, suggesting the participation of TLR2 in the interaction Pg-LEC. In conclusion, the immunomodulatory effect of Pg05 is a strain specific property and it could act inducing the activation of epithelial cells and macrophages, which could be responsible to improve the immune response against pathogens.

Key words: peptidoglycan, Lactobacilli, lung epithelial cells, alveolar macrophages.

(839) **EFFECTS OF SAGS OF THE EGC OPERON ON INNATE IMMUNE CELLS**

Sofia Noli Truant (1), Nadia Yasmín Towstyka (2), María Belen Sarratea (1), Belen Antonoglou (1), Laura Iannantuono Lopez (1), Emilio Luis Malchiodi (1), Carolina Jancic (2), Marisa Mariel Fernandez (1)
(1) Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Cátedra de Inmunología-IDEHU (UBA-CONICET), Buenos Aires, Argentina, (2) Instituto de Medicina Experimental (IMEX) CONICET - Academia Nacional de Medicina

Bacterial superantigens (SAgs) are enterotoxins that bind to MHC-II and TCR molecules, activating as much as 20% of T cells and promoting a cytokine storm which enhances endotoxic shock and produces immunosuppression, hindering the immune response against bacterial infection. The egc operon reported in autochthonous S. aureus strains includes natural variants of the SAgs genes seg, sei, sem, sen and seo. We have previously characterized the complementary activity of SEG, SEI, SEO and SEM on phagocytic cells, and reported a M1 response tendency.

In the present work, we investigate if other cells of the innate immunity are responsible for this pro inflammatory profile. Thus, we evaluated the SAgs effect on human purified γδ T cells from healthy donors by flow cytometry and ELISA. We found that, in contrast to the effect on αβ T cells, SAgs activated γδ T cells from 0.1 μM (p<0.05), but became toxic at 10 μM. We also found a significant production of IFN-γ and TNF-α since 0.1 μM (p<0.05). Such activity was not related to the αβ TCR binding site, since mutant SAg which not bind to this TCR, activated γδ T cells as much as wild type SAgs. Therefore, SAgs display a differential activity on γδ T cells, compared to αβ T cells.

Given that CD1 molecules are targets of γδ TCR we analyzed their expression on human mononuclear cells upon SAgs stimulation, by flow cytometry. We found a differential expression of monocytic CD1a and b in response to these SAgs (p<0.1).

The previously described M1 profile induced by SAgs on monocytes and macrophages and the present demonstration that SAgs stimulate γδ T cells to produce IFN-γ and TNF-α, strongly suggest an early pro inflammatory activity of SAgs on the innate immune response. In addition, the reduction of the pool of phagocytic and effector cells and the generation of a non-efficient Th1 profile would conspire against the successful eradication of an extracellular bacteria.

(941) **DECTIN-1 PATHWAY-MEDIATED IMMUNOMODULATION IN THE LOCAL RESPONSE DURING *CANDIDA ALBICANS* BRAIN INFECTION.**

Cecilia Vigezzi, Emilse Rodríguez, María Soledad Miró, Paula Alejandra Icely, Hugo Cejas, Claudia Elena Sotomayor
Fac. Cs Químicas. UNC. CIBICI-CONICET

b-glucans of the fungal wall are recognized by Dectin-1 receptor. This interaction is essential for immune response to *C.albicans* in the periphery, but little is known about its role during Central Nervous System infections. b-glucans are widely recognized as immunomodulators, and it has been proved *in vitro* that the activation of microglia through Dectin-1 attenuates the proinflammatory response. Our aim was to evaluate the role of Dectin-1 recognition in brain, during *C.albicans* systemic infection. Male C57BL/6 (WT) and Dectin-1 deficient (KO) mice were injected intravenously with *C.albicans* SC5314 ($2.5x10^6$ yeast), and at 4, 12, 24 and 48h post-infection (pi) the animals were sacrificed. The fungal burden (CFU) was studied in blood, kidney and brain homogenates. An early colonization was observed in the periphery as well as in brain(p_{4h}<0.05). Brain innate immune response was assessed at early times, in order to study the contribution of resident cells. At 4 and 12h, Dectin-1 and IL-1b expression (qPCR), *in situ* pro- and anti-inflammatory cytokines secretion (IL-1b,IL-6,TNFa,IL-10,TGFb)(ELISA), histopathological and microgliosis/astrogliosis studies were performed. The fungal burden was higher in WT than KO mice(p<0.05). Interestingly, infection in WT mice does not induce proinflammatory cytokines secretion at 4h, while a significant increase was observed in KO mice with sustained levels at 12h. Local IL-1b and TNFa secretion in KO mice was significantly higher than in WT animals at 4h(p<0.05). Moreover, the IL-1b mRNA decreased at 12h pi in WT(p<0.05) but not in KO mice. TGFb production was downregulated after the infection in WT($p_{4h,12h}$<0.05) but not modified in KO mice. When TGFb secretion between groups was compared, significant differences were observed(p<0.05).This study provides new evidences about the role of Dectin-1 in immunomodulatory mechanisms developed in the brain in order to moderate the delicate balance between inflammation and fungal control.

Keywords: *C.albicans*, Dectin-1, b-glucans.

(1287) **EFFECT OF IL-10 ON RECRUITMENT OF PMN-LIKE MYELOID CELLS (PLMCs) DURING THE ESTABLISHMENT OF BACTERIAL ENDOTOXIN-INDUCED TOLERANCE**

Marlina Olyissa Cordoba Moreno (1), Adriana Fontanals (2), Gonzalo Pineda (3), Victoria Ramos (1), Martin Isturiz (1), Barbara Rearte (1)

(1) Laboratorio de Fisiología de los Procesos Inflamatorios, IMEX-Academia Nacional de Medicina. (2) Fundación Instituto Leloir, Buenos Aires, Argentina. (3) Laboratorio de Patogénesis e Inmunología de Procesos Infecciosos, IMEX-Academia Nacional de Medicina.

In sepsis by Gram-negative, endotoxin -LPS- is capable of inducing a tolerance state to LPS (TOL), the initial step of immunosuppression, the main cause of death. We have previously demonstrated that the TOL in absence of IL10 could improve innate immune response mainly mediated by PMN recruitment. The aim of this work was to evaluate the IL-10 effect on the recruitment of PLMCs with high levels of CD11b+/GR1+ and CD11b+/Ly6G+ in TOL. For this, BALB/c wild type(WT) and IL-10 deficient(KO) mice are used. The TOL establishment is achieved with a regimen of increasing doses of LPS (0.25-10ug/mouse) for 10 days. Glucocorticoids (GC) levels are measured by RIA. Flow cytometry was applied to measure PLMCs. During the establishment of TOL an increase in the percentage of recruitment of PLMCs is shown, this increase is greater in KO: %cells-spleen: WT-TOL:10.99±1.24, KO-TOL:32.26±4.93*, *p<0.001; %cells-femur: WT-TOL:45.02±2.14, KO-TOL:73.85±4.33*, *p <0.0001 (these data correlate with the increase previously seen in blood and peritoneum). At the same time, GC levels remain elevated in TOL mainly in KO: [GC](pg/ml) day 3 (WT-TOL:1800±591, KO-TOL:9092±1654*, *p<0.05), day 7 (WT-TOL:1696±523, KO-TOL:11203±518*, *p<0.001) and day 11 (WT-TOL:1725±219, KO-TOL:9992±2492*, *p<0.0001). At the end of the TOL schedule, mice received a lethal dose of LPS(200ug/mouse) and survival was evaluated up to 48hs: % survival: WT-TOL:100%(5/5), KO-TOL:0%(0/4). Our results indicate that the IL-10 is involved in the recruitment of PLMCs into TOL and this action could be regulated by the relationship between IL-10 and GC. On the other hand, the increase of PLMCs along with the high levels of GC in the TOL in the KO mice does not seem sufficient to protect them from a LPS shock. These facts will be further developed in the future.

Keywords: Sepsis, LPS, IL-10, GC, PMN.

(1294) **DIFFERENTIAL RESPONSE OF DOPAMINE MEDIATED BY β-ADRENERGIC RECEPTORS IN HUMAN KERATINOCYTES AND MACROPHAGES: POTENTIAL IMPLICATON IN WOUND HEALING**

Andrea Cecilia Parrado (1,2), Luciana Salaverry (1,2), Franco Mangone (1,2), Agustina Sotelo (1,2), Carolina Apicella (2), Natalia Saccodossi (2), Teresa Gentile (2), Andrea Canellada (1,2), Estela Rey-Roldan (1,2)

Dopamine (DA) is a neurotransmitter modulator of the immune system. Against external agents, keratinocytes and macrophages of the cutaneous immune system produce pro-inflammatory cytokines and metalloproteinases (MMP), which are involved in wound healing. Both cells have a catecholaminergic system thought to modulate several processes in the skin such as inflammation and tissue repair. In this work, we evaluated the effect of dopamine (10^{-6}, 10^{-5}, 10^{-4}M) in the presence or absence of the β-adrenergic antagonist propranolol (10^{-5}M) on wound closure (wound scratch assay), MMP activity (MMP-9, zymography), cytokine production (IL-8, IL-1β, ELISA), IκB/NFκB pathway activation (western blot), in a cell line of human keratinocytes HaCaT and THP-1 macrophages (PMA-differentiated cells). We previously demonstrated that DA increased IL-6 and IL-8 production by β-adrenergic receptor in human keratinocytes. In this work, we demonstrated that DA (10^{-5}) did not modify the wound closure in keratinocytes, but decreased the propranolol stimulatory effect ($p<0.05$) delaying the cell migration. MMP-9 activity ($p<0.001$) and propranolol-induced MMP9 activity were decreased by DA ($p<0.05$). In addition, DA (10^{-5}) increase NFκB-p65 levels in nuclear extracts ($p<0.01$), this effect was reduced in presence of propranolol ($p<0.05$), suggesting NFκB pathway is involved in the effect of DA on keratinocytes. On the other hand, DA (10^{-5}) increased MMP-9 activity ($p<0.01$) without affecting the propranolol-induced MMP-9 activity in THP-1 macrophages. DA increased IL-8 production ($p<0.01$), effect that was reduced in presence of propranolol ($p<0.05$). However, DA did not modify NFκB-p65 in nuclear extracts, evidencing the latter pathway is not implicated in the effect of DA in human macrophages. In conclusion, these results suggest a differential effect of DA, via β-adrenergic receptors, that depends on the physiological condition and the cell type involved that could affect the wound healing process.

Keywords: dopamine, beta-adrenergic receptors, keratinocytes, macrophages.

(1736) **CHARACTERIZATION OF THE SUBCELLULAR COMPARTMENT INVOLVED IN HUMAN NEUTROPHIL INTERLEUKIN-1**B **(IL-1 B) SECRETION**

IL-1β is a major proinflammatory cytokine synthesized in the cytoplasm as an inactive precursor that is activated by proteolytic cleavage. It is a leaderless cytosolic protein that is secreted by unconventional mechanisms different from the classical RE-Golgi pathway. We previously determined that human neutrophil IL-1β processing is dependent on caspase-1 and elastase and/or proteinase-3. Our studies also indicated that neutrophil IL-1β is secreted by an unconventional secretory autophagic mechanism. Here we aim to get insights of the subcellular mechanisms that control IL-1β secretion from human neutrophils by employing immunofluorescence staining and confocal microscopy. We determined that after 3.5 h post-LPS+ATP stimulation part of the neutrophil IL-1β colocalized with elastase and myeloperoxidase in a vesicular compartment (n=3). Neutrophil stimulation with LPS+ATP also induced colocalization of caspase-1 with IL-1β (Mander´s coefficient -MC-: 0.52; n=2; at least 80 cells analyzed/experiment), and this effect was potentiated when neutrophils were also subjected to starvation (MC: 0.59). We also found colocalization of IL-1β with the chaperone protein HSP90 (MC: 0.55 and 0.47; full nutrient and starvation, respectively; n=2). Noteworthy, wide vesicles with IL-1β overlapping with HSP90 signals were found protruding from the cell membrane. By employing the fluorescent probe FLICA to track the presence of activated caspase-1 in live cell imaging assays, we detected FLICA signal as defined spots inside cells with a pattern similar to that observed with caspase-1. Additionally, IL-1β did not colocalize with LAMP-2 at either 3.5 or 5 h post-LPS+ATP stimulation (MC: 0.21 and 0.22; n=4, at least 50 cells analyzed/experiment). Our results suggest that IL-1β is packaged in vesicular compartments which can also include caspase-1 and/or elastase where it might be processed or degraded. HSP90 might contribute to IL-1β entry to vesicles different to lysosomes.

Buenos Aires, Argentina

Receptors for the Fc portion of IgG (FcγR) represent a critical link between innate and adaptive immunity. They enable IgG to trigger effector functions such as cytotoxicity and complement activation. In addition to acute disease, Respiratory Syncytial Virus (RSV) bronchiolitis is associated with asthma during infancy. Although the expression and activity of FcγRII (CD32) on neonatal CD4+ T cells could influence their function, it has not been characterized.

Our aim consisted in identifying CD32 expressing T cells in cord blood mononuclear cells (CBMCs) by flow cytometry; as well as to determine whether cross-linking of FcγR by immobilized IgG modulated the pattern of secreted cytokines. Moreover, we also analyze the frequency of CD4+CD32+ T cells in RSV infected infants.

Our data demonstrated that CD4+CD32+ T cells represent ~3.9% ± 0.6 of CD4+ T cells (n=10). In contrast with CD4+CD32- T cells, this subset mainly consists of naive CD45RA+ and CCR7+ cells ($p<0.01$). We also found that CD4+CD32+ T cells showed a higher frequency of CD25+, FOXP3+, and CD16+ (FcγRIII) markers, compared with CD4+CD32- T cells. We then analyzed whether immobilized IgG, could modulate the production of cytokines by CD4+ T cells. Functionally, culture on immobilized IgG did not change the production of IL-2 and IL-8, but significantly enhanced the secretion of IL-5 ($p<0.01$) in comparison with IgG non-stimulated CBMCs. Interestingly, we detected a significant higher frequency of circulating CD4+CD32+ T cells in severe RSV-infected children compared with CBMCs ($p<0.01$; n=15).

Our data suggest that CD32 expression by neonatal CD4+ T cells modulates their functional profile by promoting Th-2 like response. Because, severe RSV infection in early life is associated with asthma, the fact that RSV children expressed higher frequency of CD4+CD32+ T cells might play a role in the harmful immune response during disease.

Tuberculosis (TB) is the second cause of death worldwide, mostly affecting the lungs (pulmonary TB, PTB), although pleural tuberculosis (PLTB) can be a frequent extrapulmonary manifestation. The immune system receives and sends messages to the central nervous system modulating each other through the Hypothalamus Pituitary Adrenal axis and the autonomous nervous system (ANS). When studying patients with PTB or PLTB we have recently shown that both patients groups had increased dopamine plasma levels. To extend this observation and mainly because dopamine effects are strongly dependent on the types of receptors expressed by target cells, we have now analyzed the expression of transcripts (qRT-PCR) for the dopamine receptors (DRs) of type 1 (DR-1 and DR5, both mediating inhibitory effects) and type 2 (DR-2, DR-3 and-DR4; mostly stimulating) in peripheral blood mononuclear cells (PBMC) of patients with PTB (n = 18) and PLTB (n = 12) and healthy controls (HCo; n=16). Both patient groups showed a significant decrease in the transcripts for DR-3 and DR4 ($p<0.05$ for both). Concerning DR, its expression was slightly increased but statistically insignificant in both TB patient groups. The expression of DR5 and DR2 was nearly undetectable precluding any between-group comparisons. Since the ultimate effect of DA on cells is a consequence of the combined action of the DRs, we calculated the DR1/DR3 and DR1/DR4 ratios (inhibition/stimulation) which appeared both increased in PTB and PLTB patients ($p<0.03$, $p<0.001$, respectively). Therefore, that DRs expression profile from PBMCs of TB patients is more compatible with a predominant inhibitory ability respect HCo. These findings along with the previously shown increased dopamine levels, point out to a detrimental effect of the peripheral dopaminergic system on the development of cellular immune responses in TB.

(94) **CYTOTOXIC CD8+CD127- T CELLS LEVES IN HIV INFECTED CHILDREN**

Alejandra Urioste, Georgina Roffe, Estefania Capecce, María Florencia Sanchez, Jeanette Balbaryski, Graciela Barboni, Eduardo Gaddi

Hospital General de Niños Pedro de Elizalde

Introduction: homeostatic expansion of naive and memory T cells subsets require normal IL-7 alpha chain (CD127) expression levels. This molecule is exclusively expressed on T cells, and in HIV (+) adults patients, its down-regulation is associated with increase CD8+ T cells apoptosis rate.

Objective: to determine CD8+CD127- T cells levels in HIV infected children

Material and methods: percentage of CD8+CD127- T cells levels in 66 patients with HIV infection by vertical transmission, in antiretroviral therapy, was studied by flow cytometry (FACSCalibur, BD) and specific monoclonal antibodies. Plasma HIV RNA viral load (VL) was determined by PCR NASBA. A control group (Co) of 10 healthy children was also studied.

Results: according to immunologic categories of Classification System for HIV infected children: LTCD4+percentage levels ≥ 25% (no evidence of suppression), < 24 % (evidence of moderate or severe suppression), and VL: detectable or not (> or < 50 IU/ml), children were divided in four groups. Percentage levels of CD8+CD127- T cells in different groups were: A: (n: 8) (CD4<24%, VL<50 IU/ml): 13±7, B (n: 37) (CD4≥25%, VL<50 IU/ml): 7±4, C

(n: 10) (CD4<24%, VL> 50 IU/ml): 14±2, D (n: 11) (CD4≥25%, VL> 50 IU/ml): 10 ± 4. Co group showed a percentage of LTCD8+CD127- of 5±2 %. A significant increase ($p\leq 0.05$) of CD8+CD127- T cells levels in patients of A, C and D groups, against B and Co children were observed. A significant negative correlation between LTCD4+ and LTCD8+CD127- percentage levels (r: - 0.448, $p\leq 0.05$) was recorded. A significant positive correlation (r: 0.272, $p\leq 0.05$) between VL values and LTCD8+CD127- percentage levels, was also observed.

Conclusion: the increase of loss of CD127 expression on cytotoxic CD8+ T-cells in children with moderate or severe immunosuppression, and its correlation with viral replication and disease progression markers, could be another feature of HIV-associated immune perturbation.

Keywords: CD8+ T cells, CD127, HIV,children.

(968) **FERTILE HYDATIDS AND CO-INFECTION WITH FASCIOLASIS MODULATES THE CYTOKINE PROFILE IN CATTLE WITH CYSTIC ECHINOCOCCOSIS**

Felipe Corrêa (1), Caroll Stoore (1), Mauricio Jiménez (1), Christian Hidalgo (1), Marcela Hernández (2), Rodolfo Paredes (1)

(1) Escuela de Medicina Veterinaria, Facultad de Ecología y Recursos Naturales, Universidad Andres Bello, Santiago, Chile, (2) Departamento de Patología y Medicina Oral, Facultad de Odontologia, Universidad de Chile, Santiago, Chile.

Introduction: During Cystic Echinococcosis (CE), the immune interplay between the parasite and the host is complex, encompassing effective parasite-killing immune mechanisms developed by the host, which in turn are modulated by the parasite. However, there is no report that describes the cytokine profile in animals with different CE fertility status and co-infection with Fasciolasis (FAS). **Material and Methods:** Blood samples were collected from 38 cattle before slaughtered and classified in 5 categories: Healthy, CE fertile, CE infertile, CE infertile + FAS, CE cyst <1cm. IL-18, IL-10 and IFN-γ serological concentration was determined by MULTIPLEX (Millipore™) assay. **Results:** IL-18 serological concentration in animals

with CE fertile had a mean of 0.22 ng/mL, which is almost the double than the other groups. The mean concentration of IL-10 in animals with CE fertile was 0.21 ng/mL, while the rest of the groups were lower. In the other hand, the concentration of IFN-y in CE infertile (0.99 ng/mL) and CE infertile + FAS (1.0 ng/mL) was slightly higher than the other groups. **Conclusion:** The results suggest that fertile hydatids and co-infection with Fasciolasis modulates the cytokine profile in cattle with Cystic Echinococcosis. **Acknowledgments.** Fondecyt-Chile 1161475; Universidad Andrés Bello (DI-1398-16/I, DI-1249-16/RG).

Therapeutic monoclonal antibodies which are effective in other inflammatory diseases such as rheumatoid arthritis are less effective inflammatory bowel disease (IBD). Human Neutrophil Elastase (HNE) is highly expressed in IBD mucosa, especially in ulcerative colitis (UC). The aim of this study was to determine if HNE degrades biologics, rendering them ineffective, and whether its action can be reversed by its natural inhibitor, Elafin.

Biologics (Infliximab, Adalumimab, Etanercept, Vedolizumab) were digested using different concentrations of recombinant HNE, in the absence or presence of Elafin, overnight. Neutrophils where isolated from human blood (4 UC patients and 2 healthy donors) by gradient centrifugation with Na-Dextran solution. Neutrophils where lysed and elastase activity was quantified. Antibody integrity after recombinant or natural HNE digestion was then analysed by western blot, and the functional capacity of the antibodies to neutralise TNF-alpha was tested using recombinant human TNF-alpha and a TNFR reporter cell line. Recombinant and HNE from blood cells fully degrades all anti-TNF-alpha agents and Vedolizumab (anti-α4β7 integrin specific mAb) in a dose-dependent manner (HNE 0.125μg/ml to 5 μg/ml degrades biologics from 6% to 99.9%, respectively). This activity is significantly inhibited by recombinant Elafin ($p<0.001$). Treatment with HNE also partially prevented the ability of the biologicals to inhibit TNF-alpha bioactivity (HNE at 10μg/ml causes 90% reduction of the anti-TNF›s neutralizing ability, while HNE at 5 μg/ml diminishes only 25% their neutralizing activity).

These results may explain some of the reasons for primary non-responsiveness to anti-TNF alpha therapy in IBD patients.

(1387) **HLA- DQ2/ DQ8 AND ANTIBODIES ASSOCIATED TO CELIAC DISEASE IN RISK INDIVIDUALS**

Eliana Agustina Appella, Alejandra Ginaca, Sabrina Rotondo, Maximiliano Dominguez, Patricia Carabajal
Hospital De Niños Ricardo Gutierrez

About 90% Of Celiac Disease (Cd) Patients Carry Hla-Dq2 Or Dq8 Heterodimers. Hla Typing Provides Additional Data In Uncertain Cases And Risk Groups Such As Relatives, Autoimmune Diseases, And Genetic Syndromes. Serological Tests For Anti-Transglutaminase (Tg), Anti-Endomysium (Ema) And Anti-Deamidated Gliadin Peptide (Dgp) Antibodies (Abs) Are A Useful Diagnostic Tool For Its High Sensitivity And Specificity.

Aim: To Determine Frequency Of Hla Dq Alleles Associated With Cd And Its Relation To The Presence Of Specific Abs In Risk Individuals.

Materials And Methods: 83 Patients, Ẋ Age: 7 Years Old (Range: 1-40). Group1:55 Cd Relatives, Group 2: 28 With Associated Diseases Or Clinical Suspicion. Hla -Drb1, Dqa1 And Dqb1 Genes By Polymerase Chain Reaction-Sequence Specific Primers (Pcr-Ssp) (Biodiagene®Typing). Serum Abs Tg And Dgp By Elisa; Ema By Ifa And Iga Levels By Nephelometry.

Results: Alleles Total Frecuency: 62.7% Dqb1*02 (Dq2); 39.8% Dqb1*0302 (Dq8); 45.8% Dqa1*05 (Dqx.5). 78/83 (94%) Patients(P) Carried One Allele Associated With Increased Risk Of Cd And 16/83 (19%) Had Some Specific Abs. **62P Had High-Risk Alleles: 9**P With Double Doses Of Dqb1*02, 8 Had Complete Haplotype Dr3 Dqa1*05Dqb1*02, And Only 3 Had Increased Levels Of Specific Abs; **20**P Showed Dqa1*05Dqb1*02 (One Dose),8 Had Specific Abs (1 With High Titer); **22**P Carried Dqa1*03Dqb1*0302, 2 With Specific Abs; **6**P Had Dr3dqa1*05Dqb1*02/Dr4 Dqa1*03Dqb1*0302, 1 Had High Level Specific Abs; **5**P Showed Dqb1*02/Dqa1*03Dqb1*0302, Without Abs. **16P Had Low-Risk Alleles**: **12**P One Dose Dqb1*02 (3P Had Specific Abs And 1 With High Titer); **4**P Dqa1*05 Without Other Allele Or Abs. We Didn't Find Difference In Abs Or Allele Distribution Between Groups. Clinical Symptoms Were Found In 23/43P, 20P With High-Risk Alleles, Only 6 With Positive Abs.

Conclusions: 74.7% Of Our Patients Carried High-Risk Haplotypes For Cd, With Higher Frequency Of Dq2. Only 6 P Had High Serum Levels Of Cd Specific Abs.

This May Suggest Cd Diagnosis.

(1803) **GALECTIN-1–DRIVEN TOLEROGENIC PROGRAMS AGGRAVATE *YERSINIA ENTEROCOLITICA* INFECTION BY REPRESSING ANTIBACTERIAL INMUNITY**

Roberto Davicino (1), Santiago Mendez-Huergo (2), Ricardo Javier Elicabe (1), Brenda Jofré (1), Juan Carlos Stupirski (2), Karina Mariño (2), Ingo Autenrieth (3), Silvia Di Genaro (1), Gabriel Rabinovich (2)
(1) Imibio-Sl. (2) Ibyme. (3) Institut Of Medical Microbiology And Hygiene Tuebingen.

Yersinia Enterocolitica (Ye) Is An Enteropathogenic Bacterium That Causes Gastrointestinal Disorders. To Subvert The Host's Immune Response, Ye Uses A Type Iii Secretion System And Effector Proteins, Called Yersinia Outer Proteins (Yops), That Modulate Activation And Survival Of Immune Cells. In This Study, We Show That Galectin-1 (Gal-1), An Immunoregulatory Lectin Widely Expressed In Mucosal Tissues, Contributes To Ye Pathogenicity By Undermining Protective Antibacterial Responses. We Found Higher Expression Of Gal-1 In The Spleen And Peyer's Patches (Pps) Of Mice Infected Orogastrically With Ye Compared With Noninfected Hosts ($P<0.01$ In Spleen At Day 5, $P<0.001$ In Pps At Day 5, $P<0.05$ In Spleen And Pps At Day 7). This Effect Was Prevented When Mice Were Infected With Ye Lacking Yopp ($P<0.01$) Or Yoph ($P<0.05$), Two Critical Effectors Involved In Bacterial Immune Evasion. Consistent With A Regulatory Role For This Lectin, Mice Lacking Gal-1 Showed Increased Weight ($P<0.05$) And Survival, ($P<0.001$) Lower Bacterial Load At 5 And 14 D Postinfection ($P < 0.001$, $P < 0.05$, Respectively), And Attenuated Intestinal Pathology Compared With Wild-Type Mice. Thus, Lack Of Endogenous Gal-1 confers protection against Ye infection. Supplementation of recombinant Gal-1 in mice lacking Gal-1 or treatment of wild-type mice with a neutralizing anti-Gal-1 mAb confirmed the immune inhibitory role of this endogenous lectin during Ye infection. Finally, a possible functional interaction between YopP and Gal-1 via YopP glycans is suggested. Thus, targeting Gal-1-glycan interactions may contribute to reinforce antibacterial responses by reprogramming innate and adaptive immune mechanisms.

(1820) **FOLLOW UP DURING 6 YEARS OF 52 PATIENTS WITH SUBCUTANEOUS IMMUNOGLOBULIN TREATMENT BY PUSH AS REPLACEMENT AND IMMUNOMODULATORY THERAPY**

Ileana Moreira, Analía Gisela Seminario, Lorena Regairaz, Liliana Bezrodnik
Centro de Inmunología Clínica Dra. Bezrodnik

Introduction: Several studies have shown that subcutaneous Immunoglobulin (SCIG) is as good as Intravenous Immunoglobulin (IVIG) preventing infections in primary immunodeficiencies (PID), also SCIG has been proposed as an alternative in the immunomodulatory treatment (IT) of many neurological diseases and other diseases and it seems to be as efficient as IVIG.
Objetive: To describe the follow up of 52 patients (p) with SCIG treatment during 6 years in a single center in Argentina. Results: We reviewed the clinical history of two Groups (G) of patients followed in our center, G1: 44p with PID with IG replacement treatment, G2: 8p with IT for different diseases. Mean age: G1 19.4yo (1.25 – 63.4), G2 43 yo (12.5 – 77.2). Among the G1 6p are under 5 yo (mean age 3.2) 23 are between 5 and 18 (mean 10) and 15 are over 18 yo (mean 40.2). The mean time of follow up was 2,98 years. 13 patients were follow for more than 5 years and 26 patients between 1 and 5 years. SCIG was administered at 1 or multiple injection sites by push, in each site a maximum of 20 ml in children and 35 ml in adults. G1: The mean dose was 144 mg/kg/w.G2: Dose was 300 mg/Kg/w. G1: The mean serum IgG level was 1143 mg/dl. Levels were stable over the years. Efficacy: Among the G1 p, the annual rate of infection was 0,19 infections/patient/year. G2: All patients presented remission. Tolerance: 28,8% presented mild episodes related with the injection site and only three p presented 3 systemic adverse reactions in a total of 10,449 infusions. Conclusion: SCIG therapy is safe and effective for replacement treatment in PID patients, even in children under 5 years old. SCIG may be as effective as IVIG in the maintenance therapy in CIDP and other autoimmune diseases. Further systemic clinical studies are needed to better define combination therapy, optimal dosage and application intervals of SCIG.
Keywords: primary immunodeficiencies, immunoglobulin.

Abstract: An estimated one third of the world's population is affected by latent tuberculosis (TB), which once active represents a leading cause of death among infectious diseases. Human immunodeficiency virus (HIV) infection is a main predisposing factor to TB reactivation. Individuals HIV-TB co-infected develop a chronic state of inflammation associated with several metabolic disorders, as hypothalamic-pituitary-adrenal (HPA) axis dysregulation. This results in a hormonal imbalance, disturbing the physiological levels of cortisol and dehydroepiandrosterone (DHEA). DHEA and its oxygenated metabolites androstenediol (AED), androstenetriol (AET) and 7-oxo-DHEA are immunomodulatory compounds that may regulate physiopathology in HIV-TB co-infection. In order to study possible changes in plasma levels of these hormones, we developed an approach based on high performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS). To our knowledge, this represents the first report of their simultaneous measurement in HIV-TB individuals and the comparison with healthy donors, obtaining statistically higher plasma levels of DHEA, AET and 7-oxo-DHEA in patients. Moreover, we found that concentrations of 7-oxo-DHEA positively correlated with absolute CD4+T cell counts, nadir CD4+T cell values and with individuals who presented TB restricted to the lungs. This research contributes to understanding the role of these hormones in HIV-TB and emphasizes the importance of deepening their study in this context.
Keywords: HIV-TB co-infection, 7-oxo-DHEA, HPLC-MS/MS

(610) **ANALYSIS OF PELVIC PAIN DEVELOPMENT, MAST CELL INFILTRATION AND PROSTATE INFLAMMATION IN AN ANIMAL MODEL OF CHRONIC PELVIC PAIN SYNDROME**

Florencia Salazar, María L. Breser, Gloria J. Godoy, Virginia E. Rivero, Rubén D. Motrich
CIBICI-CONICET. FCQ-UNC

Pain and inflammation in the absence of infection are hallmarks in Chronic Pelvic Pain Syndrome (CPPS) patients. In this set, mast cells have been pointed out as key players in pain induction and central sensitization. Although its etiology remains unclear, autoimmunity has been proposed as a cause and animal models of Experimental Autoimmune Prostatitis (EAP) models have long been used for studying CP/CPPS.

Herein, we analyzed prostate inflammation induction, mast cell infiltration and chronic pelvic pain development in EAP in three common laboratory mouse strains presenting with differential susceptibility to autoimmune prostatitis: the NOD mice (highly susceptible), the C57BL/6 mice (moderately susceptible), and the BALB/c mice(resistant).

Chronic pelvic pain development, evidenced by increased tactile allodynia responses, was similar between immunized NOD and C57BL/6 mice, although the severity of leukocyte infiltration and inflammation was greater in the first case. In fact, prostate tissue from NOD mice revealed markedly increased expression levels of inflammatory cytokines and chemokines. Similar results, but to a lesser extent, were observed when analyzing prostate tissue from C57BL/6 mice. However, similarly increased numbers of mast cells, mostly degranulated, were detected in prostate samples from either NOD or C57BL/6 mice. Conversely, minimal prostate leukocyte infiltration and inflammation was observed in immunized BALB/c mice. Besides, they showed no pelvic pain development and the lowest prostate tissue mast cell total counts and in a resting state.

Our results provide new evidence indicating that NOD, C57BL/6, and BALB/c mice develop different degrees of chronic pelvic pain, type and amount of prostate inflammation and mast cell infiltration. Remarkably, chronic pelvic pain development correlated with mast cell infiltration, suggesting that mast cells are inflammatory cells involved in mediating pelvic pain induction.

Keywords: pain, inflammation, prostatitis, mast cells, chronic pelvic pain syndrome.

Abstract: The use of induced reprogramming of somatic cells to produce transgenic animals requires the development of a biotech-

nological platform. In our study, different strategies for the generation of induced pluripotent stem cells (iPSC) of bovine and porcine cells were evaluated. Episomal and lentiviral vectors were used for delivering reprogramming human factors OCT4, SOX2, KLF4 and c-MYC (h-OKSM) into bovine (BEF) and porcine (PEF) embryonic fibroblasts. Cells were cultured in different media containing different supplements: DMEM/F12 with KSR + FGF, E8 medium for culturing on feeder and serum free conditions and finally SB43 medium in which MAPK/ERK, Wnt and TGF pathways are modulated. Episomal vectors (1x, 2x and 4x runs of transfections) failed to generate iPSCs in both species. In these cultures, we detected a gradual loss of expression of exogenous factors. On the other hand, protocols based on the integrative lentiviral vector, STEMCCA, produced porcine iPSC-like cells more efficiently than from bovine cells. The iPSC generated maintained stem cells features and expression of exogenous factors. Inactivation of STEMCCA is still a bottleneck for establishing bonafide iPSC, since culture media tested did not probably maintain endogenous OKSM expression.

Keywords: iPSC-like cells, bovine and porcine fibroblasts, episomes, STEMCCA, lentiviral vectors

(303) **PEROXIDATION OF CANINE ERYTHROCYTE MEMBRANES: RELATION WITH THE OXIDATIVE STRESS CAUSED BY EXERCISE**

Cesar Savignone (1), Patricio Jose Leaden (1), Magdalena Marchionni (2), Pedro Zeinsteger (1), Mauricio Leggieri (1), Alejandro Palacios (1)

(1) Cátedra de Bioquímica - Facultad de Ciencias Veterinarias, Universidad Nacional de La Plata. (2) Laboratorio de Fisioterapia Veterinaria - Facultad de Ciencias Veterinarias, Universidad Nacional de La Plata

Exercise is considered as a condition of excessive generation of reactive oxygen species (ROS), which can produce oxidative stress and pose potential problems, inducing the loss of membrane integrity and cellular dysfunctions. In relation to blood cells, circulating erythrocytes are regularly exposed to stress conditions and are especially vulnerable as they have no membrane repair mechanism or regenerative capacity. The present investigation was carried out to determine the presence of oxidative alterations in the erythrocyte membrane in dogs submitted to a high intensity exercise test by estimating the degree of peroxidation by chemiluminescence in a suspension of lysates erythrocytes incubation with t-butyl hydroperoxide (t-BHP). Samples were taken with the animal at rest before exercise (T0 or rest), at the maximum exercise time (T1 or exercise) and at the end of the recovery (T2 or recovery). Suspension of lysates erythrocytes with hypotonic phosphate buffer were incubated at a final concentration of 0.25 mg/ml total hemoglobin in an in vitro system for 60 min. at 37°C in the presence of 2 mM of t-BHP. Identical aliquots of the preparation were incubated without additions as the control experiment. Peroxidation was measured by monitoring light emission with a liquid scintillation analyzer Packard 1900 TR. Differences were observed in the total values of chemiluminescence throughout the exercise routine, with observed values of 339.620 cpm, 275.290 cpm and 311.630 cpm for T0, T1 and T2 respectively The conclusions of this study are the existence of changes in the erythrocyte membranes of the dogs subjected to physical exertion, probably associated with the release of ROS caused by the exercise.

(47) **SPERM BINDING TO THE OVIDUCT FOR RESERVOIR FORMATION INVOLVES SCAVENGER RECEPTOR CYSTEINE-RICH (SRCR) DOMAINS OF THE GLYCOPROTEIN DELETED IN MALIGNANT BRAIN TUMOR 1 (DMBT1).**

María Lorena Roldán, Juan Manuel Teijeiro, Jimena Inés Ruiz Alvarez, Patricia Estela Marini

Laboratorio de Medicina Reproductiva, FCByF, UNR.

DMBT1 is present in two forms in the lumen and cells of pig oviduct. The membrane form participates of sperm binding for the formation of a reservoir, in which sperm stay quiescent until ovulation. DMBT1 contains several domains: Scavenger Receptor Cysteine-Rich (SRCR), CUB y Zona Pellucida (ZP), all of which may specifically bind different cells and proteins. It exposes Galβ1-3GalNAc and it is generally accepted that carbohydrate recognition is involved in reservoir formation. The aim of this work was to determine which of the domains of DMBT1 are important for reservoir formation. Sperm binding to oviductal cells was challenged *in vitro* after treatment with antibodies specific for each domain. Anti-SRCR was developed against polypeptide aa 203-689 obtained by cDNA cloning, expression in *E. coli*, purification and rabbit immunization. Anti-CUB was developed similarly in previous works for aa 578-803; and anti-ZP was developed using ZP isolated from porcine oocytes. Primary cultures of oviductal epithelial cells were treated with dilutions of the antibodies and pre-immune serum. Sperm were added and bound spermatozoa were counted (quintuplicate). The rate of sperm bound upon antibodies treatment/sperm bound with pre-immune serum was expressed as percentage, using sperm bound without any serum treatment as 100%. Assumption of normality was determined by Shapiro-Wilks test. Linear mixed Models with Heterogeneous Variance or ANOVA and LSD Fisher (software infoSTAT) were used. Only anti-SRCR antibodies inhibited sperm binding (41%, $p<0.05$). Glycosylation prediction (GlycoEP Predicton Service) shows scarce potential sites in SRCR, being the main O- glycosylation motifs at the scavenger interspersed domains that separate SRCRs. The present work does not allow distinguishing if SRCR polypeptide itself or carbohydrates potentially bound to it are responsible for sperm binding, but DMBT1's SRCR motifs are main domains in porcine sperm reservoir formation.

(361) **THE ANTIOXIDANT EFFECT OF LUTEIN PROTECTS AGAINST OXIDATIVE DAMAGE TO PORCINE SPERMATOZOA**

María Belén Ventura (1), Mónica Marmunti (1), Mariana Gavazza (1), Maricel Campagnoni (2), Viviana Piergiacomi (1), Alejandro Palacios (1)

(1) Cátedra de Bioquímica - Facultad de Ciencias Veterinarias, Universidad Nacional de La Plata. (2) Laboratorio de Reproducción Animal-Facultad de Ciencias Veterinarias, Universidad Nacional de La Plata.

Boar sperm is especially susceptible to peroxidative damage generated by oxygen free radicals (ROS). Chemiluminescence (CL) was started incubated porcine sperm in an in vitro system ascorbate $-Fe^{+2}$, a technique that allows to assess oxidative stress in these cells. Lutein is known for its antioxidant effect, it is chemically a dihydric derivative of α-carotene and belongs to the group of xanthophylls. The main objective of this study was to investigate the antioxidants effects of lutein on the boars sperme. The effect of lutein was analyzed by two methods: 1) by addition to in vitro system ascorbate $-Fe^{+2}$ and 2) incubating lutein with porcine spermatozoa. Porcine sperm were incubated in an in vitro system ascorbate $-Fe^{2+}$ dependent, for 120 min. at 37°C in the presence of increasing amounts of lutein (50 μg, 150 μg and 250 μg) per mg of protein, in addition, samples of porcine semen previously were incubated with lutein (0.15 and 0.25 mg / ml) during 24 h at 15 ° C. Peroxidation was quantified in a liquid scintillation counter Packard 1900 TR by chemiluminescence in cpm (counts per minute). Analyzing the effect of lutein by the two previously mentioned methods, was observed that the total cpm/mg protein originated from light emission: chemiluminescence, was lower in samples obtained from lutein group than in the control group (without lutein), with a significance $p < 0,005$. The percentages of inhibition of peroxidation were not concentration dependent. These results show that lutein may act as an antioxidant protecting sperm membranes from oxidative damage.

(1256) ***TRIBOLIUM CASTANEUM*** **(COLEOPTERA: TENEBRIONIDAE): EPICUTICULAR HYDROCARBONS AND A VOLATILE SEX PHEROMONE.**

Juan R. Girotti, Sergio J. Mijailovsky, Cecilia Fusé, M. Patricia Juárez

Instituto de Investigaciones Bioquímicas de La Plata - CONICET - UNLP, Facultad de Ciencias Médicas, La Plata.

The red flour beetle*, Tribolium castaneum* is a model organism for insect development studies and a major stored product pest of agriculture relevance. Insect surface is covered by hydrocarbons (HC) protecting them against chemical and physical aggression. The aim of this study was to identify and quantify the changes in the epicuticular HC of *T. castaneum* through the development cycle, and to investigate the potential presence of a volatile sex pheromone. Component identification was performed by capillary gas chromatography (CGC) coupled to mass spectrometry (MS); adult volatiles were extracted by solid phase microextraction (SPME) and analyzed by CGC-MS. The HC amounts increased significantly from larva to adult. In immature stages, saturated HC are predominant, with chain lengths of 23 to 43 carbons. A significantly different HC phenotype was observed in the adult stage, with large amounts of branched chains of 27 to 31. In this study, small amounts of a novel aldehyde component were detected in males. Females, but not males, were attracted to this chemical in bioassays. The MS analysis revealed a molecular weight of 210, a twelve carbon unsaturated backbone and at least one methyl-branch. Further analyses are ongoing to fully determine the structure. Here we show that *T. castaneum* HC undergo substantive changes through development, suggesting a precise regulation of the biosynthetic enzymes. The complex metabolic pathway for both, the HCs and the sex pheromone probably takes place in different tissues and is initiated by the action of two fatty acid synthases (FASs), with different affinity to incorporate methyl branches in the elongating chain. Five genes encoding FAS were identified in the *T. castaneum* genome. Studies will be started in order to identify the FAS genes responsible for HC and pheromone synthesis. This knowledge will help understand HC biosynthesis and its regulation. The discovery of a sex pheromone is of interest in pest control.

Antimicrobial peptides present in amphibian skin are important functional molecules of the innate immune system and play defensive roles against external risk factors. The emergence of multiple strains of pathogenic bacteria resistant to conventional antibiotics has become a serious problem to public health, requiring the search of novel therapeutic molecules. We identified and characterized AMPs in the skin of adult specimens of *P. somuncurense (Pso)* and *O. occidentalis (Ooc)*. RNA from cephalic-scapular and dorsal skin regions was isolated and their cDNA was obtained. These cDNA were linked to the pCR™4-TOPO vector to transform *E.coli* DH5α into competent cells. We analyzed and sequenced positive clones, obtaining 11 prepropeptides that codified mature peptides with promising physicochemical features and novel structures. Several presented positive net charge, α-helix structure predicted by 3D software and amphipatic arrangement of the α-helix, which promote their mechanisms of action. Two peptides were similar to the thaulin family peptides, previously described by our group in the skin of the Patagonian frog *Pleurodema thaul*, while the remaining showed 32-53% percent of similarity when compared with other amphibian AMPs. The peptide synthesis in progress aims at characterizing and evaluating their antimicrobial, hemolytic and cytotoxic activity. Histological analysis of Ooc skin revealed the presence of ordinary mucous glands (OMG) and ordinary serous glands (OSG) in the six studied body regions. Both types of glands shared structural traits common in anurans. OMGs were homogeneously distributed, whereas OSGs showed an heterogeneous distribution and were more numerous in the scapular region. The discovery of these peptides is a promising result in the search of new antimicrobials and highlights the potential of Patagonian species as a novel source of AMPs.

Keywords: Antimicrobial peptides, cDNA, frog skin, glands

(135) **EVOLUTIONARY TRENDS IN *Pomacea* EGG CAROTENOPROTEINS INVOLVED IN A BIOCHEMICAL DEFENSE SYSTEM**

Maria Yanina Pasquevich, Marcos Sebastián Dreon, Horacio Heras
INIBIOLP (CONICET-UNLP)

The evolution of structure-function relationship of hyperstable proteins is poorly understood. Studying *Pomacea* snail carotenoproteins as a model, we observed that those involved in embryo nutrition and defense have changed during genus evolution: while brightly colored ones of the most derived clade (*P. canaliculata* and *P. maculata*) act as antinutritive defenses against predators; those of *P. scalaris*, pale, additionally possess a strong lectin activity. The aim of this work was to analyze the evolutionary trends of *Pomacea* carotenoproteins, studying PpPV1, the carotenoprotein of *P. patula*, a basal member of the genus. PpPV1 absorption spectrum shows a 380 nm maximum indicating a blue-shift from the basal clade compared with the derived species (430 – 510 nm). Electrophoretic mobility also shifted from a mobility equivalent to a 450 kDa protein in native PpPV1 towards lower MWs in the most derived carotenoproteins (293 – 380 KDa). Despite these differences, PpPV1 have similar subunits MW to those of its derived species homologues. Derived clades are kinetically stable (a high energetic barrier that not allow passing from native to denaturized state). This characteristic was evaluated in PpPV1 hypothesizing that was acquired in derivative clades in species with notable reproductive success. However, PpPV1 oligomer withstands boiling and is resistant to SDS-induced denaturation, highlighting that carotenoproteins of *Pomacea* eggs are already thermal and kinetically stable in the most basal species. Functional analysis of hemagluttinating activity revealed that *P. patula* periviteline fluid surrounding the embryo has a moderate lectin activity that is not mainly ascribed to PpPV1. In conclusion, the comparative analysis shows that, while carotenoprotein color and size changed, subunits and structural stability was conserved. The later may have increased tolerance to mutations that accelerated the evolution of new functions.

Keywords: perivitelines, mollusca, kinetic stability

(1047) **THIOL REDOX HOMEOSTASIS IN VISUAL CORTEX IN AN EXPERIMENTAL GLAUCOMA MODEL**

Claudia Gabriela Reides, Agustina Peverini, Ailen Hvozda Arana, Natasha Janezic, Romina Mayra Lasagni Vitar, Fabian Lerner, Sandra Maria Ferreira, Susana Francisca Llesuy
Cátedra de Química General e Inorgánica. IBIMOL, UBA-CONICET. Facultad de Farmacia y Bioquímica. UBA.

Abstract: Alterations in thiol redox homeostasis have been implicated in the pathology of neurodegenerative diseases. Recent evidence has detected neurodegenerative lesions in glaucomatous optic nerve, lateral geniculate nucleus and visual cortex, suggesting that glaucoma should be considered a neurodegenerative disorder.

The aim of this work was to evaluate thiol redox homeostasis in visual cortex in a glaucoma rat model. Female Wistar rats (3 months) were divided in two groups (n=12): glaucoma in which rats were operated under a microscope by cauterized two of the episcleral veins (G) and control which received a sham procedure (C). Seven days after surgery rats were euthanized, brains were removed and visual cortex was separated.The following markers were evaluated: glutathione reductase (GR), glutathione peroxidase (GPx), reduced glutathione (GSH), oxidized glutathione (GSSG), redox index (GSH/GSSG), glucose-6-phosphate deshidrogenase (G6PD) and thioredoxin reductase (TrxR)

Comparing glaucoma to control: GR diminished 52% (C: 13.0 ± 1.0 nmol/min.mg protein *p<0.001*), GPx increased 56% (C: 0.079 ± 0.007 μmol/min.mg protein *p<0.05*), GSH decreased 46% (C: 7.02 ± 0.39 **μmol/g** *p< 0.001*), GSSG increased 26 % (C: 0.35 ± 0.020 μmol/g, *p< 0.05*), redox index diminished 57% (C:20.0 ± 1.8

p< 0.001), G6PD decrease 45% (C: 0.18 ± 0.02 mmol/min.mg protein *p<0.01*) and TrxR decreased 34% (C:14.9 ± 0.8 nmol/min.mg protein *p<0.001*).

The decrease in GR activity as well as the increase in GPx activity would lead to a decrease in GSH and an increase in GSSG. Moreover, this situation is exacerbated by the decrease in G6PD activity which provides the NADPH needed by GR to regenerate GSH. Besides thioredoxin is recycled at the expense of NADPH by TrxR, though the decrease in NADPH and in TrxR activity could lead to a decrease in thioredoxin which reduces disulphide bonds of proteins. Results allow concluding that thiol redox homeostasis is altered in visual cortex in a glaucoma model.

Keywords: glaucoma, glutathione, redox homeostasis, visual cortex, oxidative stress

(778) **SEARCHING FOR THE MOLECULAR PATHWAYS INVOLVED IN CERAMIDE-INDUCED DEATH OF RETINA PHOTORECEPTORS**

Facundo Heber Prado Spalm (1), Marcela Vera (1), Marcos Dibo (1), Luis Enrique Politi (1), Nora Patricia Rotstein (1)
(1) Instituto de Investigaciones Bioquímicas de Bahía Blanca (INIBIBB) - Universidad Nacional del Sur (UNS).

Programmed cell death of photoreceptors (PhR) is a hallmark of neurodegenerative diseases of the retina, irrespective of their cause. Identifying the mediators and molecular mechanisms involved is essential for designing new treatments. Ceramide (Cer), a simple sphingolipid, signals cell death in many cell types. Our laboratory demonstrated that it induces PhR death in culture and Cer was then shown to participate in different retina pathologies. We now investigated the molecular mechanisms involved in this death.

Rat retina neuronal cultures were treated at day 3 with or without 10 μM C2-Ceramide (Cer) for 6 hours. Cer decreased neuronal viability to 50%, as determined by MTT assays. Cer selectively increased PhR with pyknotic nuclei to 50 %, compared to 5 % in controls, without augmenting their TUNEL labeling, whereas amacrine neurons were not affected. Cer decreased PhR mitochondrial functionality and promoted AIF translocation from mitochondria to nuclei. Noteworthy, no cleaved-caspase 3 increase was observed; pretreatment with Z-VAD-FMK, a caspase pan inhibitor, failed to prevent PhR death, suggesting this death was caspase-independent. Cer did not increase LDH release and a necroptosis inhibitor did not protect PhR, implying programmed necrosis was not involved. Autophagy was also ruled out, as the autophagy inhibitor 3-MA did not prevent Cer-induced death. Next, we investigated the involvement of cathepsins and calpains. Pretreatment with ALLN, a calpain and cathepsin inhibitor, significantly increased viability from 50% in Cer-treated cultures to over 80%, decreasing the percentage of pyknotic PhR. Of note, inhibiting both cathepsins (Pepstatin A, CA-074) and lysosomal activity (Bafilomycin A1) did not block PhR death.

As a whole, our results suggest that Cer promotes programmed cell death in PhR in a caspase-independent manner, activating calpain proteases, and inducing mitochondrial permeabilization followed by translocation of AIF and nuclear pyknosis.

(467) **ROLE OF THE PURINERGIC RECEPTOR P2X7 IN THE REGULATION OF THE PROLIFERATIVE, VASCULAR AND INFLAMMATORY RESPONSE IN THE INJURED RETINA OF ADULT ZEBRAFISH**

Matias Pedro Medrano, María Paula Faillace
Instituto de Fisiología y Biofísica Bernardo Houssay (IFIBIO-Houssay), UBA-CONICET.

Unlike mammals, zebrafish can regenerate retinal neurons to replace those lost by injury or disease. Müller glia in mammals responds with hypertrophy and scarring. Injury-responsive Müller cells in zebrafish show limited gliosis and cell cycle reprogramming to repair the retina. The P2X7 purinergic receptor (P2RX7) has been involved in the genesis of retinopathies in rodents and humans. We characterized a hypoxia-like injury by delivering $CoCl_2$ intraocularly that virtually kills all photoreceptors in the zebrafish retina. So we examined here the *in vivo* regenerative response of $CoCl_2$-injured retinas in the presence or absence of a specific P2RX7 antagonist (A740003). We quantified the number of proliferative progenitor and microglial cells. We labeled endothelial cells and assessed GFAP immunoreactivity. Quantitative mRNA expression of different hypoxia-induced genes and cell proliferation-related genes was also analyzed by RT-qPCR.

Lesioned retinas treated with A740003 showed a significant increase in the number of proliferative progenitors including a larger number of dividing nuclei of the GFAP-positive Müller glia. The number of microglial cells around vessels and proliferation-related gene expression were also significantly enhanced. Vascular endothelial growth factor and its receptor and Hypoxia-induced factor genes were differentially expressed in the antagonist-treated retinas. Likewise, apyrase-treated injured retinas exhibited a larger number of proliferative cells while the number of apoptotic cells increased in all retinal layers and that of bipolar cells displayed a significant decrease.

The antagonist of P2X7R enhanced overall injury severity. Similar results were observed when extracellular nucleotides were eliminated by an excess of intraocular apyrase. These findings suggest that the P2X7R plays a crucial neuroprotective role in the zebrafish retina since the selective blockade of its activity had a deleterious impact on the injured tissue.

(1180) **RETINAL NEUROPROTECTION AGAINST ACUTE RETINAL ISCHEMIA INDUCED BY ISOLATED VISUAL STIMULATION IN ADULT RATS**

Georgia Milne, Hernan Dieguez, Maria Florencia Gonzalez Fleitas, Marcos Aranda, Agustina Iaquinandi, Pablo Sande, Monica Chianelli, Maria Ines Keller Sarmiento, Ruth Rosenstein, Damian Dorfman
Laboratorio de Neuroquímica Retiniana y Oftalmología Experimental, Dpto. de Bioquímica Humana, Facultad de Medicina, UBA, CEFyBO-CONICET.

Enriched environment (EE) is a complex combination of inanimate and social interaction. EE boosts exploratory conduct, voluntary physical exercise, sensorial and cognitive functions, and social interaction. We have previously shown that EE induced neuroprotection against unilateral retinal ischemia in adult rats. However, the relative contribution of each component to the effects of EE is still controversial. Our aim was to dissect the individual contributions of the EE repertoire components in its protection against retinal ischemia. Adult male *Wistar* rats were subjected to unilateral or bilateral retinal ischemia and afterwards housed in stardard environment (SE), EE, social environment (SoE), novelty environment (NE), or visual environment (VE). SE consisted in stardard laboratory cages housing 2 animals/cage. EE consisted in big cages (100 x 50 x 82 cm) housing 6 animals/cage with a variety of objects, tunnels and running wheels daily relocated and weekly replaced. SoE and NE consisted in SE housing 5 animals/cage, and EE objects respectively. VE consisted in SE cages surrounded by monitors showing black/white contrast (or grey patterns as controls) during the 12 h light phase. An antagonist for brain-derived neurotrophic factor (BDNF) Trk-b receptor (ANA-12) was administered to animals with unilateral retinal ischemia exposed to black/white contrast patterns. Retinal function (electroretinography) and histology were analyzed 3 weeks after ischemia. Retinal ischemia induced functional and histological alterations ($p<0.01$), which were not protected by SoE or NE. The retinal protection achieved by EE against unilateral ischemia ($p<0.01$) was abolished when ischemia was induced bilaterally, regardless of motor activity. The exposure to VE achieved retinal protection against unilateral ischemia ($p<0.01$), which was prevented by ANA-12. These results suggest that visual stimuli, likely in a BDNF dependent manner, could account for the retinal protection induced by EE.

(800) **MIGRATION OF RETINAL PIGMENT EPITHELIUM CELLS IS REGULATED BY SPHINGOSINE-1- PHOS-**

PHATE

Maria Victoria Simón (1), Marcela Vera (1), Facundo Prado Spalm (1), Nora Patricia Rotstein (1)
(1) INSTITUTO DE INVESTIGACIONES BIOQUÍMICAS DE BAHIA BLANCA (INIBIBB).

Abstract: Retina proliferative diseases, such as diabetic retinopathy, are common causes of blindness. They are characterized by increased migration of two cell types that normally support retinal function: retinal pigment epithelium (RPE) and Müller glial cells (MGC). We previously found that sphingosine-1-phosphate (S1P), a bioactive lipid, increases MGC migration (Simon et al; 2015). Now we analyzed if S1P also regulates RPE cell migration.

Cultures of ARPE19 cells, a human retinal pigment epithelial cell line, were supplemented with 5 μM S1P and migration was evaluated by scratch-wound assays. To investigate whether ARPE19 cells synthesized S1P to promote migration, cultures were treated with 30 μM sphingosine kinase 1 inhibitor 2 (SphKI2), a SphK1inhibitor. To analyze the role of PI3K and ERK/MAPK signaling pathways in cell migration, cultures were pre-incubated with10 μM LY294002 and 10 μM U0126 -a PI3K and ERK/MAPK inhibitor, respectively- before S1P supplementation.

S1P addition significantly enhanced RPE cell migration; after 24hours, migration in S1P- supplemented cells doubled compared to control conditions. Pre-treatment with SphKI2 reduced by 30% the migration observed in controls, implying endogenous synthesis of S1P promoted RPE cell migration. Addition of exogenous S1P to SphKI2- treated cultures partially restored cell migration, suggesting S1P acts as an intra and extracellular cue. Finally, S1P activated both PI3K and ERK/MAPK signaling pathways to induce ARPE migration. Cultures pre-treated with LY294002 or U0126 and then with S1P barely showed 3% and 0.1%, respectively, of the migration observed in S1P-supplemented cultures.

Our results suggest that RPE cells synthesize S1P, which activates PI3K and ERK/MAPK pathways to induce migration and the increase in S1P levels exacerbates this migration. Since deregulation of thisprocess is involved in several retinal pathologies, modulation of S1P signaling emerges as a potential tool for treating these diseases.

Key words: migration, retinal pigment epithelium, retina, sphingosine-1- phosphate

(463) **MICROARRAY ANALYSIS OF GENE EXPRESSION IN HUMAN MÜLLER CELLS IN RESPONSE TO HYPOTONICITY**

Vanina Netti (1), Gerardo Ramos-Mandujano (2), Paula Ford (1), Claudia Capurro (1)
(1) Laboratorio de Biomembranas, IFIBIO-HOUSSAY, Facultad de Medicina, Universidad de Buenos Aires. (2) Instituto de Fisiología Celular, Universidad Nacional Autónoma de México.

Müller cells are involved in controlling extracellular homeostasis in the retina, where neural activity alters osmotic gradients, leading to cell swelling and consequently to a regulatory volume decrease (RVD) response. We previously demonstrated in human Müller cells (MIO-M1) that RVD depends on the efflux of KCl, Taurine and Glutamate, followed by water outflow through Aquaporin-4 (AQP4). Hypotonic shock (HS) also induces a slight transient increase in intracellular Ca^{2+} levels and membrane depolarization and repolarization. However, the mechanisms for long-term adaptation to hypotonicity are largely unknown. Thus, the aim of this study was to identify HS-related changes in gene expression triggered by cell swelling. Gene transcription by MIO-M1 cells exposed to control or HS (ΔOsm:100 mOsm) for 30 minutes was compared using Affymetrix microarray for 10000 genes. Microarray data analysis was performed with GenArise software and DAVID Bioinformatics Resources 6.8 Database. HS induced the upregulation (Z-score>2SD) of 241 genes and downregulation (Z-score<-2SD) of 264 genes. Among HS-upregulated genes were those involved in membrane transport, glucose homeostasis, intracellular signaling events and neurotransmitter secretion. In particular, several members of the solute carriers SLC familiy involved in transport of neurotransmitters and organic/inorganic compounds were upregulated. Genes which decreased their expression were mainly those involved in cell growth regulation, cell proliferation and apoptosis. AQP4 was also downregulated, probably to prevent further swelling. Metabolic pathways affected by HS, including up and downregulated genes, were mainly those concerning neuroactive ligand-receptor interactions and Glutamine/Glutamate metabolism. HS-responsive genes regulation, which probably lead to adaptive changes in Müller cells physiology, may be important for maintaining retinal extracellular environment homeostasis under conditions of sustained hypotonicity.

Keywords: Müller cells – hipotonicity – gene expression

(89) **LIGHT-INDUCTION OF THE ENZYME ARALKYLAMINE N-ACETYLTRANSFERASE (AANAT) IN THE CHICKEN INNER RETINA AND ITS POTENTIAL PHYSIOLOGICAL ROLE**

Mario Eduardo Guido, Maximiliano Rios
CIQUIBIC CONICET FCQ Universidad Nacional de Córdoba.

The neurohormone melatonin is synthesized from serotonin through two steps of which serotonin is converted first to N-acetyl-serotonin (NAS) by the enzyme Aralkylamine N- Acetyltransferase (AANAT). AANAT is present mainly in the pineal gland, retina and other regions while NAS can activate the TrkB receptor to generate neuroprotective effects and neurogenesis. Melatonin synthesis is controlled by light (L) and the circadian clock. In photoreceptor cells, AANAT activity peaks during the dark and at subjective night while activity is significantly decreased by L exposure. By contrast, melatonin synthesis, AANAT expression and activity are high during the subjective day or L phase in chicken retinal ganglion cells (RGCs) (Garbarino et al 2004). Here we investigate the expression of AANAT and of nonvisual opsins in highly enriched RGC cultures obtained from embryos by a discontinuous BSA gradient, and exposure to different L conditions. Cultures expressed melanopsins, Opn3 and Opn5 which may confer intrinsic photosensitivity. In fact, cultures exhibited blue L induction of AANAT immunoreactivity as compared with dark or red L treated cells. In addition, expression of this enzyme was significantly increased by forskolin (10 uM), an adenylate cyclase activator, in the dark. Results suggest that AANAT is a blue L-induced enzyme in RGCs controlled by cAMP. Further studies will investigate the cascade controlling AANAT expression in RGCs and its effects on retinal cells.

Palabras clave: melatonin, retina, acetyl-serotonin, light induction, neuroprotection

(1739) **LACK OF GALECTIN-1 PREVENTS BIOCHEMICAL AND FUNCTIONAL ALTERATIONS IN A MOUSE MODEL OF OXYGEN-INDUCED RETINOPATHY**

Magali Evelin Ridano (1), Paula Virginia Subirada (1), Maria Constanza Paz (1), Diego Omar Croci Russo (2), Gabriel Adrian Rabinovich (2), Maria Cecilia Sánchez (1)

Abstract: Neovascular retinopathies are leading causes of irreversible blindness. Although vascular endothelial growth factor (VEGF) inhibitors have been established as the mainstay of current treatment, clinical management of these diseases is still limited. Previously we showed that Galectin-1 (Gal1) is involved in vascular and non-vascular alterations associated with retinopathies, using the oxygen-induced retinopathy (OIR) mouse model. Postnatal day 17 OIR mouse retinas showed the highest neovascular profile and VEGF levels and exhibited neuro-glial injury as well as retinal functional loss, which persisted until P26 OIR. Concomitant to VEGF up-regulation, Gal1 was highly expressed in P17 OIR retinas. Whereas VEGF returned to baseline levels at P26, increased Gal1 expression persisted until this time period. Here, we evaluated vascular and non-vascular alterations in Gal1-deficient (*Lgals1*$^{-/-}$) OIR mice. Briefly, C57BL/6 wild type (WT) and *Lgals1*$^{-/-}$mice were exposed to 75% O_2 from P7 to P12, after which they were brought to room air for additional five (P17) or nine days (P26). At P17 and P26

mice were sacrificed. Some eyes were fixed to obtain cryosections and retinas were isolated from others to analyze VEGF, glutamine synthase (GS) and glial fibrillary acidic protein (GFAP) expression by Western blots. Finally, retinal function was analyzed by electroretinography. GraphPad Prism program was employed for statistical analysis. Results showed that *Lgals1*$^{-/-}$ P17 OIR had less VEGF protein levels than WT P17 OIR retinas. Besides, *Lgals1*$^{-/-}$ P26 OIR showed a reduction in GFAP expression compared with WT P26 OIR retinas. Moreover, *Lgals1*$^{-/-}$ OIR retinas did not show any alterations in GS expression and the OIR retinal functional defects were partially prevented in these mice. Thus, Gal1 play a key role in the pathogenesis of neovascular retinopathies and could be postulated as a novel therapeutic target.

The therapeutic potential of enriched environment (EE) against damage induced by neuroinflammation has been scarcely studied. Optic neuritis (ON) is an inflammatory, demyelinating and neurodegenerative disease of the optic nerve that can cause irreversible blindness. We studied the effect of EE housing on visual pathway damage induced by experimental ON. Vehicle or LPS were micro-injected into the optic nerve of adult male *Wistar* rats. After injection, one group of animals was housed in EE and another group remained in standard laboratory cages (SE) for 21 days. EE prevented ON-induced decrease in consensual pupillary reflex (PR), visual evoked potential amplitude, and anterograde transport. Moreover, EE prevented the decrease in phosphorylated neurofilament-immunoreactivity, microglial reactivity and astrocytosis, and reduced demyelination and prevented retinal ganglion cell and axon loss induced by LPS injection ($p<0.01$). EE prevented the increase of oxidative damage and protein levels of nitric oxide synthase-2 and cyclooxygenase-2, as well as the levels of interleukin-1β mRNA and TNFα induced by experimental ON ($p<0.01$). In addition, EE housing increased brain-derived neurotrophic factor levels ($p<0.01$). When EE exposure started at 4 (but not 7) days post-injection of LPS, a protection of RP was observed at 21 days post-LPS, which was blocked by daily administration of ANA-12 (a Trk-B receptor antagonist) from day 4 to day 7 post-injection of LPS ($p<0.01$). Exposure to EE from day 4 to day 7 post-injection significantly preserved the PR at 21 days post-injection ($p<0.01$).These results indicate that EE housing reduces neuroinflammation of the optic nerve and preserves visual functions.

(1470) **DEGENERATIVE AND ANGIOGENIC EFFECTS OF HYPERTHYROIDISM ON THE ADULT ZEBRAFISH RETINA**

Claudio Alejandro Bejarano, Maria Paula Faillace
Departamento de Fisiología y Biofísica, Facultad de Medicina, UBA e Instituto de Fisiología y Biofísica Bernardo Houssay, IFIBIO Houssay, CONICET-UBA

Alterations of the neuro-glio-vascular unit underlie different pathologies of the CNS, including retina pathologies. Adult zebrafish (ZF) are able to regenerate tissues and organs being a suitable model to study the regulation of cell genesis and differentiation.

We examined the effect of hyperthyroidism induced by exposure to elevated levels of T4 on repairing the neuro-glio-vascular circuit during retina regeneration in the ZF.

Retinas of a group of ZF were injured with an intravitreal injection of ouabain whereas control groups were injected with saline. Then, the animals were separated into four groups: 2 groups (injured and saline) were treated with T4 (300 µg /L)and other two groups (injured and saline)were treated with vehicle (0.1 M NaOH) in the tank water up to 25 days after injury (dpi). Euthanasia was done and retina sections were obtained at 25 dpi. Double immunofluorescence was performed to detect different cell populations and vascularization in the retinal tissue. mRNA levels of Thyroid hormone receptors (TRs), VEGF receptors (VEGFRs) and cell-type markers in the retina were detected by quantitative RT-PCR.

Retina neovascularization was observed in the groups exposed to elevated levels ofT4 either injured or not injured. Analysis of virtually all cell populations and their synaptic connections showed a significant decrease in cell number as well as in the dimension of synaptic layers in lesioned ZF. mRNA relative expression of TRs and VEGFRs showed significant changes depending on the receptor type. mRNAs of cell markers correlated with the observed morphological changes.

In conclusion, an exacerbation of the TH signaling system induces severe inhibition of retina cell regeneration and tissue growth alterations. Moreover, high T4 levels induced retina neovascularization. The changes observed in both injured and T4-treated retinas in the long term are compatible with processes described in neurodegenerative and neovascularizing retinopathies.

The Cys residues are almost perfectly conserved in all antibodies. They contribute significantly to the antibody fragment stability. The relevance of two natural contiguous Cys residues of an antirecombinant human follicle stimulation hormone (rhFSH) in a format of single-chain variable fragment (scFv) was studied. This scFv derived from a monoclonal antibody (mAb) that naturally contains 5 Cys residues: VH22 and VH92 in the variable heavy chain (VH) and VL23, VL87 and VL88 in the variable light chain (VL). The influence of Cys at positions VL87 and VL88 was studied by considering the wild type fragment and mutant variants: C88S, C87S, and C87Y. The analysis was carried out using antigenbinding ability measurement by indirect specific ELISA and a detailed molecular modeling that comprises homology methods, long molecular dynamics simulations (MD) and docking. We found that Cys VL87 affected the antibody fragment stability and its ability to bind the antigen without interfering with the disulfide bond formation. In the C88S mutant, the CysVL87 was not able to replace the Cys VL88 role and the antibody loss its ability to bind rhFSH. Nevertheless, C87S and C87Y mutants increased the ability of the antibody to bind rhFSH. From the molecular dynamics study we found that the mutant C87Y caused a conformational change in the VH-CDR3 loop, increased flexibility of the V_H-CDR2 and V_HCDR3 loops and a relative rotation of the VH and VL domains. These changes also comprised the increment in the total number of interchain hydrogen bonds that brings more stability to the multidomain structure. The docking simulations of the wild type scFv, C87S and C87Y mutants on hFSH proposed that the last variant has the larger probability to bind the target. The docking studies also suggested that the paratope loops with larger interaction with the epitope are V_HCDR2, V_HCDR3 and therefore are prone to be affected by the conformations or mobility of these zones.

SORBENT ASSAY FOR THE DETECTION OF RAW AND PROCESSED BOVINE BETA-CASEIN

Daniela Susana Castillo, Alejandro Cassola
Instituto de Investigaciones Biotecnológicas Dr. Rodolfo A. Ugalde, Instituto Tecnológico de Chascomús (IIB-INTECH), Universidad Nacional de San Martín, CONICET, San Martín, Buenos Aires, Argentina.

Abstract: Cow milk protein allergy (CMPA) is the most common childhood food allergy, which can sometimes persist or can newly develop in adulthood with severe symptoms. CMPA's treatment is complete dietary avoidance of milk proteins. To achieve this task, patients have to be aware of milk proteins found as "hidden allergens" in food commodities. In regard to milk proteins, it has been reported that allergenicity of caseins remains unaffected upon heat treatment. For these reasons, we aimed to obtain monoclonal antibodies (mAbs) against native and denatured β-casein, one of the most abundant and antigenic caseins, in order to develop an indirect competitive ELISA (icELISA) to detect and quantify traces of this milk allergen in raw and processed foodstuffs. We developed two specific hybridoma clones, 1H3 and 6A12, which recognized β-casein in its denatured and native conformations by indirect ELISA (iELISA). Cross-reaction analysis by Western blot and iELISA indicated that these mAbs specifically recognized β-casein from bovine and goat milk extracts, while they did not cross-react with proteins present in other food matrixes. These highly specific mAbs enabled the development of sensitive, reliable and reproducible icELISAs to detect and quantify this milk protein allergen in food commodities. The extraction of β-casein from foodstuff was efficiently carried out at 60°C for 15 minutes, using an extraction buffer containing 1% SDS. The present study establishes a valid 1H3 based-icELISA, which allows the detection and quantification –0.29 ppm and 0.80 ppm, respectively– of small amounts of β-casein in raw and processed foods. Furthermore, we were able to detect milk contamination in incurred food samples with the same sensitivity as a commercial sandwich ELISA thus showing that this icELISA constitutes a reliable analytical method for control strategies in food industry and allergy prevention.

Human infection with Shiga toxin-producing *Escherichia coli* (STEC) is a major cause of postdiarrheal hemolytic uremic syndrome (HUS). The ability to produce Shiga toxins (Stx1 and/or Stx2) are the key virulence trait of STEC strains, and the O157:H7 and non-O157:H7 STEC strains can produce both or only one of the two types of toxins in their different variants (Stx1: Stx1a, Stx1c and Stx1d; Stx2: Stx2a, Stx2b, Stx2c, Stx2d, Stx2e, Stx2f and Stx2g). Therefore, Shiga toxins detection assays are considered the most suitable methods for diagnosis of STEC-associated diseases. In this work, we developed two capture ELISAs for Stx1 and Stx2 detection from broth culture and stool samples. In a first approach, we exploited nanobody technology for the development of a double nanobody capture ELISA for Stx2a detection, the most prevalent variant of Stx2. Using this immunocapture nanobody-based ELISA, we were able to detect the native toxin from culture supernatants of STEC strains expressing Stx2a and from stools samples obtained from HUS patients. In order to detect the entire repertory of Shiga toxin variants, we developed a capture ELISA based on a F(ab´)$_2$ fragments that specifically recognize Stx1 and Stx2. The F(ab´)$_2$ fragments were obtained from the peptic digestion of IgGs obtained from horses immunized with the recombinant proteins BLS-Stx1B and BLS-Stx2B (Brucella Lumazine Synthase-B subunit of Stx1 and 2). Using this approach we were able to detect with high sensitivity Stx1a and Stx1c as well as the Stx2 variants Stx2a, Stx2b, Stx2c and Stx2f greatly expanding the Stx detection spectrum. Both immunocapture assays are novel diagnostics that allow a sensitive and specific detection of Shiga toxins and may be of great value for diagnosis of HUS associated with STEC. Furthermore, the nanobodies and F(ab')$_2$ fragments evaluated in this work may constitute excellent diagnostic tools for the development of simple, rapid and accurate lateral flow immunoassays.

Keywords: Hemolytic Uremic Syndrome, Shiga toxins, STEC, diagnostics, nanobodies.

(679) **GENERATION OF EIAs (ENZYME IMMUNEASSAYS) FOR LOCAL AND REGIONAL VIRAL DISEASES**

Sandra Goñi (1), Matías Lorch (1), María Soledad Collado (1), Rosana Rota (1), Marcelo Argüelles (2), Agustín De Ganzó (1), Mercedes Pastorini (1), Valeria Adoue (1), Mirna Sánchez (1), María Alejandra Morales (3), Juan Manuel Marengo (4), Alicia Alonso (4), Lorena Spinsanti (5), Gabriel Iglesias (1), Mario Lozano (1)

(5) Lab. de Arbovirus, InViV, UNC, Argentina.

The aim of the laboratory is establish a workflow that converges in enzyme immuneassays (EIAs) for serological identification of several viral infectious agents that have local and regional importance, with implications in diagnostic and epidemiological surveillance. It is very important to recognize the relevant antigens of the viruses of interest. In this way, we determine the more important epitopes using immunobioinformatics tools, and proceed to work with versions of recombinant proteins, produced in a bacterial system. These proteins are: HT-NS1SLEV, HT-NS1DENV-1, HT-NS1WNV, HT-NS1ZIKV, HT-NS1YFV, HT-NS1-EpSLEV, HT-NS5SLEV, HT-VP1B19, and HT-L1HPV. Alternatively, we have an antigen presentation design based on Z protein of JUNV for mammal's cells that can be use complementarily. The entire sequence of NS1SLEV was included to this system, obtaining VLPs that are being analyzed in their composition. Therefore, the HT-NS1SLEV protein was used to inoculate mice and evaluate the humoral response α-NS1SLEV, and start the protocol for monoclonal antibody generation, a fundamental component that ensures the specificity and quality of the kits. To the EIAs is necessary to purify the IgGs or MAbs. For this, we are working in an affinity chromatography that replaces the commercial acquisitions, reducing the production costs. The first step is the production of the affinity protein in a bacterial system, and then this protein will be couple to the matrix. The local EIAs kits development is an important work area to be cover in our countries. The availability of these tools at health institutions gives access to a correct diagnosis and to the registration of epidemiological data useful for planning plague control strategies, between other things.

Abstract: Melanoma is the deadliest form of skin cancer. There

has been a paradigm shift in the treatment of melanoma based on the development of targeted therapies and immunotherapies showing unprecedented survival benefits. However, responses are not universal and patients who initially respond develop acquired resistance. Critically, treatment is associated with inflammatory toxicity and high cost. Therefore, determining which patients would derive clinical benefit from immunotherapy is a compelling clinical question. The aim of this study was to determine predictive molecular biomarkers of response to immunotherapy and to quantify the cellular composition of the immune response in order to investigate its relationship with response to treatment. We analyzed the gene expression profiles of melanoma tumor samples from databases with clinical annotation such as The Cancer Genome Atlas (TCGA, n=470), The Cancer Immunome Atlas (TCIA) and public datasets from Gene Expression Omnibus (GEO). For this meta-analysis we implemented an established computational approach (CIBERSORT) based on a deconvolution method to infer the proportion of 22 immune cell types from gene expression profiles. Bioinformatics and statistical analysis were performed with the R programming language and public web tools. Our preliminary findings show a differential molecular signature involved in shaping the immune infiltrate in melanoma tumors sensitive and resistant to targeted therapies (BRAF and/or MEK inhibitors), and also in melanoma tumors responding and non-responding to anti PD-1 blockade. These molecules could be potential biomarkers of response as well as new actionable targets for the development of combination therapies. We also observed differences in the cellular composition of the immune infiltrate in melanoma tumors that are likely to be important determinants of both prognosis and response to treatment.

(1434) **OBTAINING AND CHARACTERIZING OF SINGLE DOMAIN ANTIBODIES DERIVED FROM CAMELIDS (NANOANTIBODIES OR VHH) AGAINST FOOT-AND-MOUTH DISEASE VIRUS FOR DIAGNOSTIC APPLICATION**

Joaquin Bozzo, Florencia Marchese, Nora Mattion, Vanina Grippo
CEVAN, Instituto de Ciencia y Tecnología Dr. César Milstein, CONICET.

Foot-and-Mouth Disease (FMD) is a viral disease of livestock with serious economic repercussions. Development of innovative diagnostic methods for the FMD control is of concern due to the susceptibility of species of economic interest. Camelids present heavy chain only antibodies (IgG 2 and 3), so the variable domain consists of a single domain (VHH or Nanoantibody). These antibodies represent a novel tool with unique characteristics conferring great potential in the development of new more sensitive diagnostic methods. For this reason, the present work aimed to obtain and preliminary characterize VHH specific against FMDV for its application in the diagnostic innovation.

Two llamas (*Lama glama*) were immunized with the strains O1/Campos, A24/Cruzeiro (A24), A/Arg/2001 (A2001) and C3/Indaial (C3). Humoral immune response (total IgG and subtype titers) was assessed throughout the immunization schedule obtaining high levels of heavy chain-only antibodies against the 4 serotypes by ELISA. Serum reactivity against viral proteins was confirmed in Western Blot. Two Nanoantibody libraries were constructed starting from llama peripheral blood and VHH against O1C strain were selected by Phage Display. Even more, 119 out of 182 selected clones recognized the 4 serotypes in ELISA. From these clones, 17 which showed very high reactivity in ELISA were selected for diversity analysis by enzymatic digestion. As a result, it was shown that 16 out of 17 clones presented different fingerprinting pattern.

In conclusion, two VHH libraries were constructed from immunized llama with the O1C, A24, A2001 and C3 strains. Both llamas had a high immune response and their sera were able to recognize the 4 FMDV serotypes. Furthermore, the two llamas had high levels of heavy chain only antibodies, mainly IgG3 subtype. At least 16 different cross-reactive Nanoantibodies were obtained against the 4 strains. Thus, these antibodies represent a potential tool for diagnostic innovation of FMDV.

(1451) **OPTIMIZATION OF THE PRODUCTION PROCESS OF AcrA-O157,
A RECOMBINANT GLYCOPROTEIN FOR THE SERODIAGNOSIS OF HEMOLYTIC UREMIC SYNDROME.**

Ana Josefina Caillava, Gastón Ezequiel Ortiz, Andrés Eduardo Ciocchini, Diego José Comerci
IIB-INTECH, UNSAM CONICET

Escherichia coli O157:H7 represents the most important etiological agent of Hemolytic Uremic Syndrome associated with Shiga toxin-producing *Escherichia coli* (STEC) worldwide. Recently, our group have developed a high-performance test for the serodiagnosis of human infection with *E. coli* O157 employing a new recombinant glycoprotein (AcrA-O157), consisting of the O157 polysaccharide attached to a carrier protein (AcrA), as antigen. Characterization and optimization of AcrA-O157 production process is important for increasing productivity and for scaling up. In this work, we evaluated AcrA-O157 production in different culture media and defined 2xYP as the optimal culture medium. In order to maximize the specific productivity of AcrA-O157, we analyzed the relationship between the specific product synthesis rate (qp) and the growth rate (μ). Exponential fed-batch cultures were designed using a pre-defined exponential feeding strategy based on the desired μ and the biomass yield. We analyzed glycosylation rate, product synthesis rate and production kinetics at three different specific growth rates: 0,32 h^{-1} (equal to μ_{max}), 0,21 h^{-1} and 0,14 h^{-1} by Western Blot and ELISA. We observed maximum glycosylation degree of AcrA at highest μ indicating that the glycosylation rate is affected by the specific growth rate. Specific rate of product formation was also influenced by specific growth rate, increasing 3-fold and 7,2-fold at 0,21 h^{-1} and 0,32 h^{-1}, respectively, when compared to 0,14 h^{-1}. Additionally, we observed a shorter lag phase to reach the maximal specific productivity when working at higher μ. Based on these results, we conclude that μ_{max} is the optimal specific growth rate allowing us to achieve the highest productivity with a shorter lag phase.

Keywords: optimization, recombinant glycoprotein, SUH serodiagnosis

(1511) **CONSTRUCTION OF IMMUNE VHH LIBRARIES AND SELECTION OF SPECIFIC NANOBODIES AGAINST HUMAN IGG4 FOR DIAGNOSTIC APPLICATION IN SYSTEMIC LUPUS ERYTHEMATOSUS**

Florencia Marchese, Joaquin Bozzo, Nora Mattion, Vanina Grippo
CEVAN, Instituto de Ciencia y Tecnología Dr. César Milstein, CONICET.

Systemic Lupus Erythematosus (SLE) is a chronic and inflammatory autoimmune disease. The prevalence of SLE in Argentina is 58.6 per 100 thousands inhabitants. Due to the heterogeneity of the clinical manifestations and the wide profile of autoantibodies developed by the affected individuals, it is a challenge to diagnose specifically the disease. On one hand, it has been reported a correlation between IgG4 levels and severity of the disease. For this reason, IgG4 has been proposed as a putative biomarker for SLE diagnosis. On the other hand, camelids present heavy chain only antibodies, so the variable domain consists of a single domain (called VHH or Nanoantibody). The use of VHH has revolutionized the field of monoclonal antibodies due to their unique and superior properties compared to conventional antibodies. They have a great potential for the development of more sensitive diagnosis methods. For this reason, our goal was to construct two VHH libraries and obtain specific nanobodies against human IgG4 for their application in SLE diagnosis.

In this work, two llamas were immunized with human IgG4 obtaining a high immune response measured by ELISA. Starting from llama peripheral blood, the heavy chain variable regions of conventional antibodies (VH) and only heavy chain antibodies (VHH) were amplified. In a Nested-PCR, only the VHH fragment were amplified and subsequently cloned in the pHEN4 phagemid vector. Then, TG1 *E. coli* bacteria were electroporated to obtain two Nanobody librar-

ies. Phages expressing VHH that specifically recognized IgG4 biomarker were selected by Phage Display methodology. Even more, reactivity of selected Nanobodies was confirmed by Phage-ELISA.

In conclusion, two immune VHH libraries were obtained with the expected size and high percentage of full length clones. Furthermore, specific Nanobodies against human IgG4 were selected by Phage display. Thus, these VHH constitutes an innovative tool for potential application in SLE diagnosis.

Keywords: Systemic Lupus Erythematosus (SLE), VHH, IgG4, Nanobody, Diagnosis.

(1562) **BOVINE TUBERCULOSIS, PRODUCTION OF MONOCLONAL ANTIBODIES AGAINST BOVINE IFN GAMMA USING A *IN SITU* METHOD OF SCREENING**

Luciana María Villafañe, Osvaldo Zabal, Fabiana Bigi, Marina Andrea Forrellad

Instituto De Biotecnología, CICVYA, INTA, Buenos Aires, Argentina

Bovine tuberculosis (TBB) is one of the major zoonotic diseases in our country that causes large economic losses. SENASA employs a control of TBB eradication based on the tuberculin skin test; however, several countries use an alternative and complementary indirect ELISA technique based on bovine IFN detection. Our objective is to obtain bovine anti-IFN monoclonal antibodies (MAb) which can be used for the development of a national ELISA test. Since one of the critical stages of obtaining MAb is the detection of positive clones between the generated hybridomas, two techniques were compared: serial dilution of the positive cells and *in situ* screening using nitrocellulose membranes pre-adsorbed with the antigen (Ag). For this, BALB/c mice were immunized with recombinant bovine IFN and after reaching a titer of 10^4, they were sacrificed, the spleen removed to obtain splenocytes and fused to the NS0 cells following Milstein method. The resulting hybridomas were cultured in selective medium and at 10 days after fusion a first screening by indirect ELISA was performed. They were expanded and then tested according to the *in situ* screening method described by Orii (2013) with modifications. For this, nitrocellulose discs pre-absorbed with bovine IFN were placed on the cells and incubated for 4 hours. After incubation, the discs were mixed with 5% milk TPBS buffer contained anti-mouse IgG conjugated to alkaline phosphatase detecting positive cells with BCIP/NBT substrates. Using as reference the location of the points on the discs, the cells which originated them were transferred to 96 wells plates for expansion and subsequently subcloning by limiting dilutions. 96% of the cells selected with *in situ* screening were positive for MAb production whereas only 3% were obtained using limiting dilution technique. The gain of positive clones was significant using the *in situ* method of screening. KEYWORDS: Bovine Tuberculosis – MAb – bovine IFN

(633) **PHYSICOCHEMICAL AND BIOLOGICAL CHARACTERIZATION OF THE RITUXIMAB BIOSIMILAR RTXM83**

Maria Laura Cerutti (1), Analia Pesce (2), Cedric Bes (3), Mauricio Seigelchifer (2)

(1) Fundación Instituto Leloir-IIBBA-CONICET; CRIP-IIB-UNSAM Buenos Aires, Argentina. (2) PharmADN, mAbxience Co., Buenos Aires, Argentina. (3) mAbxience Co., Madrid, España.

Biosimilars are biologic drugs designed to be similar to existing biopharmaceutical products for which patents have expired. Even though there are already approved Biosimilars in Europe and USA, the biosimilar manufacturing industry is also flourishing in emerging markets such as LatAm, Russia and Asia, where biosimilar adoption represents a strategic avenue to provide high quality and clinically effective medications at reduced cost. Rituximab is a chimeric monoclonal antibody approved for Non-Hodgkins lymphoma, chronic lymphocytic leukemia, and some autoimmune conditions. It is targeted against the pan-B-cell marker CD20 and exerts its therapeutic action through three different mechanisms of cell destruction: direct signaling of apoptosis, complement-dependent cytotoxicity and antibody-mediated cellular cytotoxicity. We herein present the development and physicochemical and functional characterization of the Rituximab biosimilar RTXM83. In accordance with the guidelines established by International Regulatory Agencies such as the EMA and the FDA, the critical quality attributes of RTXM83 were evaluated in a comparability exercise to its reference product (RP) using an orthogonal approach. Some of the methodologies employed in this study are: peptide mapping and MS analysis, CD spectroscopy, SDS-PAGE, SE HPLC and glycan and charge variants analysis by chromatography, SPR binding assays and cell-based potency bioassays. The results indicate that the primary and higher order protein structures as well the post-translational modifications and impurity profiles of RTXM83 are similar to the RP. RTXM83 also showed similarity to the RP in terms of ADCC, CDC and apoptosis potency and binding affinities to CD20, C1q and a complete panel of Fc Receptors. Overall, these data reveal that RTXM83 can mimic the described mechanisms of action of Rituximab and provide confidence that it will match the potency and safety of the reference product in ongoing clinical trials.

Ticagrelor (TICA) inhibits the P2Y12 receptor and interferes with cellular adenosine uptake. Increased adenosine levels during ischemia and reperfusion protect against ischemia-reperfusion injury. This work aims to prevent cardiovascular remodeling and ventricular arrhythmias with chronic administration of TICA in SHR rats fed with fructose to induce metabolic syndrome. We studied male rats from risk factor models: 1) WKY, normotensive control; 2) FFR, fructose-fed rat 10% (w/v) fructose solution during all six weeks; 3) SHR, spontaneously hypertensive rats; 4) FFHR fructose-fed hypertensive rats. These four groups were divided into TICA: (30 mg/kg intraesophageal for six weeks) or vehicle (n=8 each group). Metabolic variables and systolic blood pressure were compared at weeks six and before sacrifice at week twelve. Macroscopic and microscopic measurements evaluated cardiac remodeling. Langendorff-perfused hearts underwent 10 min of regional ischemia and assessed for reperfusion arrhythmias. Connexin-43 and PKC-epsilon expression were determined by western blot. The FFHR experimental model presented metabolic syndrome criteria and cardiac remodeling. Chronic treatment with TICA reduced ventricular fibrillation incidence in WKY, SHR and FFHR groups but failed to protect FFR. In all groups, TICA increased connexin 43. However, PKC-epsilon phosphorylated form of connexin 43 did not increase in FFR+TICA. We conclude that antiarrhythmic effects of TICA could be blunted in some risk factor models regarding connexin 43 phosphorylation by PKC. Further studies TICA effects on intercellular communication or hemichannel function of connexin 43 seem highly worthwhile.

Key words: ticagrelor, arrhythmias, connexin 43, PKC, metabolic syndrome

(583) **ASSOCIATION BETWEEN GENE EARLY B-CELL FACTOR 1 (EBF1) RS4704963 SNP AND CARDIOVASCULAR RISK FACTORS**

Alejandra Duarte (1), Mario B Principato (2), María Alejandra Von Wulffen (2), Natalia Ciampi (2), Rodolfo Kolliker Frers (3), Justo Carbajales (2), Rocío Castilla (3)

High blood pressure (HBP), obesity, smoking and type II diabetes

(DBT) are cardiovascular risk factors (CRFs) in which genetic susceptibility plays an important role.

Transcription factor early B-cell factor 1 (EBF1) is expressed in adipocytes and olfactory neuroepithelium, and participates in immune system development, adipogenesis and insulin resistance. The presence of the single nucleotid polymorphism (SNP) rs4704963: T<C in the EBF1 gene has been associated with early onset of coronary disease and a higher incidence of central obesity in patients suffering stress.

Our objective was to study the relationship between the presence of the SNP rs4704963 of EBF1 gene and the above-mentioned CRFs in patients with multiple CRFs with or without acute myocardial infarction (AMI).

To this end, 104 patients having two or more CRFs were evaluated. Characteristics of the population: mean age 59 years, 60.6% male, 63.5% with AMI, 36.5% with CRFs without AMI, 51% diabetic, 57.7% hypertensive and 59.6% smokers. Genotyping was performed on DNA obtained from blood samples of patients through nested PCR technique and subsequent sequencing. Statistical test CHI2 and logistic regression (OR) were done.

Results: The SNP rs4704963 was present in 16.3% patients in the heterozygous T/C and none in the homozygous T/T haplotype.

Considering the dominant genetic model, no correlation was detected between the SNP presence and AMI occurrence.

In our population, neither HBP, waist diameter nor DBT correlated with the development of AMI, although obesity increase measured by BMI ($p<0.05$) and smoking ($p<0.05$) did positively correlate.

The presence of the SNP did not correlate with an increase in BMI, waist diameter, DBT or HBP, but a significant correlation ($p<0.05$) was found with smoking.

Conclusion: The presence of SNP rs4704963: T<C in the EBF1 gene is not related to the development of obesity, DBT, and HBP, but it can be a predisposing factor for smoking.

Keywords: diabetes, obesity, gene EBF1, polimorfism, myocardial infarction.

(1224) **HIGH FAT DIET-INDUCED METABOLLICALLY OBESE AND NORMAL WEIGHT RABBIT MODEL SHOWS EARLY VASCULAR DYSFUNCTION. ROLE OF CYCLOOXYGENASE-2 IN NORMAL OXIDATIVE STATUS**

Gabriela Alarcon (1), Julieta Roco (1), Mirta Medina (2), Analia Medina (2), Susana Jerez (1, 2)
(1) CONICET, (2) UNT

Association between obesity and vascular dysfunction has been widely probed. However, mechanisms of vascular changes in individuals with normal weight and clinical characteristics of metabolic syndrome (MS) have not been described so far. The aim of the present work was to evaluate endothelial function and vascular reactivity in a metabolically obese and normal weight (MONW) rabbit model developed by feeding animals on a high fat diet (HFD). **Methods:** male rabbits were fed either regular diet (CD) or 18% fat in regular diet (HFD) by 6 weeks. **Results:** HFD induced glucose intolerance (CD:140±5 mg/dl vs HFD:163±4 mg/dl), increased fasting glucose (CD: 102±6 mg/dl v HFD: 126±5 mg/dl), triglycerides(CD: 112±6 mg/dl v HFD: 193±5 mg/dl), C reactive protein (CD: 5.1±0.9 mg/dl v HFD: 22±3 mg/dl), visceral abdominal fat (CD: 0.29±0.05 % vs HFD: 2.3±0.1 %) , TyG index (product of the fasting blood glucose and TG levels, CD: 8.27±0.22 vs HFD: 9.28±0.11) and decreased HDL-cholesterol (CD: 54±4 mg/dl vs HFD: 23±3 mg/dl) and plasma nitrites (CD: 1752±784 nmoles/l vs HFD: 324±109 nmoles/l). No differences were found in body weight, TBARS and Glutathione serum levels between the two diet groups. In aortic rings, isometric contractions measurement showed that HFD: a) reduced the acetylcholine relaxation, effect reversed by NS398 (cyclooygenase-2 inhibitor) and SC560, (cyclooxygenase-1 inhibitor); b) increased the contractile response to norepinephrine and KCl; c) improved the angiotensin II-potency, effect reversed by NS398 and SQ 29538 (TP receptor blocker). Immunohistochemistry and western blot showed cyclooxygenase-2 expression only in arteries from HFD rabbits. **Conclusions:** HFD induced vascular dysfunction in a model of MONW. Cyclooxygenase-2 up regulation may account for these functional alterations. Considering that normal oxidative status was found in our MONW model inflammatory process may account for the metabolic alterations in early stages of the MS.

(1088) **IL-6 REGULATES INSULIN RESISTANCE AND CARDIOVASCULAR DISEASE DURING *TRYPANOSOMA CRUZI* EXPERIMENTAL INFECTION**

Liliana Maria Sanmarco (1), Natalia Eberhardt (1), Nicolás Ponce (1), Gastón Bergero (1), Carlos Vigliano (2), Roxana Cano (1, 3), Pilar Aoki (1)
(1) Centro de Investigaciones en Bioquímica Clínica e Inmunología (CIBICI)-CONICET, (2) IMETTYB CONICET, Servicio de Anatomía Patológica, Hospital Universitario Fundación Favaloro, (3) Facultad de Ciencias Químicas, UA Área CS. AGR. ING. BIO Y S CONICET. Universidad Católica de Córdoba.

Oxidative stress generation is proposed as the common pathogenic factor mediating the appearance of insulin resistance while producing increased cardiovascular risk. We have recently reported a potent anti-oxidant effect of IL-6, so we hypothesize that IL-6 could be involved in insulin sensitivity and cardiovascular function during *T. cruzi* infection. We observed that infection induces increased frequency of nitric oxide (NO)-producing monocytes in peripheral blood from IL-6-deficient mice (KO) in comparison with C57BL/6 (WT) mice at all days post-infection (dpi) studied (0 dpi p=0.0301, 4 dpi p=0.0006, 14 dpi p=0.0007, 21 dpi p=0.0165). Among the metabolic parameters assayed in plasma, we observed increased glucose (p=0.0120) and insulin (p=0.0286) levels, with the consequent augmented HOMA-IR index (p=0.0197) at 14 dpi in KO mice compared to WT mice. These results suggest that IL-6-deficiency induces acute insulin resistance. The fatty acid transporter and scavenger receptor CD36 is implicated in the pathogenesis of insulin resistance and associated cardiovascular complications. Considering that KO mice showed higher frequency of CD36+ circulating monocytes (p=0.0045) in comparison with WT mice at 14 dpi, we analyzed if IL-6 could be regulating insulin sensitivity by modulating this scavenger receptor. IL-6 stimulation of *T. cruzi*-infected bone marrow-derived macrophages (BMDM) diminished the frequency of CD36+ BMDM and increased the percentage of insulin receptor+ BMDM compared to unstimulated-infected cells. Considering that cardiovascular dysfunction is a complication of metabolic syndrome, we observed that KO mice showed increased creatin-kinase (CK) MB/total CK ratio (p=0.0016) and creatinine plasmatic levels (p=0.0003), biomarkers of cardiac and kidney damage respectively, in comparison with WT mice. Altogether, the data obtained show that IL-6 protects mice from *T. cruzi*-induced oxidative stress and the consequent insulin resistance and kidney dysfunction.

Keywords: IL-6, cardiovascular disease, oxidative stress, insulin resistance, CD36.

(1176) **NEBIVOLOL IN COMBINATION WITH TEMPOL IMPROVES METABOLIC AND HEMODINAMIC PARAMETERS IN A MODEL OF METABOLIC SYNDROME.**

Yanina Alejandra Santander Plantamura (1), Camila Boquete (1), Miguel Allo (1), Luciano Parola (1), Julieta Del Mauro (1), Andrea Carranza (2), Ariel Polizio (2), Susana Gorzalczany (1), Diego Chiappetta (3), Martin Donato (4), Christian Höcht (1), Carlos Taira (1)

The metabolic syndrome (MS) is a constellation of metabolic abnormalities such as glucose intolerance, hipertrigliceridemia, hypertension and inflammation that predispose to type 2 diabetes and cardiovascular diseases.

The therapeutic arsenal of hypertension is composed by several pharmacology groups. Beta blockers have a lower benefit in the treatment of essential hypertension compared with other drugs. However in the last years, have been arouse the third generation beta blockers, like nebivolol, which enhances of NO dependent va-

sodilatation.

Tempol is an antioxidant that mimics the action of the superoxide dismutase enzyme, that catalyses the conversion of O2˙- into H2O2, and the consequent reduction of blood pressure.

The aim of this work was to evaluate the effects of nebivolol, alone or combined with tempol, on systolic blood pressure (SBP), the echocardiography and metabolic parameters in a model of metabolic syndrome.

Male Sprague Dawley rats (250-300g) with or without fructose (F) (10% w/v) in tap water during 12 weeks, were distributed in 4 groups (n=6): control, Nebivolol (15 mg/kg/day/ i.g.), Tempol (60 mg/Kg/day/ i.g) and nebivolol + tempol. All groups were evaluated for indirect SBP by tail-cuff method, echocardiography Doppler and oral glucose Tolerance test (OGTT).

In comparison with normotensive rats, F overloaded rats showed an increase of indirect SBP (mmHg, C: 120±2 vs F: 138±4, $p<0.05$). Treatment with nebivolol, alone (116±1.20 mmHg) or combined with tempol (118±2.8 mmHg), was able to reduce SBP when compared with F rats. The Isovolumetric relaxation time and echocardiography hypertrophy parameters were improved with the combinated therapy. Also the OGTT test was improved in the combined treatment.

In the experimental model of MS induced by F, chronic treatment with nebivolol was able to reduce SBP. The combination of nebivolol with the antioxidant tempol improves ventricular left hypertrophy, diastolic function and the OGTT in the fructose group.

(1121) **NITRIC OXIDE AS SIGNALING MOLECULE INVOLVED IN EARLY STAGES OF CARDIAC MITOCHONDRIAL DYSFUNCTION IN DIABETES MELLITUS**

Ivana Agustina Rukavina Mikusic (1, 2), Silvina Sonia Bombicino (1), Laura Beatriz Valdez (1, 2)
(1) University of Buenos Aires, School of Pharmacy and Biochemistry, Physical Chemistry Division; Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), University of Buenos Aires, (2) Institute of Biochemistry and Molecular Medicine (IBIMOL). Buenos Aires, Argentina

Previous results from our laboratory have shown that sustained hyperglycemia (28 days) leads to heart mitochondrial dysfunction with increases in H_2O_2 and NO steady-state concentrations. This mitochondrial impairment was detected in the absence of heart hypertrophy and of changes in resting cardiac performance, suggesting that mitochondrial dysfunction precedes the onset of diabetic cardiac failure. In this scenario, H_2O_2 and NO could be molecules involved in mitochondrion-cytosol signaling. The aim was to study the role of NO and H_2O_2 in early stages of the mitochondrial dysfunction, in an experimental model of Type I Diabetes Mellitus (DM). Diabetes was induced by a single dose of Streptozoticin (60 mg/kg, ip.) in male Wistar rats. Glycemia was determined 72 hours after injection (C:117±6 mg/dl; DM:502±27 mg/dl). The animals were sacrificed at day 10 and heart mitochondrial fraction was isolated. State 3 respiration sustained by malate-glutamate and by succinate was 18% and 13% lower in diabetic than in control rats. Because of resting mitochondrial O_2 consumption rates did not modify, respiratory control ratios mainly declined when malate-glutamate was used as substrate. These results agree with complexes I-III and II-III activities that were lower (15 and 11%) in diabetic than in control animals. However, no difference was observed in complex IV activity. Moreover, mitochondrial GSSG/GSH ratio was higher (25%) in diabetic animals suggesting an imbalance in cellular redox state. Preliminary results have shown that while mitochondrial NO production rate was 18% higher in diabetic rats, H_2O_2 generation did not modify. These results show an early mitochondrial dysfunction, after 7 days of sustained hyperglycemia, accompanied by an increase in NO generation suggesting that this molecule could be involved in the triggering of heart mitochondrial biogenesis in an initial phase of DM.

The cardiometabolic syndrome (CMS) is a constellation of interrelated risk factors of metabolic origins that together promote the increased risk of cardiovascular disease (CVD). Central obesity with the associated CMS components promotes proinflammatory and prothrombotic states. The aim of the present work was study whether platelet and fibrin network-morphology or coagulation profiles was altered in a rabbit model of CMS. Male rabbits were fed either a control diet (CD) or atherogenic high fat diet (18 % fat and 1 % cholesterol, HFD-HC) during 6 weeks. Scanning electron microscopy was used to study platelet- and fibrin network-morphology by preparing platelet-rich plasma (PRP). Ten µl of PRP was used to study platelet morphology and 10 µl of PRP was mixed with 5 µl of bovine thrombin (2,7UI/ml) to study fibrin network morphology. Activated Partial Thromboplastin Time (APTT), thombin time and platelets count were performed. Platelets of the CD appeared spherical with few pseudopodia present while the platelets of the CMS presented with numerous pseudopodia and spreading, indicating activation. The fibrin networks of the CD consist of thick and thin fibers that form an organized network of fibers. The fibrin networks of the CMS appeared less organized with less taut fibers. Fibrin fiber thickness was found to be significantly increased in the CMS group (p-value <0.05) when compared to CD. The thicker fibers formed irregular networks with thick masses of fibrin fibers. The hemostatic profiles of the CMS did not differ significantly (p-value>0.05) from the CD, indicating a normal functioning coagulation cascade. The findings indicate that premature activation of platelets (as a result of chronic inflammation) that in turn causes altered fibrin formation but not alterations in the coagulation cascade may account for the prothrombotic status in the CMS.

Stevia rebaudiana bertoni, an herbaceous plant widely distributed and used in Paraguay and Brazil for its sweetener character, has several medicinal properties including antitumor, antihypertensive and anti-inflammatory actions. The aim of the present study was to investigate the cardioprotection exerted by oral stevioside (E, 168 mg/kg for 15 days), a major component of stevia, and its relationship with the activation of protein kinase B (PKB/Akt) in Langendorff perfused rat hearts subjected to ischemia (I)-reperfusion (RP). Hearts from female Wistar rats (200-250g) fed ad libitum were used. Wortmannin (W, 100nM), PI3K/Akt inhibitor was added 15 min before I. The contractility was evaluated by determining the left ventricular developed pressure (LVDP), rate-pressure product (RPP) was determined by multiplying heart rate (HR) by LVDP, peak rate of contraction and peak rate of relaxation (±dP/dt), and the left ventricular end-diastolic pressure was measured (LVEDP). The creatine kinase (CK) release was determined in the coronary effluent during the first 10 min of RP and the myocardial infarct size (MIS) was determined by staining with triphenyltetrazolium chloride (TTC) dissolved in phosphate buffer. ANOVA, n=8/group. E improved postischemic recovery and W annuled the cardioprotective actions mediated by E (at 30 min RP RPP (%): C 55.5±8.8, C+W 52.0±5.1, E 87.2±14.8*, E+W 57.0±14.8; *p<0.05 vs C, W, E+W). These results were accompanied with similar changes in ±dP/dt. LVEDP developed lower values in the E group (LVEDP (%) at 10 min of RP: C 15.5±2.0, C+W 29.0±2.2, E 2.2±0.9*, E+W 24.0±3.6; *p<0.05). E decreased CK release and infarct size (CK (UI/g wet weight) C 40.6±3.5, C+W 47.0±4.7, E 24.8±3.2*, E+W 33.0±3.8; MIS (%) C 62.1±1.5, C+W

68.2±2.1, E 41.6±3.5*; E+W 58,2±2.1; *p<0.05 vs C, W, E+W). These results suggest that oral administration of E presents cardioprotective effects that could be partly mediated by Akt activation.

Keywords: stevioside, ischemia, reperfusion.

(1641) **TABAQUISM AND CARDIOMYOPHATIES. EFFECTS OF TOBACCO CONSUMPTION ON CARDIAC CALCIUM HANDLING IN *Drosophila melanogaster***

Dario Balcazar (1), Nadia Paronzini Hernandez (1), Manuela Santalla (1,2), Carlos Alfredo Valverde (1), Alicia Mattiazzi (1), Paola Ferrero (1,2)
(1) CIC. (2) UNNOBA.

Tabaquism is a chronic disease caused by nicotine addiction, being responsible for about 40.000 deaths/ year in Argentine. Cardiovascular effects include coronary heart disease, acute myocardial infarction and congenital cardiomyopathy. The fruit fly *Drosophila melanogaster* is a well-known model used to study several human diseases and addictions. The possibility to edit its genome, to produce transgenic lines and to study the interaction between genes and the environment, make this organism an alternative to study a possible relationship between genes and tobacco effects. We developed an experimental approach of “chronic consuming-cigarette” flies simulating active human smoking. We compared the cardiac function of smoking flies (S) vs. non-smoking controls (C). Tobacco increased heart rate (beats/min: S: 155.5 ±14.6 n=6, C: 105.8±6.9 n=12), reduced Ca2+ transient amplitude (arbitrary units of fluorescence: S: 1.27±0.2 n=10, C: 0.25±0.05 n=7), time of to peak contraction (TTP S: 0.16±0.01 sec n=12, S: 0.12±0.01 sec n= 5) and relaxation time (t1/2 S: 0.12±0.01 sec n=12, C: 0.07±0.02 sec n=5). Similar results were obtained with nicotine alone, in semi-intac preparation. Together, our evidences suggest that nicotine is the principal component of tobacco that induces cardiac changes in the fly’s adult heart.

Current experiments are exploring receptors and signaling pathways involved in nicotine action on heart function. *D. melanogaster* presents glutamatergic and beta like-adrenergic receptors, associated to nervous terminals reaching the heart. Moreover, nicotinic receptors (nAChR) could be present in cardiac *Drosophila* muscles. We detected nAChR1 in adult total extract of protein of *D. melanogaster* using the antibody against human nAChR1. Assays in course are orientated to determinate the contribution of these three types of receptor activation to the nicotine effects on cardiac activity.

Key words: Tabaquism; Nicotine; Drosophila melanogaster; Cardiac alterations; Nicotinic receptors.

(280) **DIETS ENRICHED IN OLIVE OIL REGULATES THE EXPRESSION OF PPAR TARGET GENES IN THE FETAL LIVER IN A RAT MODEL OF GESTATIONAL DIABETES MELLITUS (GDM) INDUCED BY INTRAUTERINE PROGRAMMING.**

Daiana Fornes, Veronica White, Evangelina Capobianco, Alicia Jawerbaum
CEFyBO - Facultad de Medicina - UBA

In a rat model of GDM induced by intrauterine programming, we previously found sex-dependent alterations in PPAR target enzymes involved in lipid accretion or oxidation as well as increased prooxidant/proinflammatory markers in the fetal liver. **Aim**: To address whether maternal diets enriched in olive oil prevent the alterations in lipid metabolizing enzymes in the fetal liver and whether there are changes in the expression of nuclear factor erythroid-derived-2 like 2 (NRF2), a PPAR target gene relevant in the regulation of antioxidant enzymes. **Methods**: Pregestational diabetic rats (F0) were obtained by neonatal streptozotocin administration. F0 rats were mated with healthy males. No treatments were performed in the F1 offspring until the 3rd month of age, when the rats were mated with healthy males. During F1 pregnancies the rats were fed with a standard diet supplemented or not with 6% olive oil. Maternal metabolic parameters and the mRNA levels of the genes codifying fatty acid synthase (FAS), acyl CoA oxidase (ACO) and NRF2 in the fetal liver were evaluated (by RT-PCR) on day 21 of pregnancy. **Results**: Maternal olive oil treatment did not prevent maternal hyperglycemia but reduced maternal triglyceridemia (21%, p<0.05). The increased FAS mRNA levels in the liver of male fetuses of GDM rats were prevented with the olive oil treatment (92% reduction, p<0.001). ACO levels, increased in the liver of female fetuses of GDM rats, were reduced with the olive oil treatment (95% reduction, p<0.001). Moreover, NRF2 expression was reduced in the liver of female fetuses of GDM rats fed with standard diet compared to controls (64% reduction, p<0.01), an alteration prevented by the olive oil treatment (100% increase, p<0.05). **Conclusion:** Maternal olive oil treatment in the rats that develop GDM, do not prevent GDM induction, but regulate fetal liver enzymes involved in lipid metabolism and antioxidant pathways, probably improving liver function in the offspring´s later life.

Universidad de Buenos Aires. Argentina.

Preeclamptic placentas are characterized by an abnormal trophoblastic invasion of the spiral arteries resulting in an inadequate utero-placental blood flow. Consequently, an intermittent perfusion is established which leads to an ischemia/reperfusion injury in the syncytiotrophoblast. Fluctuations in O_2 tensions may increase the generation of reactive nitrogen species (RNS) by promoting the formation of peroxynitrite (ONOO-) which could damage lipids, proteins and DNA. Recently, we reported that placental explants exposed to hypoxia/reoxygenation showed an overexpression of AQP9 with a lack of functionality similar to that observed in preeclamptic placentas. However, the mechanisms by which it occurs are still unknown.

Our aim was to evaluate the effect of nitrosative stress mediated by $ONOO^-$ on AQP9 expression. This study was approved by the ethics committee of the Hospital Nacional Dr. Prof. A. Posadas. Placental explants were cultured in complete DMEM-F12. $MgSO_4$ was added to neutralize the effect of ONOO-, since it is used extensively for *prevention* and *treatment* of eclampsia, associated with a reduction in maternal and fetal morbidity. Lipid peroxidation (TBARS) was determined. Expressions of superoxide dismutase 1 (SOD-1), as a measure of the antioxidant enzyme defense system, and AQP9 were also studied.

In the presence of 100 μM of $ONOO^-$, AQP9 expression significantly increased 75.42 ± 0.75% compared to control (*n=7; p<0.05*). In this condition, TBARS increased 3-fold (*n=5, p<0,002*), while SOD-1 showed a 70.35 ± 16.51% decrease (*n=5, p <0.02*). The addition of $MgSO_4$ restored SOD-1(*n=3, p<0.02*) and AQP9 (*n=5, p<0.05*) expressions to control levels.

Our results show that the production of RNS dramatically increases AQP9 expression. However, further studies are required to elucidate whether the high nitric oxide levels could nitrate the tyrosine residues of AQP9, resulting in a non-functional protein and the implications in the pathogenesis of preeclampsia.

Keywords: AQP9, trophoblast, human placenta, nitrosative stress.

(1823) **EFFECT OF RESVERATROL ON ACTIVE MITOCHONDRIA AND LIPID PEROXIDATION OF VITRIFIED BOVINE EMBRYOS**

Sergio Morado (1), Stephania Madrid (2), Rodrigo Urrego (3), Albeiro López-Herrera (2), Giovanni Restrepo (4), Julián Echeverri (2), Pablo Cetica (5)

(5) Unidad Ejecutora de Investigaciones en Producción Animal, UBA-CONICET.

Despite being a new method for embryo cryopreservation, vitrification has been reported to increase reactive oxygen species (ROS) production and to diminish reduced glutathione content leading to deleterious effects on cells. To prevent oxidative damage, several antioxidants have been added to vitrification media. The aim of this study was to determine the effect of resveratrol on active mitochondria and lipid peroxidation of vitrified bovine embryos. Cumulus-oocyte complexes were cultured in medium 199 with the addition of fetal calf serum and gonadotropins at 39°C, 5% CO_2 in humidified air for 22h and then co-incubated with a suspension of $2x10^6$ motile spermatozoa/ml for 20h in IVF-mSOF. Then, presumptive zygotes were transferred to IVC-mSOF medium with or without the addition of 0.5μM resveratrol. At day 7, blastocysts were vitrified by a minimum volume method in the presence or absence of 0.5μM resveratrol. A group of non-vitrified blastocysts was used as control. Active mitochondria and superoxide anion ($O_2^{\cdot-}$) production were determined in the control and in different groups of vitrified blastocysts by Mitotracker Green FM/MitoSOX Red dual stain, while lipid peroxidation was determined by Bodipy. Blastocysts subjected to vitrification/warming presented higher active mitochondria and $O_2^{\cdot-}$ production than fresh blastocysts (P<0.05). The addition of resveratrol to IVC or vitrification medium reduced the increase in active mitochondria but not the increase in $O_2^{\cdot-}$ production (P<0.05) compared to blastocysts cultivated in non-suplemented IVC and in vitrification media. However, lipid peroxidation presented no significant changes in any case. In conclusion, these results might suggest that resveratrol would be scavenging other ROS during the propagation phase but not in the initiation phase, thus explaining its lack of effect on $O_2^{\cdot-}$ levels produced in vitrification/warming.

Keywords: resveratrol, vitrification, bovine embryos, ROS, superoxide anion.

(328) **MATERNAL OVERWEIGHT ALTERS THE SEXUAL MATURATION IN MALE OFFSPRING BY MODIFYING THE TESTICULAR HISTOLOGY AND TESTOSTERONE LEVELS**

Rocio Alejandra Galarza, Eric Alejandro Rhon-Calderón, Marianne Bizzozzero, Santiago Condemi, Analía Elizabeth Cortez, Victoria Lux-Lantos, Alicia Graciela Faletti
CONICET - CEFYBO, Facultad de Medicina, Buenos Aires, Argentina. UBA, Facultad de Medicina, Buenos Aires, Argentina.

An appropriate maternal body weight is needed for a normal fetal programming. Previous studies showed that maternal overweight affects the size and body weight, ano-genital distance, sperm count and morphology of the germ cells. Now, we studied whether the maternal overweight affects the testicular morphology and the levels of testosterone. To this end, male offspring from rats fed with standard (OSD) or cafeteria (OCD) diet, with high lipid content, were used. Considering the percentage of maternal overweight, the OCD were divided into two groups: offspring from rats with 25% and higher than 35% of overweight (OCD25 and OCD35, respectively). Offspring always were fed with standard diet and were euthanized at 60 days of age to obtain testes and blood serum. Seminiferous tubular diameter (STD), thickness of the seminiferous epithelium (SE) and tubular lumen diameter (TLD), expressed in μm, and the serum levels of testosterone, expressed in ng/ml, were examined. All data are expressed as mean±SEM and statistical analysis was performed by one-way ANOVA with Dunnett´s multiple comparison test or Kruskal-Wallis test with Dunn´s multiple comparison test. Compared with OSD (STD: 59±2, SE: 15±1), both OCD groups exhibited decrease in STD and SE, although these changes were only significant for OCD35 (STD: 41±4; P<0.001; SE: 8±1, P<0.01). Likewise, OCD35 showed higher testosterone levels (5.2±0.6, P<0.05) than OSD (2.7±0.3). No significant difference was found in that of OCD25 group. In conclusion, our results suggest that an intrauterine environment with high fat content may alter the reproductive ability of the male offspring, at least in part, altering the morphology of the testes and testosterone levels, likely as a result of altering the organogenesis.

Keywords: Overweight, cafeteria diet, testis morphology, testosterone.

(1125) **EFFICIENCY OF EMBRYO TRANSFER IN SHEEP UNDER DIFFERENT NUTRITIONAL STATUS OF DONOR AND RECIPIENT EWES**

María Macarena Bruno Galarraga (1), Marcela Cueto (1), Jimena Fernandez (1), Alejandro Gibbons (1), Rodolfo Luzbel de la Sota (2), Isabel Lacau (3)
(1) INTA EEA BARILOCHE, (2) Facultad de Ciencias Veterinarias-UNLP, (3) IBYME-CONICET

The objective of this study was to evaluate the effect of the nutritional status of embryo donors and recipients on embryo survival after direct transfer of embryos in sheep. The experimental study was carried out at the Reproduction Laboratory Facilities of INTA Bariloche. A total of 36 donor and 75 recipient Merino ewes received either 1.5 (S, Supplemented) or 0.5 (R, Restricted) times daily maintenance requirements (S donors n = 19, R donors n = 17, S recipients n = 36, R recipients n = 39), from the beginning of the estrus synchronization treatment until day 30 post estrus. On day 7 post estrus, one transferable embryo of donor females S or R was transferred into a recipient female S or R, defining the following groups: SS (n = 11), SR (n = 11), RS (n = 25) and RR (n = 28). The concentration of progesterone and metabolic hormones in donor and recipient ewes was determined according to nutritional status. The pregnancy rate on day 17 of gestation was similar between groups (73, 45, 72 and 64% for SS, SR, RS and RR, respectively; P > 0.1). However, embryo losses between days 17 and 35 of gestation were higher in the SR group (18%) than in the other three groups (9, 8 and 7% for SS, RS and RR, respectively; P < 0.1). Moreover, pregnancy rate on day 35 of gestation was lower in the SR group (27%) compared to the other groups (64, 64 and 57% for SS, RS and RR, respectively; P < 0.1). Donors and recipients under nutritional restriction had lower concentrations of IGF-1 (P < 0.01). In conclusion, failure to establish and maintain pregnancy may be related to an asynchrony between an unfavorable uterine environment in restricted recipient ewes and embryos produced by donors in a high nutritional condition.

Keywords: embryo losses, undernutrition, embryo transfer, sheep

(184) **FOXO1 TARGET GENES ARE ALTERED IN THE HEART OF THE OFFSPRING FROM DIABETIC RATS**

Hugo Sato, Sabrina Roberti, Alicia Jawerbaum, Romina Higa
CEFyBO-CONICET-UBA

Cardiovascular alterations in the adult can be developmentally programmed by maternal diabetes. FoxO1 participates in cellular oxidative homeostasis, metabolism and survival of cardiomyocites and its overactivation is related to cardiac dysfunction in diabetes. We have previously found increased FoxO1 levels in the offspring's heart from diabetic rats. FoxO1 activation can be inhibited by serum glucocorticoid kinase 1 (sgk1) phosphorylation that induces FoxO1 nuclear exportation. Connective tissue growth factor (CTGF, regulates fibrosis) and MMP2 (related to inflammatory processes when it is in excess) are FoxO1 target genes. Our **objective** is to evaluate serum markers of heart damage, mRNA levels of CTGF and MMP2 and phosphorylation status of sgk1 in the offspring's heart from control and diabetic rats. **Methodology**: Pregestational diabetic rats were obtained by neonatal streptozotocin administration and were mated with healthy males. Adult male offspring from control and diabetic rats were evaluated. Serum levels of lactate dehydrogenase (LDH) and myocardium creatine kinase (CK-MB) were determined by a commercial kit. In the heart, CTGF and MMP2 mRNA levels were evaluated by qPCR and phosphorylation status of sgk1 by western blot. **Results**: LDH and CK-MB, serum markers of heart damage, were found increased in diabetic offspring compared to

control (1.8 and 1.5 fold, p<0.05). mRNA levels of CTGF and MMP2 were increased (2.8 and 2.4 fold, p<0.05 and p<0.01 respectively) and Sgk1 phosphorylation status and ratio of phospho-sgk1/total sgk1 were decreased (p<0.05) in the heart of diabetic offspring compared to controls. **Conclusion:** The increased mRNA levels of FoxO1 target genes involved in profibrotic and proinflammatory processes are probably related with the increased levels of active FoxO1. These alterations could be involved in the increased levels of serum markers of heart damage found in male offspring from diabetic rats.

(1694) **DIFFERENTIAL GENE EXPRESSION AND HORMONAL REGULATION OF BONE MORPHOGENETIC PROTEIN INHIBITORS IN BOVINE OVIDUCT EPITHELIAL CELLS**

Elina Vanesa Garcia (1,2), María Emilia Oliva (2), Pablo Alberto Valdecantos (2), Dora Cristina Miceli (1,2), Antonio Daniel Barrera (1,2)
(1) INSIBIO (CONICET). (2) Instituto de Biología, Facultad de Bioquímica, Química y Farmacia, UNT.

Bone morphogenetic proteins (BMPs) play important roles in mammalian reproduction and female fertility. Previous studies have demonstrated that BMP ligands and receptors are expressed in an anatomically and temporally regulated fashion in the bovine oviduct. However, the molecular mechanisms that regulate BMP signaling in the oviductal context are still unknown. The present study aims to explore the regulatory context of BMP signaling in the bovine oviduct by focusing attention on their negative modulators. For this purpose, the mRNA expression of five antagonists of the BMP signaling pathway (*FST*, *BAMBI*, *NOG*, *CHRD* and *SOSTDC1*) were evaluated by RT-qPCR in bovine oviduct epithelial cells (BOECs) obtained from ampulla and isthmus at different stages of the estrous cycle. In addition, to evaluate if the expression of these genes respond to hormonal stimulation, cell suspension cultures of BOECs derived from both anatomical regions were stimulated with estradiol-17β (0.1, 1 and 10 nM) or progesterone (1, 10 and 100 nM) and analyzed by RT-qPCR. The expression of *FST*, *BAMBI*, *NOG*, *CHRD* and *SOSTDC1* was detected in BOECs from ampulla and isthmus during the estrous cycle. Except for *NOG*, regional and temporal differences were observed in the expression patterns of the genes analyzed. Particularly, higher mRNA levels were observed for *FST* in ampulla (P<0.001) and for *BAMBI* in isthmus (P<0.05) during the luteal phase. In the case of *CHRD* and *SOSTDC1*, a similar regulation pattern to *FST* was observed, but anatomical differences were statistically less significant (P<0.05). Under *in vitro* culture conditions, mRNA levels of *FST* and *BAMBI* increased in response to progesterone treatment while estrogen (10 nM) tended to suppress their expression. The region specific and cycle dependent expression differences together with the susceptibility to steroid hormones provide evidence to suggest a functional importance of BMP inhibitors in the regulation of oviductal physiology.

Adequate trophoblast (Tb) metabolism is crucial to allow nutrients transport from the mother to the fetus required for fetal growth and development. A dysregulation of this process may cause inappropriate fetal growth inducing Intrauterine Growth Restriction among other complications. Glucose is the main energy substrate for the placenta and the fetus and its transfer depends on maternal levels, placental glucose metabolism and facilitated transport through GLUT carrier proteins. GLUT1 appears to be one of the primary transporters of the placenta and is found at both maternal and fetal-facing Tb membrane. The vasoactive intestinal peptide (VIP) is a pleiotropic neuropeptide that was shown to inhibit glucose oxidation in rat enterocytes. We have previously demonstrated that VIP is synthesized by human Tb cells having autocrine and paracrine effects on these cells and favors Tb cell migration and invasion. Objectives: to study the role of VIP in the regulation of glucose uptake in Tb cells, placenta weight and fetal growth. Methods: we used two human Tb cell lines, Swan-71/BeWo, and implantation sites of C57BL/6 WT females mated to VIP-/- or WT males. Swan-71 VIP knocking-down was carried out using a VIP siRNA. GLUT1 and mTOR expression were evaluated by qRT-PCR and glucose uptake by flow cytometry using the fluorescent analogue 2-NBDG. Results: VIP induced glucose uptake in Tb cells through mTOR activation. An increase of GLUT1 and mTOR expression in siVIP vs. scramble transfected Tb cells and a dysregulation of glucose uptake were observed. On the other hand, VIP deficient embryos at day 14,5 showed reduced weight (WTxWT vs. WTxKO, p<0.001) without changes in placenta weight. An increased expression of GLUT1 and mTOR was observed in placenta from VIP WTxKO mice. Conclusion: Results of these *in vitro* and *in vivo* models are consistent with a role of VIP as a local factor modulating glucose uptake by the placenta and support its relevance in fetal growth.

The syncytiotrophoblast (STB) form a multinucleated layer that is maintained and regenerated by the fusion of underlying cytotrophoblast cells (CTBs). This structure is responsible for specialized functions of the human placenta and disturbance in this process may result in pregnancy-associated diseases such as preeclampsia and intrauterine growth restriction. Hypoxia modifies human placental villous syncytialization, however these mechanisms remains unknown. Previously we demonstrated that hypoxia inducible factor-1 alpha (HIF-1α) deregulated the endocannabinoid system (ES) in human placenta. In the present study, we investigated if HIF-1 and ES perform pivotal roles in trophoblast syncytialization.

BeWo cell line was cultured with 100μM forskolin (FSK) to induce cell fusion. CTB (BeWo) and STB (BeWo + FSK) cells were treated with and without cobalt chloride ($CoCl_2$), a hypoxia-mimetic agent that stabilizes (HIF-1α); or R-(+)-Methanandamide (Met-AEA), a stable anandamide analogous. Cell viability was evaluated by MTT assay. Markers for trophoblast syncytialization: syncytin-1 and glial cells missing-1 (GCM-1), were analyzed by western blot and RT-PCR. The location of the E-cadherin was studied by immunocytochemistry.

Incubation with $CoCl_2$ and Met-AEA significantly reduced cell viability (p<0,05; n=5). Treatment with 100μM $CoCl_2$ significantly increased HIF-1α protein levels (p<0,01; n=4). Forskolin-induced cell fusion identified by increased levels of GCM-1 mRNA and syncytin-1 protein expression was reversibly suppressed with $CoCl_2$ and Met-AEA treatment (p<0,05; n=5). Localization of E-cadherin confirmed that forskolin induced cell fusion. In the presence of $CoCl_2$ there was a significant decrease in BeWo cells fusion rate compared to forskolin treatment only.

The above results suggest that increased levels of HIF-1 may disturb trophoblast syncytialization and that endocannabinoids could play an important role in this critical process of human placenta.

Keywords: Trophoblast, HIF-1, Syncytialization, Endocannabinoids.

(761) **EFFECTS OF DEHYDROEPIANDROSTERONE ON THE UTERINE STROMA OF PERIPUBERTAL RATS**

Gisela Soledad Bracho (1), Laura Kass (1), Gabriela A. Altamirano (1), Mónica Muñoz-de-Toro (1), Enrique H. Luque (1), Verónica L. Bosquiazzo (1)
(1) INTITUTO DE SALUD Y AMBIENTE DEL LITORAL (CONICET-FBCB).

In a previous study we have shown an increase of the subepithelial stroma and myometrium thickness associated with a decrease in cell density in the uterus of hyperandrogenized rats. Here, we investigate aquaporin (AQP) expression, collagen content and cell proliferation of the uterine subepithelial stroma and myometrium in androgenized peripubertal rats. Wistar rats were injected sc with sesame oil (control group) or dehydroepiandrosterone (DHEA) 6 mg/100 g body weight from postnatal day 21 for 20 consecutive days to induce hyperandrogenism. Before sacrifice, the animals received an ip injection of Bromodeoxyuridine (BrdU, 6 mg/100 g body weight). One uterine horn was frozen in liquid nitrogen and used to evaluate the mRNA expression of AQP1 to 9 by quantitative real-time PCR. The other uterine horn was fixed in 10% buffered formalin and embedded in paraffin for histological studies. Collagen content was measured as integrated optical density (IOD) using picrosirius red staining and polarization microscopy. Cell proliferation was evaluated by determining BrdU incorporation by immunohistochemistry. The uterus of control rats expressed AQPs 1-5 and 7-9. In the DHEA group, AQP3 and 8 expressions were increased while AQP7 expression was decreased, compared to controls rats. Collagen content was increased in both the subepithelial stroma (control:1392±251 vs DHEA:4055±341; $p<0.05$) and myometrium (control:691±92 vs DHEA:2764±128; $p<0.05$) of DHEA-treated rats. Cell proliferation was decreased only in subepithelial stroma of DHEA-treated animals (control:7.3±2.4% vs DHEA:1.5±0.4 %; $p<0.05$). The results suggest that DHEA modifies the water content and the extracellular matrix of the uterus evidenced by changes in AQPs expression and collagen content. These results, together with a lower cell proliferation index may explain the increase in thickness and the decrease in cell density observed in the uterine subepithelial stroma and myometrium of hyperandrogenized animals.

(1008) **BONE ACTIONS OF THE FORGOTTEN ESTROGEN, ESTRONE**

María Carla Crescitelli, María Belén Rauschemberger, Virginia Massheimer
Instituto de Ciencias Biológicas y Biomédicas del Sur (INBIOSUR), Departamento de Biología Bioquímica y Farmacia, Universidad Nacional del Sur (UNS)-CONICET, Bahía Blanca, Argentina

Estrogens play an important role in bone remodeling. Although estradiol action has been the subject of intensive investigation, little is known about the contribution of the other major endogenous estrogen, estrone (E1). The aim of this work was to evaluate the effect of E1 on bone cells, particularly the modulation of osteoblasts (OB) maturation. Murine calvarial pre-OB were cultured for 3-15 days and exposed to E1 (10^{-8} – 10^{-10}M) in the last 48h. OB characterization was performed by the measurement of bone markers, using RT-PCR technique. mRNA levels for BMP-2 and Runx-2 were detected in all time of culture (3-15 days). Indeed the expression of both types of ER (α andβ) was also detected. In 15 days OB culture, E1 significantly increased cell proliferation (0,68±0,09 vs 0,49±0,09, E1 vs C, $p<0,001$ in MTT assay). These results were confirmed by cell counting (41% above C, $p<0,05$). Since mature OB exhibited high level of alkaline phosphatase activity (ALP) and enriched extracellular calcium deposition, we evaluated the effect of E1 on both parameters. E1 enhanced ALP (15% a/C, $p< 0,01$) and increased the number and size of calcification nodules in the extracellular matrix (one fold $p<0,005$, Alizarin staining), with major effect at longer period of cell culture. Accordingly with this, markedly decreased in calcium content was detected in aliquots of cultured medium (205±25 vs 118±23, C vs E1, $p<0,001$). Indeed E1 modulates extracellular collagen deposition visualized by Sirius red staining. On genes related with OB maturation, E1 treatment elicited 2 fold increase in Runx-2 mRNA levels, with higher effects at 3-5 days of culture ($p<0.05$). No changes were observed in BMP-2 expression. Similar results as that elicited by E1 were obtained when OB treatment were performed with the selective estrogen receptor modulator, raloxifene compound. In summary the results presented suggest that, E1 exhibits a positive action on bone, either on OB and extracellular matrix.

(1508) **DIFFERENTIAL ACTIONS OF TESTOSTERONE ON PROSTATE SMOOTH MUSCLE CELLS IN ACCORDANCE WITH THE SUBCELLULAR LOCALIZATION OF THE ANDROGEN RECEPTOR**

Nahuel Peinetti, Mariana Micaela Cuello Rubio, Carolina Leimgruber, Maria Victoria Scalerandi, Juan Pablo Nicola, Amado Alfredo Quintar, Cristina Alicia Maldonado
Centro de Microscopía Electrónica, Instituto de Investigaciones en Ciencias de la Salud (INICSA-CONICET), Facultad de Ciencias Médicas, Universidad Nacional de Córdoba, Córdoba, Argentina.

Testosterone (T) actions in prostate smooth muscle cells (pSMCs) are critical for prostate homeostasis and the development of pathological conditions. T can operate through the classical cytoplasmic androgen receptor (AR) eliciting genomic signaling, or via receptors located at the plasma membrane for nongenomic signaling. Here we aimed to evidence nongenomic T signaling in pSMCs and their role in cell proliferation, differentiation, and modulation of lipopolysaccharide (LPS)-induced response. For this purpose rat pSMCs were stimulated with T or BSA-conjugated T (T-BSA). To analyze modulation of LPS-response, pSMCs were stimulated with LPS, LPS+T or LPS+T-BSA. ANOVA-Tuckey was used for statistical analysis

Membrane localization of AR in pSMCs was determined by confocal microscopy and flow-cytometry with anti-AR antibody, and verified by western blot (WB) of isolated cell surface proteins. Furthermore, we showed that pSMCs can respond to T or T-BSA by nongenomic activation of ERK1/2 and Akt phosphorylation, as evidenced by WB. Membrane stimulation with testosterone resulted in AR- and pERK- dependent increase in cell proliferation (Ki67 and total cell count) which was determined by the use of specific inhibitors ($p<0.05$). Besides, pSMCs stimulated with T-BSA presented higher proliferation as compared to T ($p<0.05$). Membrane stimulation also favored smooth muscle phenotype by increasing their markers (calponin, α-smooth muscle actin) and decreasing vimentin (WB) ($p<0.05$). In the contrary, we showed that the anti-inflammatory effects of T are promoted only by the cytosolic AR which decreased LPS-induced TNFα and IL-6 levels (ELISA) ($p<0.05$), and NF-κB nuclear translocation (immunofluorescence) ($p<0.05$).

We postulate that T might perform pro-homeostatic effects in pSMCs by modulating cell proliferation and inflammation through classical intracellular mechanisms, while pathological, hyperproliferative actions would be induced by membrane-initiated nongenomic signaling.

(1422) **ESTRADIOL WOULD FAVOR INDIRECTLY MAMMARY GLAND ELONGATION AND SIDE-BRANCHING BY STIMULATING PROGESTERONE RECEPTOR EXPRESSION IN PREGNANT *LAGOSTOMUS MAXIMUS* (RODENTIA: CHINCHILLIDAE).**

María Clara Corso, Sofía Proietto, Santiago Andrés Cortasa, Schmidt Alejandro Raúl, Pablo Ignacio Felipe Inserra, Santiago Elías Charif, Verónica Berta Dorfman, Alfredo Daniel Vitullo, Julia Halperin
CEBBAD Universidad Maimónides

Prolactin (PRL), progesterone (P) and estradiol (E2) are major regulators of mammary gland (MG) tissue remodeling throughout the repeated cycles of pregnancy-lactation-regression. Considering

the atypical modulation of the hypothalamus-hypophysis-ovary axis of *Lagostomus maximus* we studied the relation among P and E2 serum values, their MG-receptor expression levels (PR, ER and PRLR) and their relation with the MG-cell proliferation and MG-vascularization. P and E2 serum levels (ELISA) and mammary PRLR-, PR-, VEGF- and PCNA expressions (PCR and immunohistochemistry) were determined in 4 groups of adult vizcachas (resting, pregnant, lactating, regressing). Maximal levels of E2 and P were recorded at pregnancy ($p<0.005$) when the GM reaches a great development evidenced by high levels of both VEGF and PCNA. In order to establish the importance of the ovarian steroids over PRLR, PR, VEGF and PCNA expressions, adult non-pregnant females were ovariectomized (OVX) and treated with either E2 (OVX_E) or P (OVX_P). OVX animals were used as controls. Mammary PRLR immunoreactive area in OVX_E dropped approximately to half of that detected in OVX group ($p<0.005$) suggesting that the expression of this receptor is P dependent. On the contrary, the absence of changes in the expression of VEFG and PCNA among the experimental groups could indicate that the regulation of these markers is not under the direct and unique control of ovarian steroids but rather that they would coordinate their action with other factors (i.e. PRL) in MG-tissue remodeling. Interestingly, both PR gene expression and PR immunoreactive area were notably lower in MG of OVX_P compared to both OVX_E and OVX groups ($p<0.005$) indicating the role of E2 in PR expression. Our data suggest that the increased PR expression associated to the branching and elongation of the MG ductal tree at pregnancy may be indirectly stimulated by E2. Fundación Científica Felipe Fiorellino, CONICET-PIP110/14, MINCyT-PICT1281/2014

(722) **ESTROGEN AND PROGESTERONE MEDIATE DENDRITIC SPINE FORMATION THROUGH THE ACTIN REGULATORS CORTACTIN AND WAVE-1**

Ivonne Denise Uzair, Marina Ines Flamini, Angel Matias Sanchez
Lab. de transducción de señales y movimiento celular. IMBECU-CCT-CONICET Mendoza.

Pyramidal neurons from cortex and hippocampus have thousands of dendritic spines (DS) that form excitatory synapses. As a consequence, failures in DS formation can lead to an improper cognition, a common feature in neurodegenerative diseases like dementia. Actin nucleation is a fundamental process in DS formation and it depends on actin regulators. Among them, WAVE1 and Cortactin are key activators of the Arp2/3 complex, ultimate responsible for DS formation. Our previous research has established that 17β-estradiol (E2) and progesterone (P4) modulate several signaling pathways leading to WAVE1 phosphorylation and DS formation. However, the precise molecular mechanisms of this regulation remain to be elucidated. Therefore, we asked ourselves firstly, if Cdk5 Kinase and PP2A phosphatase regulate WAVE1 phosphorylation (their target protein) in response to rapid treatments with E2 and P4. Secondly, we evaluated if Cortactin phosphorylation was affected by the same treatments. To test our hypothesis, we employed primary culture of embryonic rat cortical neurons, immunofluorescence and western blot analysis. Our results showed that, after treatments with E2 or P4 (10nM, 20min), the number of DS was significantly increased (over a 50% vs. CON, $p<0,05$), indicating that both hormones rapidly modified neuronal morphology. The increase in the number of DS was prevented by Roscovitine, a Cdk5 inhibitor, and mimicked by Okadaic Acid, a PP2A inhibitor. These changes were accompanied by a significantly increase of the phosphorylation patterns of $Cdk5^{Y15}$, $PP2A^{Y307}$ and $WAVE1^{S397}$ after E2 and P4 stimulation. Furthermore, we also determined that Cortactin mediates DS formation via a Rac1/PAK1 cascade, after E2 and P4 treatment. As a conclusion, our results suggest that E2 and P4 exert a dynamic regulation of neurons morphology by inducing a rapid activation of Cortactin and WAVE1. E2 and P4 can promote DS formation and therefore they contribute to synaptic plasticity processes.

Keywords: E2, P4, WAVE1, cortical neurons, dendritic spines

(1417) **ESTROGEN RECEPTORS ARE INVOLVED IN LUTEINIZING HORMONE (LH) PULSATILITY DURING PREGNANCY IN THE VIZCACHA, *LAGOSTOMUS MAXIMUS*.**

Sofia Proietto (1), Lorena Yankelevich (1), Santiago Elias Charif (1), Pablo Ignacio Felipe Inserra (1), Alejandro Raul Schmidt (1), Santiago Andres Cortasa (1), Maria Clara Corso (1), Noelia Di Giorgio (2), Victoria Lux-Lantos (2), Julia Halperin (1), Alfredo Daniel Vitullo (1), Veronica Berta Dorfman (1)
(1) CEBBAD, Universidad Maimonides. (2) IBYME.

The South American plains vizcacha shows ovulatory around mid-gestation enabled by a hypothalamic-hypophyseal-ovarian axis activity with elevated levels of serum estradiol (E_2) and gonadotropin-releasing hormone (GnRH). Considering that E_2 is involved in hypophyseal regulation, the aim was to study the action of E_2 receptors (ER) on luteinizing hormone (LH) secretion in the vizcacha during gestation. We used hypophyses of early- (EP), mid- (MP), and term-pregnant (TP) vizcachas to study GnRH receptor (GnRHR), ER alpha (ERa), ER beta (ERb), and LH expression by Western-blot and immunohistochemistry, and LH pulsatility by RIA (n=6 / group). In order to evaluate the action of ER on LH secretion, LH pulsatility was studied in hypophyses of ovulating females incubated with ERa and ERb antagonists, or ERa and ERb agonists supplementation. Hypophyses without supplementation were used as control (CTL). ANOVA followed by Bonferroni was used to determine significant differences among groups ($p<0.05$). A significant decrease in LH pulsatility was observed in TP vs MP and EP, and this was concordant with variations in serum LH. Hypophyseal expression of GnRHR and ERa showed significant increments at MP vs EP and TP. In addition, ERb expression levels did not change during gestation. The colocalization analysis of ERa with GnRHR showed a decrease in MP vs EP and TP, whereas the colocalization of ERa with LH showed a concordant increment with pregnancy progression. Regarding to the involvement of ER in LH secretion, LH pulsatility showed significant decrease with ERa or ERb specific agonists vs CTL whereas the combination of both ER antagonists showed a decrement vs agonists effects. These results suggest that ER would enable LH pulsatillity in the vizcacha at mid-gestation as result of a hypophyseal sensibilization to GnRH input. Moreover, LH secretion during ovulation may require the action of both ERa or ERb isoforms. Fund. Científ. Felipe Fiorellino, PIP110/14, PICT1281/2014.

Estrogens regulate and play an important role in several physiological and pathological processes. The cellular effects produced by estrogens are mediated by two receptors: ERα and ERβ. The analysis of the ERs expression in PBMC may provide a useful tool to understand the responsiveness of these cells to estrogens and its association with certain pathologies, like chronic lymphocytic leukemia (CLL). In this study we investigated the relative expression of mRNA of both ERs in PBMC from healthy males and females between 25-90 years old. After informed consent, peripheral blood samples were obtained and PBMC isolates using Ficoll's gradient. RNA was obtained with Trizol reagent, and reverse transcribed. Real-Time PCR was performed using L19 as a housekeeping gene and statistical analyses were carried out using R software. We studied two groups of healthy donors for both genes: men and women younger than 40 and older than 60 years old. With regards to the ERs expression in women we found a significant difference only in the ERβ expression ($p=0,0312$), being higher levels for those donors older of 60. In males samples, there were significant differences in the two receptors and the higher levels for both were in donors <40 ($p=0,0105$ ERβ and $p=0,0330$ ERα respectively). When we compared both sexes the results obtained showed a marked difference in the expression of ERα, being higher for women >60 than men of the same

age (p=0,0037). Moreover, ERβ showed higher expression in men <40 (than women <40, p=0,0413), while women >60 showed higher levels than men of the same age (p=0,0043). These results demonstrate that the ERs expression in PMBC is a dynamical process, and the age and sex are important variables that influence the mRNA quantity. In the future, we are going to study mRNA expression of ERs splice variants and proteins in individuals with CLL taking into account that CLL is more frequent in people older than 50 years, and being men more susceptible than women.

In the pituitary, progesterone (P4) actions remain controversial because its effect depends on the hormonal milieu and the receptor types involved. Our previous results demonstrated that, besides the nuclear progestin receptors (nPRs), all membrane progestin receptors (mPRs) subtypes (α, β, γ, δ, ε) are also expressed in the anterior pituitary of female Sprague Dawley (SD) rats, being the mPRα the most abundant. In the present work, we observed by IF and Flow citometry that 65% of lactotrophs express mPRα. Focusing on the role of mPRα in the lactotroph physiology, we first performed a single-point competitive binding assay to demonstrate that P4 and the mPRα specific agonist Org OD 02-0 (02), significantly displaced [^{3}H]-P4 binding in plasma membranes of GH3 cell line, whereas the nuclear PR agonist R5020 was ineffective. Next, we demonstrated, in *ex vivo*-incubated SD-female pituitaries, that P4 100nM and 02 100nM, but not R5020 10nM decreased PRL secretion in medium (measured by RIA) and increased PRL content in the pituitary. We also observed the inhibitory effect of P4 and 02 on PRL release in GH3 cells, and again, R5020 was ineffective. We next assayed putative second messengers involved. We found that both P4 and 02 induced a significant decrease in cAMP accumulation. The inhibition of 02 on PRL release was blocked by pre-treatment with pertussis toxin (PTX 2,5ug/ml). In addition, 15min-treatment of P4 and 02 induced a significant increase in ERK phosphorylation, while R5020 did not. Finally, since TGFβ1 is one of the main inhibitors of lactotroph function, we evaluated whether this system could be regulated by mPRα, mediating in part, the effects of P4 on PRL secretion. In fact, P4 and 02, but not R5020, increased active TGFβ1 levels, measured by ELISA, in *ex vivo*-incubated SD-female pituitaries, and also in *in vitro* GH3 cell-culture. All these results provide the first evidence of specific mPRα involvement in the control of lactotroph function.

Abstract: Previously it was shown that estrogen receptor (ER) β increased the tumoral suppressor PTEN expression to modify the lactotroph and somatotrophs population growth and adequately respond to cyclic PRL y GH requirement during the estrous cycle. Expanding these investigations, the aim of this work was to analyze the ERα and β effects on PTEN/PI3K/Akt in the pituitary tumoral growth regulation mechanisms.

To carry out this objective, female rats treated with estradiol benzoate during 20, 40 and 60 days (hyperplasic/adenomatous pituitary model) and transfected GH3 tumoral cells (GH3 ERα+/ERβ- and GH3 ERα+/ERβ+) stimulated with E2 or ERα (PPT) and β (DPN) agonists were used. PTEN, Akt, p85α of PI3K, D1 cyclin and CDK4 expression was determined by western blot, the subcellular localization was visualized using confocal microscopy, the cell cycle progression was analyzed by flow cytometry and the cellular proliferation was quantified by BrdU technique. Statistical analysis: ANOVA-Tukey.

During the hyperplastic/adenomatous process development the PTEN protein expression showed cytoplasmatic distribution with significant reduction in its levels: at 20 days of tumoral development a reduction of approximately 50% was observed, being almost undetectable at 60 days. Akt, p85α and cell cycle regulator proteins D1 cyclin and CD4 significantly increased in relation with tumoral development, in agreement with the rise of proliferative phase cell number (S+G2/M). In GH3 ERα+/ERβ-, PTEN was found mainly in the peripheral cytoplasm with Akt phosphorylation and cellular proliferation increase. In contrast, in GH3 ERα+/ERβ+ cells a nuclear PTEN signal was found, reinforced with DPN stimulation, with decreased of mitogenic activity.
